THE authors have prepared benzenesulphonyl-*p*-phenylenediamine, toluene-*p*-sulphonyl-*p*-phenylenediamine, and toluene-*p*-sulphonyl-*m*-phenylenediamine by heating the appropriate nitraniline (*p*- or *m*-) with benzene- or toluene-*p*-sulphonic chloride for 4–5 hours in boiling toluene. (Toluene-*p*-sulphonic chloride is obtained as a by-product in the manufacture of saccharin.) After removal of the solvent the condensation product is extracted from the residue with aqueous sodium hydroxide and the solution acidified. The precipitated nitro-compound on reduction yields the base required (e.g. $\text{C}_7\text{H}_7\text{SO}_2\text{NH}\cdot\text{C}_6\text{H}_4\text{NH}_2$) or if first methylated and then reduced, the corresponding aminosulphon-methylamide (e.g. $\text{C}_7\text{H}_7\text{SO}_2\text{N}(\text{CH}_3)\cdot\text{C}_6\text{H}_4\text{NH}_2$) is obtained. The diazo-chlorides obtained from these six bases are stable and sparingly soluble in water; azo-dyestuffs were obtained by combining them with β -naphthol-6-sulphonic acid, β -naphthol-3:6-disulphonic acid, α -naphthol-4-sulphonic acid, H acid, and chromotropic acid. From a comparison of these dyestuffs with

those obtained from the same naphthol acids and ordinary diazo-compounds, the following conclusions are drawn: (1). The introduction of an arylsulphonyl group, $\text{NH}\cdot\text{SO}_2\text{R}$, into the para-position with respect to the azo-group produces an effect on the colour of the dyestuff comparable with that induced by the nitro-group in the same position. (2). The effect is somewhat diminished by the replacement of hydrogen by methyl in this group when occupying the para-position. (3). The presence of the arylsulphonyl group in the meta-position to the azo-group has no appreciable effect on the tinctorial properties of the dyestuff. (4). Considered as wool dyestuffs, the azo-sulphonamides and their methyl derivatives resemble the standard azo-dyestuffs in their fastness to light and scouring; they are, however, more completely removed from the dye-bath than the ordinary azo-dyestuffs containing the same phenolic residue. (5). As silk dyestuffs these azo-sulphonamides and azo-sulphonmethylamides are superior in their fastness to soap to the ordinary azo-dyestuffs containing the same phenolic residue. (6). The azo-sulphonamides and their methyl derivatives possess in a marked degree the tendency to assume the colloidal condition.—J. C. C.

Dyestuffs; Preparation of new, primary products for —. Report of sealed packet No. 746 (deposited Oct. 10, 1903) of J. Walter, by E. Noelting. Bull. Soc. Ind. Mulhouse, 1909, 79, 30–32.

NOELTING reports that, by oxidising Sun Yellow, Walter has isolated a benzaldehydesulphonic acid which is probably a mixture of the nitro-, azo-, azoxy- and possibly also the nitroso-derivatives. This acid condenses with dimethylaniline and gives, on oxidation, a green dyestuff. If it is first reduced to the leuco-base and this is oxidised, a blue dyestuff results which has the constitution,

—J. C. C.

Sulphinic acids; Isolation of the —. J. Thomas. Chem. Soc. Trans., 1909, 95, 342–345.

IN the preparation of aromatic sulphinic acids from diazo-compounds by means of sulphur dioxide and finely-divided copper according to Gattermann's method (this J., 1899, 675), the sulphinic acids are generally separated from the solution and the copper residue by extraction with ether. The author finds that separation can be effected much more simply by means of the ferric salts of the acids. All the aromatic sulphinic acids tried are precipitated quantitatively as orange-coloured ferric salts from strongly acid solutions on addition of ferric chloride. On decomposition with alkalis, the ferric salts yield ferric hydroxide and a solution of alkali sulphinate, from which the free sulphinic acid can be precipitated by addition of concentrated hydrochloric acid. A solution of the sulphinic acid in sodium carbonate when treated with sodium hypochlorite yields the corresponding sulphonyl chloride, and the sulphonamide may be obtained by decomposing the ferric sulphinate with ammonia, and then treating with sodium hypochlorite.—A. S.

PATENTS.

Dyestuffs; Manufacture of brown sulphurised —. A. G. Bloxam, London. From Chem. Fabrik Griesheim Elektron, Frankfurt a/M., Germany. Eng. Pat. 4848, Mar. 3, 1908.

By heating aromatic meta-dinitro compounds, or derivatives thereof which contain no hydroxyl groups, with polyhydric alcohols, or carbohydrates, and alkali polysulphides, dyestuffs are produced which dye unmordanted cotton in brilliant brown shades. That the polyhydric alcohols take part in the reaction, is evidenced by the fact that some of these meta-dinitro compounds yield olive-green dyestuffs when heated alone with an alkali polysulphide.—F. M.

Leuco-hydroxyanthraquinones; *Process for preparing* —. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 207,668, Jan. 26, 1908. Addition to Ger. Pat. 148,792, Feb. 1, 1903.

p-AMINOHYDROXY- or *p*-diaminoanthraquinones, either unsubstituted or with only heteronuclear substituents, are reduced by means of alkaline reducing agents to the corresponding leuco compounds, which are then converted into leuco-hydroxyanthraquinones by heating with dilute acids.—T. F. B.

Mono-aryldio-galloylanines; *Process for preparing leuco derivatives of* —. Farbwerke vorm. L. Durand, Huguenin, und Co. Ger. Pat. 207,670, March 11, 1908. Addition to Ger. Pat. 207,669, Aug. 1, 1907.

INSTEAD of reducing galloylanine arylides by aid of heat, in presence of excess of acid, as in the original patent (see Fr. Pat. 394,136 of 1908; this J., 1909, 239), the reduction may be carried out in the cold, in acid solution, by means of suitable reducing agents, e.g., zinc.—T. F. B.

Benzaldehyde-m-azo-2-naphthylamine-5.7-disulphonic acid; *Process for preparing a colourless reduction product, which cannot be diazotised, from* —. L. Cassella und Co. Ger. Pat. 207,935, Sept. 11, 1907.

THE yellow dyestuff, obtained by combining diazotised *m*-aminobenzaldehyde with 2-naphthylamine-5.7-disulphonic acid, is converted by treatment with mineral acids, into a reddish compound which, when reduced by means of zinc dust, stannous chloride, hydrosulphites, etc., preferably in presence of a bisulphite, forms a colourless substance, only slightly soluble in hot water and which cannot be diazotised. It can be used in the preparation of azo dyestuffs; for example, when melted with alkali hydroxides it gives valuable hydroxyl derivatives.

—T. F. B.

Vat dyestuffs of the anthracene series; *Process for preparing* —. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 208,162, Feb. 6, 1908.

SUBSTITUTED dianthraquinone-imines, which dye blue, violet, and blue-black shades from the vat, are obtained by the condensation of halogenated anthraquinone derivatives with aminoanthraquinones in presence of metallic salts, the anthraquinone derivatives containing auxochrome groups which are in the *o*- or *m*-position to the imino-group in the resulting compounds. Thus, 6 kilos. of 1-hydroxy-3-bromoanthraquinone and 2.5 kilos. of 1.4-diaminoanthraquinone are dissolved in 60 kilos. of nitrobenzene, and heated for 6 hours at 180° C., after addition of 4 kilos. of sodium acetate and 500 grms. of cupric chloride; the dyeings are violet.—T. F. B.

Vat [thioindigo] dyestuffs; *Process for preparing* —. Kalle und Co. Ger. Pat. 208,343, Sept. 20, 1907.

By oxidation of arylthioglycolic acids in alkaline solution by means of chlorine, arylsulphoxyacetic acids,

are obtained. By treating such of these acids as have a free *o*-position to the sulphoxyacetic group, with concentrated sulphuric acid, monohydrate, or sulphuric acid chlorohydrin, with or without other substances assisting condensation (e.g., boric acid), vat dyestuffs of the thioindigo group are obtained. The yields vary considerably; whilst phenylsulphoxyacetic acid gives very small yields of dyestuff, some of its derivatives, especially the halogen derivatives, give much higher yields.—T. F. B.

Sulphonic acid of Celestine Blue; *Manufacture of a* —. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 11,867, June 1, 1908.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Sisal hemp; *Composition and utilisation of pulpy waste from the stripping of* —. A. Hébert and F. Heim. Compt. rend., 1909, 148, 513—514.

IN stripping the fibres of the *Agave rigida Sisalana* for the preparation of sisal hemp, a large proportion of the weight of the leaf is left in the form of a pulpy waste composed of the fleshy and epidermal tissues. The dried pulp contains about 12 per cent. of mineral matter and 11 per cent. of total sugars calculated as dextrose. The question of fermenting the pulp for the manufacture of alcohol deserves consideration, but the obvious and immediate application of this waste is to return it to the land in the form of manure. The harvesting of 100 kilos. of fresh leaves removes from the soil: 0.24 kilo. of phosphoric acid, 1.14 kilos. of lime, 0.62 kilo. of potash and 0.16 kilo. of nitrogen. Analyses of the dried fibres and dried pulp gave the following results:—

	Fibres.	Pulp.
	per cent.	per cent.
Mineral matters	8.02	12.11
Phosphoric acid	0.41	0.16
Lime	1.94	3.57
Potash	1.06	1.22
Total nitrogen	1.78	3.79

Unless these fertilising constituents are returned to the soil as far as possible, the plantations will tend to become exhausted. One hundred parts of green leaves yield 27.7 parts of dry pulpy waste. If this waste be used as a manure, it will only be necessary to compensate for the fertilising matters removed in the fibrous portion of the crop.—J. F. B.

Acid Magenta printed upon sulphur bleached wool; Development of — when exposed to direct sunlight. D. Paterson. J. Soc. Dyers and Col., 1909, 25, 112—113.

WHEN Acid Magenta, without the addition of any acid, is printed on worsted yarn, the resulting faint, undeveloped colour becomes, on exposure to sunlight, a full Magenta if the yarn has been bleached with sulphurous acid. A non-sulphured yarn does not show this reaction. The author points out that sulphured yarns retain sulphur dioxide even after prolonging washing and drying, and considers that the development of colour observed is due to the oxidation under the influence of sunlight of the sulphur dioxide to sulphuric acid. A similar effect is noticed in the case of wool which has been printed with lead acetate and steamed; the brownish drab shade produced is quite fast to sunlight, but if sulphured wool has been used, the sulphuric acid developed turns this grey and ultimately white, the lead sulphide (to which the colour is due) being converted into lead sulphate.—J. C. C.

Starches: Determination of the value of —. A. Binz and T. Marx. Chem. Ind., 1909, 32, 167—169.

MANY investigations upon starch paste have been published, dealing chiefly with the viscosity, or adhesive power of comparatively thin pastes. These points are of interest to the calico-printer, but are not of such moment in finishing or in the laundry, where it is the filling or stiffening power of the paste which is important. The values of starches in this respect are compared by determining the resistance which the paste offers to the removal of a plate of a given size, embedded in it at a certain depth. The paste is prepared by stirring 33 grms. of starch with 50 c.c. of cold water and adding 350 c.c. of boiling water. A round brass plate, 22 cm. in diameter, with a brass rod fixed to its centre, is then lowered into the liquid so that it lies 3 cm. below the surface. The paste is left to cool for about 20 hours, being covered with a thin layer of olive oil to prevent the formation of a "skin." The rod attached to the plate is connected to the arm of a balance and sand is gradually poured into the scale pan suspended from the other arm until the plate is lifted vertically out of the paste. The weight of the sand serves as a measure of the stiffness of the paste. The results obtained with stiff pastes from rice starch are useful as to the comparative values of these for finishing and laundry purposes; for calico-printing thinner pastes would have to be compared. The apparatus, as described, is not suitable for the comparison of pastes made from potato and wheat starches.—F. M.

Carrageen moss. E. Hastaden. Färber-Zeit., 1909, 20, 107—109.

CARRAGEEN or Irish moss is an alga of the Atlantic Ocean which is collected on the shores of Ireland and Scotland; it has been confounded by some writers with Iceland moss, a land lichen, which is totally different and is scarcely adapted for textile finishes. Carrageen moss is not sufficiently adhesive for laundry purposes, but for certain textile finishes it is capable of giving most valuable effects at a very low cost. It does not give hard finishes. For goods which have to be calendered under heavy pressure, Irish moss is of no practical importance, since the finish breaks down in the calendering, but for very lightly dressed goods, such as sateens, lanellas, zephyrs, etc., it has recently come considerably to the fore in producing the so-called "natural finish." It imparts a bulky "handle," with a high degree of softness and an absence of a "papery" effect. A 0.75 per cent. decoction of Irish moss is particularly good for dressing raised goods like flannelettes in which heavier dressings tend to lay the nap and to dust out during the raising process. As the jelly mixes readily with all the other finishing materials, its scope of usefulness is very wide. It has the advantage of preventing to a large extent the bleeding of the dyestuffs in washing. The temporary unpopularity of Irish moss was probably largely due to unsuitable methods of preparing the jelly and the lack of suitable antiseptics. The best qualities are nearly white in colour, the inferior grades being dark grey; the latter give an inferior yield of jelly, a large proportion being insoluble.

A good quality of moss should be selected, steeped for 12 hours, and boiled for 2 hours; inferior qualities require twice as long at both stages. The jelly requires an antiseptic to overcome its liability to putrefaction; suitable proportions are 3–5 grms. of salicylic acid or 33 grms. of formaldehyde per 100 litres of decoction.—J. F. B.

PATENTS.

[Artificial threads, etc.]. Albuminoids; Process of dissolving — and its industrial applications. H. L. J. Chavassieu. Fr. Pat. 395,402, Dec. 27, 1907.

PROTEINS such as fibrin, casein, etc., are dissolved by means of caustic alkalis, and the solution treated with carbon bisulphide. The xanthates so obtained are used, either alone or mixed with cellulose xanthate, for the preparation of artificial threads, etc.—A. S.

Dyeing and dyes [dyestuffs] for use therein. C. Fowler, Liversedge. Eng. Pat. 4624, Feb. 29, 1908.

CLAIM is made for a process of dyeing union fabrics (cotton and wool, cotton and silk) in one bath, the vegetable fibre being dyed in one shade and the wool or silk in another. The dyestuff is made by mixing a direct cotton dyestuff with one which dyes wool, for instance, in a neutral bath, or with a dyestuff which dyes the wool in an acid bath. The dyestuffs chosen must, however, not react with or mutually precipitate each other. They may be used alone or in conjunction with one or more of the acids and salts usually employed in dyeing.—F. M.

Dyeing, scouring, and analogous machines. C. R. Kershaw, J. H. Abell, and B. Leach, Leicester. Eng. Pat. 6893, Mar. 28, 1908.

AN endless brattice conveyor, arranged at the delivery end of a dyeing or scouring machine, is supported along its length by side arms which in turn are mounted by means of pivots on fixed frames so that one end of the conveyor can be lowered into the vat of the machine. The brattice is also provided with projecting fingers which, when the conveyor is in action, pick up the material contained in the vat, carry it to the end of the path of the conveyor and deliver it into a suitable receiver. (See Eng. Pats. 1923 of 1862, 12,919 and 18,966 of 1891, and 12,545 of 1905; this J., 1906, 632.)—P. F. C.

Dyeing yarn; Apparatus for —. C. Corron, St. Chamond, France. U.S. Pat. 915,939, March 23, 1909.

THE skeins of yarn suspended from reels mounted eccentrically on shafts carried by a frame and driven by electric motors, are alternately lowered into and raised out of dye-baths by an automatically controlled hydraulic ram.

—W. H. C.

Organic substances; Process for the reduction and oxidation of — by electrolysis. H. Chaumat. Second Addition, dated Dec. 28, 1907, to Fr. Pat. 393,561, Oct. 29, 1907.

THE process described in the main patent (this J., 1909, 148) and in Fr. Pat. 379,041 (this J., 1907, 1196) for the reduction of indigo, is now applied to the reduction of indanthrene dyestuffs, especially indanthrene and flavanthrene, for the purpose of preparing vats for dyeing purposes. By applying the process to mixtures of indigo and flavanthrene in varying proportions, vats can be prepared yielding different shades of green. It is stated that in this process of reduction, the quantity of alkali used can be so diminished, that it becomes possible to use the indanthrene colours for dyeing wool.—A. S.

Dithionalkylthioindigo dyes on vegetable fibres; Process for treating —. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pats. 206,567, July 30, 1907, and 206,568, March 3, 1908.

VEGETABLE fibres dyed with dithionalkylthioindigo dyestuffs deteriorate after long exposure to light; this tendering may be avoided by treating the dyed fibres with solutions of copper salts or iron salts, which treatment also increases the fastness of the dyeing considerably. The dyestuffs are obtained, for example, from *p*-amino-

nitrobenzoic acid, which is converted by means of the diazo reaction into ethylthionitrobenzoic acid; this is reduced, the amino-acid treated with chloroacetic acid, and the product melted with alkali and oxidised to 6,6'-diethylthioindigo.—T. F. B.

Printing with gallocyanine dyestuffs; Process for —.
Anilinfarben und Extrakt-Fabr., vorm. J. R. Geigy.
Ger. Pat. 207,323, March 5, 1908.

GALLOCYANINE dyestuffs have formerly been used for printing only in the form of their bisulphite compounds or leuco-derivatives. It is now proposed to use them in their solutions in presence of aromatic sulphonic acids or their salts, e.g., naphthalenesulphonic acids.—T. F. B.

Drying, cooling, etc., of textile fabrics, warp yarns, etc.; Method of and means for the —. J. Charlesworth, Huddersfield. Eng. Pat. 4992, Mar. 5, 1908.

THE invention relates to apparatus for forcing hot or cold air against or through the fabric, warp yarn, etc., whilst this is passing through one, two, or more chambers. Each chamber is supplied centrally with a fan for circulating the air, and the heated or cooled air is forced to pass through the material as this is led around the fan. In the case of fabrics, these are held at full width by pins or clips on endless chains, which pass around a pair of revolving discs arranged in each chamber at a suitable distance apart. Or, as in the case of warp yarns, the material may be supported by laths, bars, or rollers, which fit into sockets in these revolving discs.—F. M.

Bowling material which has been dyed or printed with vat colouring matters. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 14,337, July 6, 1908.

SEE Fr. Pat. 392,858 of 1908 this J., 1909, 89.—T. F. B.

VII.—ACIDS, ALKALIS, SALTS, AND NON-METALLIC ELEMENTS.

Ammonia; Synthesis of — from its elements. J. Lipski. Z. Elektrochem., 1909, 15, 189—206. (Compare this J., 1905, 545.)

THE yield of ammonia, prepared synthetically with the aid of cerium nitride or hydride, is considerably greater than has hitherto been obtained by similar processes, the volume of ammonia in the gas stream easily reaching 1 per cent., as against 0.1 per cent. or less by other methods. The reactions,

$3\text{H}_2 + \text{CeN} = \text{CeH}_3 + \text{NH}_3$ and $\text{N}_2 + \text{CeH}_3 = \text{CeN} + \text{NH}_3$, take place at atmospheric pressure, and at low or medium temperatures without interference from the reaction.

although at high temperatures, when the dissociation pressures of the nitride and hydride are greater and the stability of ammonia is small, the last reaction predominates; the temperature most favourable to the formation of ammonia by this process is 200°—300° C. The gases used must be absolutely pure and dry, traces of moisture or oxygen affecting the surface of the material and rendering it useless, but the nitride or hydride may be prepared either from the pure metal or from commercial material. By employing nitrogen and hydrogen alternately, a continuous production of ammonia takes place, but the material becomes exhausted eventually and requires time for its recovery. The maximum dissociation pressure of cerium nitride at 600°—700° C. is 34—40 c.m., but equilibrium is retarded by a slow, continuous increase of pressure, which appears to depend partly on the formation of a solid solution of cerium and its nitride, and partly on lack of homogeneity and the age of the sample.—F. SODN.

Potassium perborate. C. von Girsowald and A. Wolokitin. Ber., 1909, 42, 865—869.

A 75 per cent. solution of potassium metaborate containing an excess of potassium hydroxide is added to

10 times its volume of 3 per cent. hydrogen peroxide; after eight hours the liquid is filtered and to the filtrate is added nine-elevenths of its volume of methyl alcohol. The precipitated salt is filtered off after twelve hours, washed twice with ice-cold water, and dried in the air. It has the composition represented by $2\text{KBO}_3 \cdot \text{H}_2\text{O}$; is but slightly soluble in cold, rather more so in warm water. The solution behaves like a mixture of borate and hydrogen peroxide, and loses oxygen slowly in the cold, more rapidly on warming. The salt is insoluble in alcohol or ether. If 30 per cent. hydrogen peroxide be used instead of the 3 per cent. solution, a salt of the composition, $2\text{KBO}_3 \cdot 11\text{H}_2\text{O}$, is obtained, similar in general properties to the other.—J. T. D.

Barium carbide; Action of nitrogen on commercial —.
O. Kühling and O. Berkold. Z. angew. Chem., 1909, 22, 193—197.

THE authors have already shown that addition of barium chloride has only a slight influence on the absorption of nitrogen by a heated mixture of barium carbonate and carbon (see this J., 1908, 121). Similar experiments with commercial barium carbide have now shown that addition of barium chloride (10, 20, and 30 per cent.) neither reduces the initial temperature of nitrogen-absorption appreciably, nor causes much increase in the total quantity of nitrogen absorbed, and that this salt appears to cause an increase in the yield of cyanide at the expense of cyanamide. The interpretation of the results is rendered much more difficult by the impurity of the carbide used, which had the following composition:—Barium, 49.86; calcium, 17.11; iron and aluminium, 2.62; carbide carbon, 7.62; sodium, 0.85; chlorine, 0.18; portion insoluble in hydrochloric acid, 9.76; phosphorus, sulphur, oxygen, and carbon dioxide, 12.0 per cent. The authors conclude that the material was not free from calcium carbide. Moissan showed that even at so high a temperature as 1200° C., pure barium carbide absorbs scarcely any nitrogen. With the crude carbide used by the authors, absorption began at 500°—600° C., the maximum absorption being attained at 920°—930° C. Since the added chloride is inactive, the catalytic action of the oxides must be considered, though which of these are especially active cannot be decided at present. To prevent risk of explosion, the following modification of the usual method was adopted for determining the carbide carbon in the barium carbide used:—About 20 grms. of the dry carbide were placed in a vacuum flask (of about 1 litre capacity), the bottom of which was covered with previously ignited sand. The side tube of this flask was connected by a thick-walled rubber tube to a stop-cock tube fitting the upper outlet of an aspirator (of about 6 litres capacity) filled with acetylene water; the lower outlet of this aspirator was connected by a thick-walled rubber tube with a second aspirator. The neck of the vacuum flask was fitted with a rubber stopper carrying a dropping funnel. After adjusting the level of the liquid to a mark on the neck of the first aspirator, the stop-cock tube was joined to the rubber tube leading to the vacuum flask, and the second aspirator was placed in as low a position as possible; 50 c.c. of 96 per cent. alcohol and then 100 c.c. of 80 per cent. alcohol (previously saturated with acetylene) were now added from the dropping funnel, the flask being shaken towards the end of the reaction, and the volume of gas evolved subsequently determined. For the determination of cyanide in the product, Feld's method (Ber., 1907, 40, 314) was found to be not directly applicable owing to the acetylene in the distillate; the method used was as follows:—The material (0.5—0.6 gm.) was distilled with 30 c.c. of saturated lead nitrate solution and 80—100 c.c. of water (Feld), the distillate being collected in 25 c.c. of N/1 sodium hydroxide. The alkaline solution was treated with excess of ammoniacal silver solution. After about 10 minutes, the silver acetylide was filtered off; nitric acid was added, drop by drop, to the filtrate, which was stirred throughout this operation (any rise of temperature being avoided), until all the silver cyanide was precipitated and the solution was just acid. The precipitate was washed with cold water, dried at 100°—110° C., and weighed. It was found that in determining the cyanide

in the products obtained between 570° and 730° C., a yellow, nitrogen-free, highly explosive substance, only partially soluble in cold, concentrated nitric acid, was obtained on treating the alkaline solution with ammoniacal silver solution.—L. E.

Cuprous oxide; Electrolytic precipitation of —. D. Miller. *J. Physical Chem.*, 1909, **13**, 256–261.

By the electrolysis of hot solutions of sodium chloride between copper electrodes, precipitates consisting of cuprous oxide and hydroxide, in varying proportions, are obtained, the intense red forms being nearly pure cuprous oxide and the yellower varieties containing more of the hydroxide. The colour of the precipitate also depends on the size of its particles, the larger the particles, the darker being the colour. The larger particles are obtained at the higher temperatures and by slow precipitation; the same general rules of precipitation hold therefore whether a substance is precipitated chemically or electrolytically. Addition of glycerin to the electrolyte causes the cuprous oxide to be precipitated in the amorphous form, the colour varying from brownish-red to greenish-yellow.—F. Sodx.

Ferric nitrates at 25° C. F. K. Cameron and W. O. Robinson. *J. Physical Chem.*, 1909, **13**, 254–255.

Ferric nitrate solutions of various concentrations were shaken with freshly precipitated ferric hydroxide at 25° C. for 4 months, at the end of which time the clear solutions and the precipitates with adhering solution were analysed; the acid branch of the isotherm was also studied in like manner, starting with ferric nitrate and varying amounts of nitric acid. The results, examined in the light of the phase rule, show that there are no definite basic nitrates formed at this temperature, the so-called basic salts being solid solutions of ferric oxide, nitric acid, and water, but that, when the nitric acid is in excess (more than 30 per cent. of nitric anhydride), the normal nitrate, $\text{Fe}_2\text{O}_3 \cdot 3\text{N}_2\text{O}_5 \cdot 18\text{H}_2\text{O}$, is formed. On two occasions, with concentrations approaching 55 per cent. of nitric anhydride, crystals of an acid salt, $\text{Fe}_2\text{O}_3 \cdot 4\text{N}_2\text{O}_5 \cdot 18\text{H}_2\text{O}$, were obtained.—F. Sodx.

Titanium nitride. O. Ruff. *Ber.*, 1909, **42**, 900.

In preparing titanium nitride by Wöhler's method from titanium dioxide and ammonia, a temperature of at least 1000°–1100° C. is necessary, and it is preferable to work at 1400°–1500°. Even then, 4 to 6 hours are required before the conversion into nitride is complete. Pure titanium nitride cannot be completely decomposed by boiling with potassium hydroxide solution; the nitrogen is best determined by Dumas' method, the substance being burnt with cupric oxide in a porcelain tube at 1000° C. in a stream of carbon dioxide.—J. T. D.

Hydrogen and carbon monoxide; Pyrogenetic oxidation of — by contact action. G. Orlov. *Ber.*, 1909, **42**, 895–897.

HYDROGEN and air were passed in different proportions and at different speeds over platinum or copper, heated to the temperature at which combination begins, and then kept at that temperature by the heat evolved in the reaction. The initial concentrations of hydrogen and oxygen being called, c and c_1 , respectively, and that of the steam formed, c_2 , the experiments show that $c^2c_1/c_2 = 0.55$ approximately, whatever the speed of passage of the gases. In the case of carbon monoxide and air, the ratio of carbon dioxide to carbon monoxide in the issuing gases varies inversely as the cube of the speed of passage.—J. T. D.

Chlorine prepared from hydrochloric acid and potassium permanganate. Purity of —. E. Wedekind and S. J. Lewis. *Chem. Soc. Proc.*, 1909, **25**, 59.

CHLORINE, prepared from hydrochloric acid and potassium permanganate by Graebe's method (this *J.*, 1902, 284), is completely absorbed by mercury and gives the same value on titration as the gas obtained from hydrochloric acid and manganese dioxide; it is therefore considered to be free from other gases. The absence of traces of

the oxides of chlorine may be shown by acidifying the liquid remaining after titration with potassium iodide and thiosulphate, when no further liberation of iodine takes place, unless the permanganate contain chlorate.—F. Sodx.

Sulphur; Flames of phosphorescence and combustion of —. L. Bloch. *Compt. rend.*, 1909, **148**, 782–783.

It has previously been shown that phosphorescence, ionisation, and ozone-formation, accompany the oxidation of phosphorous anhydride to phosphoric anhydride, but not that of phosphorus to phosphorous anhydride (*Compt. rend.*, 1908, **147**, 842). The author has now found that ozone is formed during the phosphorescence of sulphur, and at a temperature at which this gas (ozone) is generally said to decompose (200°–250° C.). The production of ozone is much greater with sulphur than with phosphorus during phosphorescence. If the temperature is not too high, the gases leaving the tube containing the phosphorescent sulphur possess a strong odour of ozone but none of sulphur dioxide. At temperatures below that of phosphorescence, the gases possess a camphor-like odour. It was found that the phosphorescence is due, not to the combustion of a lower oxide of sulphur to sulphur dioxide, but to the combustion of sulphur vapour; the above-mentioned camphor-like odour appears to be due to sulphur vapour. The author confirms the statement of Elster and Geitel that the phosphorescence of sulphur is not accompanied by ionisation. At a temperature of about 360° C., phosphorescence gives place to the blue flame of burning sulphur; this flame does not produce ionisation, but does produce numerous centres of condensation. The oxidation of sulphur dioxide to sulphuric anhydride by atmospheric oxygen in presence of spongy platinum does not produce ionisation. The author concludes from this that with reference to ionisation, there is no analogy between the two degrees of oxidation of sulphur and of phosphorus. Seeing that the phosphorescence of phosphorus is accompanied by ionisation, whereas the flame of sulphur is perfectly non-conducting, it seems that the ionisation of ordinary flames is not due to high temperature, but to particular chemical actions.—L. E.

PATENTS.

Sulphur; Furnaces for the combustion of mineral —. G. Oddo, Pavia, Italy. *Eng. Pat.* 21,253, Oct. 8, 1908. *Under Int. Conv.*, Oct. 8, 1907.

Two furnaces are claimed. The first is a hand-operated furnace comprising five superposed storeys forming an upward zigzag path for the air and sulphur gases. The sulphur is fed into the central storey, the hearth of which contains a passage for the circulation of cold air, in order to prevent excessive rise of temperature and the decomposition of calcium carbonate with consequent loss of sulphur as calcium sulphide and sulphate. The residue is worked through the lower storeys of the furnace so as to heat the air, which is admitted to the lowest storey, in order that the sulphur gases may be hot enough for the regular working of the Glover tower. The other furnace is adapted for mechanical operation. The furnace is circular and comprises four storeys. The sulphur is fed automatically from a hopper by an external conduit to the second storey from the bottom, and is worked through the lowest storey by radial rotating arms mounted on a vertical spindle. (See also this *J.*, 1908, 222.)—A. T. L.

Copper sulphate; Manufacture of —. D. Watson, T. Ashall, and The United Alkali Co., Ltd., Liverpool. *Eng. Pat.* 12,812, June 15, 1908.

By causing sulphuric acid to run at intervals over divided copper, or copper shot, carried upon an inclined bed heated

from beneath by steam, the production of copper sulphate solution is rapidly effected, and the process can be carried out with a much smaller stock of copper, said to be one-sixth of that required in the ordinary tower process.—H. H. S.

Aluminates; Manufacture of alkaline ——. D. A. Peniakoff, Selzaetes, Belgium. Eng. Pat. 14,707, July 10, 1908. Under Int. Conv., Jan. 29, 1908.

IN manufacturing sodium aluminate by the calcination of bauxite, sodium sulphate, and carbon or sulphides, the sulphurous acid evolved is so diluted with air and fire-gases that it is difficult to utilise for the recovery of sodium sulphate or the manufacture of sulphuric acid. The patentee finds that the greater the mass under treatment, the more continuous the operation of calcining, the more the masses are kept in motion during calcination, and the more completely that combustion is effected in contact with the mass, the less will be the quantity of fuel necessary and the more sulphurous acid will be in the resulting gases. He achieves these conditions by a furnace comprising a long revolving tube which is heated by burning powdered coal or gas or oil therein.—H. H. S.

Aluminium oxide; Process for the electrolytic production of ——. F. W. Morris, Victoria, B.C., Canada. Eng. Pat. 6449, March 23, 1908.

VIII.—GLASS, POTTERY, AND ENAMELS.

Glasses and minerals; Action of oxidising and reducing gases on the colour of ——. W. Hermann. Z. anorg. Chem., 1908, 60, 369—404. Sprechsaal, 1909, 42, 172—173.

A NUMBER of coloured glasses were prepared by dissolving small quantities of metallic oxides in borax or in sodium-potassium silicate. Copper oxide gave two blue glasses, a light blue and a darker blue. Manganic oxide gave brown to red-violet colours. Cobalt oxide gave a blue borax glass with a tinge of red, but pure blue silicate glasses. Potassium bichromate gave a grass-green, ferrous oxide a grey-green, and ferric oxide a yellow glass. A mixture of ferrous and ferric oxide with very little manganic oxide gave a fine sky-blue colour on heating for some time in a Bunsen flame. Uranium oxide (1.5—2 per cent. of U_2O_3) gave a pure yellow borax glass, and a greenish-grey silicate glass. Cerium oxide gave a yellowish glass, titanium oxide a light yellow. Titanium oxide also gave an amethyst-violet colour to microcosmic salt, probably due to titanium nitride; the same colour was obtained on adding titanium oxide and ammonium chloride to a borax bead. The above glasses and a number of minerals were heated to dull redness in currents of air, oxygen, coal-gas, sulphur vapour, hydrogen, nitrogen, ammonium chloride vapour, and ammonia. The glasses suffered no change in colour on heating in air. Heating in oxygen rendered the ferrous oxide glasses darker and nearly black; the presence of both ferrous and ferric oxide was shown microscopically; the ferric oxide and uranium oxide glasses became paler, the cerium oxide glasses darker; the titanium oxide glass was decolorised with separation of grey particles at the edges. Heating in coal-gas rendered all the iron oxide glasses black, and manganic and chromium oxide glasses lighter in colour. Heated in sulphur vapour, the iron oxide glasses became black, and the chromium oxide glasses yellow-grey-green. Heated in hydrogen, the ferric oxide and cerium oxide glasses became darker, the ferrous oxide glass black, the manganic oxide glass received a dark red tint, and the uranium oxide glass became paler. Heating in nitrogen and ammonium chloride produced practically no change; heated in ammonia, the ferrous oxide glass became paler,

and the chromium oxide glass nearly decolorised. As regards the minerals, heating in air rendered the green zirconos light grey, with rust-red spots; the brown zirconos and hyacinths became paler or colourless, or remained unchanged. Grey quartz, "citrin," and amethyst became colourless. Yellow corundum became darker on heating, but regained its colour on cooling. Dark yellow topaz was decolorised on heating, but became rose-red to red-violet after cooling. Blue and violet Stassfurt rocksalt became colourless, dark violet and blue-green fluorspar showed green fluorescence on heating, and became colourless at a low red heat. Nearly the same results were obtained on heating the minerals in oxygen. Heated in coal-gas, the green zirconos, pyropes (Bohemian garnet), and almandin (red garnet) became darker; the yellow hyacinths paler or reddish-violet; amethyst, citrin and grey quartz, colourless; Zillerthal garnet, dark brown; beryll, grey; emerald, paler; epidote, light green; rocksalt and fluorspar behaved as in air. Heating the minerals in sulphur vapour, hydrogen, nitrogen, ammonium chloride vapour, and ammonia gave nearly the same results as heating in coal-gas. From the above results the author forms conclusions as to the impurities which determine the colours of the minerals. Thus the colour of the green zirconos is probably due to ferrous oxide and chromium; the presence of chromium has also been shown spectroscopically. The two oxides of iron also cause the colours of corundum, spinell, epidote, and beryll, and probably of quartz, tourmaline, and topaz. Chromium and manganese oxides influence the colours of zircon, corundum, garnet, tourmaline, and probably quartz and topaz. The rare elements, uranium, cerium, etc., only affect the colours of minerals to a slight extent. Organic substances, e.g., hydrocarbons, constitute the colouring matter of some minerals.—A. G. L.

PATENTS.

Glass; Method of and apparatus for drawing ——. O. Imray, London. From Window Glass Machine Co., Pittsburg, Pa., U.S.A. Eng. Pat. 23,968, Nov. 9, 1908.

IT is found that, by adjusting the pot and drawing tool relatively to each other in a lateral direction, so that the draw can be started from any particular point on the surface of the molten glass, a more uniform thickness in the cross-section of the article can be obtained. In this way irregularities, arising from differences in the surface tension of the glass at various distances from the sides of the pot, can be overcome. Thus if the glass be at a lower temperature at one side of the bath than at the opposite side, the blowpipe is moved towards the hotter portion. In the arrangement provided, the blowpipe with the bait is arranged on a support which is itself capable of moving horizontally on a square travelling frame by means of arms fitting into threaded sleeves in the latter. By means of a cable attachment a vertical movement can be imparted to the whole frame. It is also provided that the pot itself can be adjusted in position if necessary, and, to that end, it is mounted on bearings which, by means of screws, can be moved in any direction. Finally it is claimed that the invention extends to any other method of controlling the surface tension of the glass such as adjustment of the level of the fused mass in the pot.—C. A. W.

Sheet glass; Apparatus for the manufacture of ——. F. M. Oppermann, Namur, Belgium. U.S. Pat. 915,879, March 23, 1909.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Iron concrete; The cause of the disappearance of rust in ——. Rohland. Tonind. Zeit., 1909, 33, 382—383.

SOME time ago the author called attention to the disappearance of rust in iron concrete, and suggested that it might be due to the action on the ferric oxide of the calcium hydroxide, set free during the mixing of the

concrete, but by itself the hydroxide does not act upon the ferric oxide. Besides calcium hydroxide, colloidal aluminium hydroxide and silica have to be considered, but the latter has no solvent action upon ferric oxide, which is also unattacked by calcium and aluminium hydroxides. Any carbonic acid derived from the air would only dissolve ferrous oxide, but not ferric oxide. The author has found, however, that ferric oxide is acted upon by basic carbonates, solutions of which contain the HCO_3 -ion, and still more energetically by acid sulphates, solutions of which contain the HSO_4 -ion. Gypsum, a solution of which contains the SO_4 -ion, does not act upon ferric oxide. Iron can be detected in solution, when ferric oxide has been in contact for a few hours with an aqueous solution of carbonic acid to which some normal sodium or potassium sulphate has been added. In the same way ferric oxide is acted upon by a solution of calcium hydroxide, to which an aqueous solution of carbonic acid has been added, in sufficient quantity to redissolve the carbonate first formed. The disappearance of rust in iron concrete can be thus explained, and the necessary conditions occur in the setting and hardening of cement. During the mixing, setting, and early stages of hardening of cement, atmospheric carbon dioxide is absorbed by the water used for mixing, and then adsorbed by the colloidal silica and aluminio-ferric hydroxide set free. At the same time lime is set free and gives rise to an acid carbonate or to the HCO_3 -ion, and as all Portland cements contain gypsum and some alkali sulphate, presumably HSO_4 -ions are also formed. The iron oxide is slowly dissolved by these reagents. The rate of reaction is slow, because the ions have to be formed from a gas and a liquid, carbon dioxide and water, and have then to react with a solid, ferric oxide. Even after 24 hours' contact with a slow-setting cement, the rust on some badly corroded rods became thinner, and some parts were cleared. The same rods were placed in a new cement, and when withdrawn, it was found that the loosely adherent ferric oxide had decreased, and beneath it was a thin black coating of magnetic oxide. After several days' contact with new cement, the whole of the rod was freed from rust, except between the points of contact of the iron and cement, where oxygen had access. Hence the reaction between the acid calcium carbonate, or the HCO_3 -ion, and the ferric oxide occurs during the mixing with water, the setting and the early stages of hardening. Of the base metals, iron alone can form a non-corrosive union with cement, because it remains unoxidised in contact with alkaline liquids, whereas the other base metals are oxidised, and a strong alkaline reaction is developed in cement on mixing. Clean iron consequently is protected from oxidation by cement, and any rust present diminishes in time, and in this way iron concrete is entirely protected.—W. C. H.

PATENTS.

Cement. T. Jones, Acme, Tex., Assignor to Acme Cement Plaster Co., Illinois. U.S. Pat. 916,165, Mar. 23, 1909.

The cement is prepared by calcining a mixture of gypsum and normal aluminium sulphate at a red heat, and then mixing it with the product (in the form of a dry powder) obtained by the action of sulphuric acid on potassium bisilicate dissolved in water. The final composition of the cement is: Calcium sulphate, 1020 lb.; basic aluminium sulphate, 30; dry gelatinous silica, 14; and potassium sulphate, 11 lb.—A. G. L.

X.—METALS AND METALLURGY.

Cast iron; The air-furnace process of preparing white cast iron for the production of malleable — H. M. Howe and E. Touceda. Bull. Amer. Inst. Min. Eng., 1909, 317—326.

The removal of metalloids from the iron, and the alteration of the composition of the slag at various stages of the

process are shown both by tables and graphically. The curves obtained are discussed with special reference, in the case of the metal, to the constancy of the silicon-content (0.89 per cent. after 2½ hours to 0.87 per cent. after 5½ hours). It is pointed out that the low temperature should have favoured the removal of silicon, and that the acidity of the slag was not great enough to explain its slow removal. The authors consider that this constancy of the silicon content is due mainly to the low percentage of silicon in relation to that of carbon. In support of this view a large number of data from the open-hearth process are given, showing that in all cases where the removal of silicon between two successive samples was very small, the silicon-content was also very small, either absolutely or relatively to the carbon content. The details of the process are given in an appendix.—A. H. C.

Grading assays and grinding efficiencies. A. Yates. J. Chem. Met. and Min. Soc. S. Africa, Dec. 19, 1908. [Advance proof.]

The paper deals with the value of grading assays in connection with estimating the crushing efficiency and relative merits of machines, in addition to their use in checking extraction results in the cyaniding of gold ores. The crushed material is graded by passing it through a series of sieves of known aperture, and the "efficiency number," representing the relative surface exposed, is obtained by dividing the weight of each product by the average diameter of the particles. The "efficiency number" for the whole crushing is the sum of the efficiency numbers of the products. In order to make the figures more readily comparable in cases where the power and tonnage vary, the relative efficiency is calculated by multiplying the grading efficiency by the tonnage and dividing by the horse power. A number of tables are given showing the relative efficiencies of stamp batteries with and without tube mills in conjunction, and also the effect of varying the aperture of the battery screens. A number of tables showing the practical use of grading assays are also included.—F. R.

Copper ores; Basic converter process for — F. Schreyer. Metallurgie, 1909, 6, 190—197.

ATTEMPTS have been made during the last few years to use converters with basic linings for copper ores, the silica necessary to slag the ferrous oxide being added in the form of sand. The advantage claimed for the process consists in greater rapidity of working, but the higher temperature necessary to render the basic slag produced sufficiently liquid necessitates the use of air enriched in oxygen, or at least of air under high pressure. Even so, the loss in copper, due to mechanical inclusion of copper sulphide in the viscous slag, is considerable. The author determined the melting-points of solutions of ferrous sulphide in mixtures of ferrous and ferric oxides, the mixtures containing about 5 per cent. of sulphur; such mixtures are more easily fusible than the oxides alone, but their melting-points still lie above 1300° C. Moreover, in practice it would be difficult to obtain such slags with a constant percentage of sulphur. When working with air considerably enriched in oxygen, the iron of the ore is oxidised to a state approximating to magnetic oxide; with lower percentages of oxygen in the air used, the iron oxide formed approximates to the formula, $\text{FeO} + \text{Fe}_3\text{O}_4$ (possibly Fe_4O_5); below this stage of oxidation the iron oxide has little action on the undecomposed sulphides of the ore. Probably the basic converter process will be useful only to obtain a regulus from poorer ores, not for the smelting to metallic copper.—A. G. L.

Corroded metals. W. P. Jorissen. Chem. Weekblad, 1909, 6, 150—153. Chem. Zentr., 1909, 1, 1050—1051.

A SAMPLE of "Delta metal" which had been exposed for a long time to the action of sea-water, was found to contain 52.7 per cent. of copper, 41.1 of cuprous oxide, 1.4 of water, 2 of substances insoluble in nitric acid, and 2.8 per cent. of other substances soluble in nitric acid, consisting of compounds of lead, iron, and zinc, and residual salts from the sea-water. The action of the

sea-water had thus resulted in the practically complete removal of zinc from the original alloy, which consisted of 45—55 per cent. of copper and 40—45 of zinc, together with small proportions of lead, iron, and manganese. Copper immersed for two years in sea-water became coated with cuprous oxide. In a piece of iron which had lain in the soil for several years, there was a distinct difference between the outer and inner layers of the metal. The former (sp. gr. 2.11), on treatment with hydrochloric acid, left a residue of 45.4 per cent., of which 19.6 per cent. was dissolved on treatment with chromic anhydride and sulphuric acid, whilst for the inner layer (sp. gr. 2.53) the corresponding figures were 35.1 and 16.1 per cent. respectively.—A. S.

PATENTS.

Furnaces for volatile metals. W. Hommel and The Metals Extraction Corporation, Ltd., London. Eng. Pat. 27,018, Dec. 6, 1907.

THE furnace consists of a chamber divided by a horizontal partition of refractory material, extending nearly the whole length. Ore is fed into the front part of the upper chamber, and means are provided for shifting it along to the back where it falls into the lower chamber and is shifted to the front, into a rectangular blowing hearth, fitted with a grate, and rotatable on a horizontal axis. The ore is preheated on its way to the blowing hearth, by the gases passing to the flues. When the hearth has been freshly charged, a suitable quantity of coal is added, and air blown through the grate into the furnace chamber. At first highly carbonaceous gases are given off which are allowed to escape to the stack, but when the zinc or other metals are volatilised and burnt to oxide, the flue leading to the stack is closed and that leading to the condensing chamber opened. The blowing hearth is discharged by partly rotating it on its axis.—F. R.

Zinc; Extraction of — from ores and zinc residues. W. Hommel and The Metal Extraction Corporation, Ltd., London. Eng. Pat. 27,020, Dec. 6, 1907.

ZINC ore, preferably roasted, is mixed with a certain proportion of zinc works residues, which contain a large proportion of coke or carbonaceous matter with varying amounts of zinc, lead, etc., and ignited in a furnace or blowing hearth, the zinc being blown off as oxide. The impure oxide is treated with sulphurous acid to form zinc bisulphite, from which the zinc is precipitated as mono-sulphite and then calcined to zinc oxide. The patent is a modification in detail of Eng. Pat. 23,901 of 1907 (this J., 1909, 26).—F. R.

Gold; Extraction of — from its ores, and apparatus therefor. A. M. G. Schillot and L. Maclaure, Paris. Eng. Pat. 5841, Mar. 16, 1908.

THE ore is reduced at the outset to the condition of slimes which will pass through a screen having a mesh of some

thousandths of a millimetre. It is stated that the portion of the metal which remains behind in the mortars and accumulates can afterwards be removed in the metallic state without the use of mercury. The cyaniding apparatus for the slimes comprises an inclined channel of semi-circular cross-section which diminishes in radius from one end to the other. This channel is divided into compartments by partitions, these last being arranged to support a horizontal shaft which runs along the whole length and carries the stirrer arms. The latter are of special design, being fitted at the ends with wooden spoons so that, in the revolution of the shaft, bubbles of air are imprisoned and forced down into the body of the solution. The slimes, introduced near the top of the channel, pass down the slope through the compartments, meeting on the way the cyanide solution as the latter is forced upwards. The exhausted ore is finally collected in boxes at the bottom, whilst the solution of gold passes away over the inclined plane at the top.—C. A. W.

Precious-metal bearing material; Process of treating —. S. S. Sørensen and G. C. Westby, Murray, Utah. U.S. Pat. 914,680, March 9, 1909.

THE precious metals contained in solutions, obtained in the treatment of copper ores in the wet way, are precipitated by bringing the solution into contact with crushed iron or copper mattes.—F. R.

Furnaces for metallurgical purposes. P. Schmelzer, Metz. Germany. Eng. Pat. 18,523, Sept. 3, 1908. Under Int. Conv., Nov. 4, 1907.

THE invention consists in providing auxiliary means of heating furnaces by building into the walls, preferably below the level of the molten bath, composite plates connected to a source of electricity. The plates are composed of an ordinary conductor faced with a refractory material, not attacked by the charge in the furnace, and which is a conductor of electricity at high temperatures. The refractory facings to the plates become highly heated owing to their electrical resistance, which, together with the heat caused by the passage of the current through the bath, augments the temperature produced by the principal source of heat. It is suggested that this principle might also be advantageously adapted to Bessemer converters.—F. R.

Furnace; Ore-smelting —. J. T. Jones, Iron Mountain, Mich., Assignor to Jones Step-Process Co., Minnesota. Re-issue, No. 12,928, March 16, 1909, of U.S. Pat. 890,232, June 9, 1908.

THE furnace consists of a combination of a carbonaceous fuel burning furnace and an adjoining chamber having an ore stack of smaller cross-sectional dimensions, rising out of its roof, and through which ore is charged into the chamber. A flue the walls of which are formed of solid carbonaceous material, leads from about the middle of the fuel furnace to a point in the ore chamber near to its junction with the ore stack.—F. R.

Ore-smelter. E. A. Mathers, Assignor to D. H. Harner, Philadelphia, Pa. U.S. Pat. 916,176, Mar. 23, 1909.

A FURNACE is arranged with a rotary roaster above it and a rotary smelter alongside the furnace. The smelter is provided with a stationary part, close to which both roaster and furnace discharge their products. The roaster is cone-shaped, with the long axis horizontal, the small end receiving the ore, and the large end discharging into a conduit leading to the smelter.—A. G. L.

Ore; Process of roasting and sintering —. A. S. Dwight, Assignor to F. Bennitt, Joliet, Ill. U.S. Pats. 916,396 and 916,397, Mar. 23, 1909.

ORE containing combustible material is roasted and sintered by causing it to move continuously in a layer in a horizontal direction. The ore is supported both at top and bottom by endless bands of perforated material. The ore is ignited at a point near the entry end, the combustion being supported by air entering through the lower supporting band and escaping through the upper. The supporting bands may also carry relatively large

fragments of rock or ore, which help to retain the finely-divided ore. In this case the large particles on the lower band are caused to agglomerate with the sintered product.—A. G. L.

Iron, soft steel, cast steel, and the like: Cementation of —. E. Jourard, St. Ouen, France. Eng. Pat. 23,958, Nov. 9, 1908.

THE pieces or articles to be hardened are placed in the casing ordinarily used for cementation and bedded in an intimate mixture of potassium ferrocyanide, 25; potassium bichromate, 10; ammonium chlorate, 5; chimney soot, 30; and horn powder, 30 per cent.; and maintained at a constant temperature of about 850° C. for the necessary amount of time. A file, with a layer of 5 mm. of the mixture, will be hardened to a depth of 1 mm. for each hour it is heated.—F. R.

Steel [vanadium alloy]. H. D. Booth, Assignor to The Midvale Steel Co., Philadelphia, Pa. U.S. Pat. 914,633, March 9, 1909.

THE steel contains 0.5–1.5 per cent. of copper and 0.1–0.6 per cent. of vanadium.—A. G. L.

Ores; Treatment of [finely divided] —. A. L. Dean, Queenstown, Tasmania, Assignor to The Mount Lyell Mining and Railway Co., Ltd., Melbourne, Australia. U.S. Pat. 914,391, Mar. 9, 1909.

FINELY divided sulphide or arsenide ores are screened and mixed. A portion of the ore is then charged on to a bed of previously ignited carbonaceous fuel. When this portion of the ore has become thoroughly ignited, the remainder is added, and the combustion continued "until the fire has penetrated the mass uniformly," the resulting mass being then removed from the furnace, and broken up into sizes suitable for further treatment in a blast-furnace.—A. G. L.

Wire and metal cleaning bath. J. C. Bencker, Pueblo, Colo. U.S. Pat. 914,916, March 9, 1909.

THE claim is for the use of an acid "pickling" bath containing arsenious oxide, with the result that iron and steel articles cleaned therein are coated with a protective film of metallic arsenic.—F. R.

Refining; Process of —. F. von Kugelgen and G. O. Seward, Holcombs Rock, Va., Assignors to Tin Products Co., New York. U.S. Pat. 915,029, Mar. 9, 1909.

TIN scrap is treated in a closed vessel with dry chlorine so as to form stannic chloride. By controlling the admission of chlorine and by cooling the vessel, the temperature is kept so low that the iron is not attacked and the volatilised stannic chloride is condensed within the vessel, the liquid formed being finally drained from the residue of iron scrap.—A. G. L.

Aluminium and aluminium alloys; Process of, and mould for, making castings of —. E. Blough, Parnassus, Pa., Assignor to Aluminium Co. of America, Pittsburgh, Pa. U.S. Pats. 915,727 and 915,728, Mar. 23, 1909.

TO increase the heat conductivity of the mould, the latter is made from ordinary foundry sand mixed with about 15 per cent. of finely-ground and dense carbonaceous material, which must be difficultly oxidisable and substantially non-volatile at the temperature attained, and which must not destroy the binding properties of the sand.—A. G. L.

Ores; Method of and apparatus for treating —. J. T. Jones, Iron Mountain, Mich., U.S.A. Eng. Pat. 5515, March 11, 1908. Under Int. Conv., May 22, 1907.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(I.)—ELECTRO-CHEMISTRY.

Storage batteries; Red lead for —. H. C. Frey. Electrical World, 1909, 53, 274.

RED-lead made by the old process (from metallic lead, in oxidising furnaces) is crystalline, dense, and liable to contain as much as 40 per cent. of litharge. The nitrite process yields an amorphous, and less dense red oxide, containing generally less than 10 per cent. of litharge. For accumulator electrodes the presence of 10 per cent. of litharge appears to be advantageous.

Electrolytic precipitation of cuprous oxide. Müller. See VII.

PATENTS.

Furnace; Electric —. S. F. Hall, Niagara Falls, N.Y., Assignor to Norton Company, Worcester, Mass. U.S. Pat. 914,489, March 9, 1909.

THE furnace consists of a furnace chamber, separable from the hearth, and containing spaced electrodes of opposite polarity hanging vertically and parallel to one another. The electrodes are separated by interior double walls, forming an open well, in order to obtain a more uniform temperature in the furnace.—F. R.

Electrolytic apparatus. O. Meyer, Richmond, Va. U.S. Pat. 914,856, March 9, 1909.

IN an electrolytic cell consisting of an upright cylinder closed at its extremities with caps, one electrode is wound round the exterior of a porous cylindrical vessel which stands within the cylinder, the top projecting through the upper cap. The other electrode consists of a tube passing downwards through the porous vessel nearly to its bottom, and which also serves to convey the electrolyte from a suitable container to the cell. Discharge outlets, to permit the escape of the products of electrolysis, are provided in the porous vessel and the outer cylinder.—F. R.

Electric accumulators; Process for regenerating —. C. Luckow, Cologne, Germany. U.S. Pat. 915,989, March 23, 1909.

SEE Eng. Pat. 11,353 of 1905; this J., 1905, 1072.—T. F. B.

Electric conductors. Eng. Pat. 17,620. See II.

(B.)—ELECTRO-METALLURGY.

Furnace; New electrical hardening —. E. Sabersky and E. Adler. Trans. Faraday Soc., March 30, 1909. [Advance proof.]

THE furnace consists essentially of a fire-clay crucible, in which a bath of molten salt, or salts, is heated by means of an alternating electric current, transmitted to the bath by two iron electrodes, the articles to be hardened being immersed in the bath. The salts being conductors of the second class (i.e., only conductors of electricity at high temperatures), when once the current has been started, the entire bath forms a conductor of decreasing resistance as the temperature rises, the latter being easily controlled by varying the voltage. The composition of the bath is varied according to the temperature required, a mixture of sodium and potassium nitrates being used for temperatures between 200° and 580° C., sodium and potassium chlorides from 650°–900° C., potassium and barium chlorides from 750°–1100° C., barium chloride from 1050°–1350° C., and calcium or magnesium fluorides from 1500°–1600° C. The uniformity of temperature throughout the bath, renders the indications of the pyrometer more reliable than when it is used on furnaces having an outside source of heat, and definite temperatures may more certainly be obtained and retained. This is of great importance in the case of modern high-speed tool steel, which may easily be spoilt by relatively small overheating. Another advantage of the furnace is, that although the thin edges of articles and portions having small cross-sections are heated more rapidly, the temperature of the bath prevents their overheating while the mass of the article is attaining the necessary temperature. The crucible is surrounded by asbestos and insulated, the whole being contained in a cast-iron case. Radiation losses are so small that the outer case only registers 30°–40° C. after the furnace has been working at 1350° C. for ten hours. The authors claim that, though the working costs are somewhat higher per hour than the ordinary gas-fired furnaces, the cost of treatment is considerably less on account of the increased output.—F. R.

Copper, lead, and silver; Effect of the presence of certain "addition-agents" upon the density and the coherence of electrolytically deposited —. R. P. Jarvis and E. F. Kern. School of Mines Quarterly, 1909, 30, 100–129.

THE well-known fact that the addition, to certain electrolytes, of small quantities of such substances as gelatin, tannin, etc., increases the density and coherence of the metallic deposit has been investigated by the authors. The electrolytes experimented with were cupric sulphate, cuprous chloride and cupric fluosilicate, lead nitrate and lead fluosilicate, and silver nitrate and silver fluosilicate. The electrodes used consisted of plates of the pure metal in each case, and the "addition-agents" employed were gelatin, resorcinol, pyrogallol, and tannin. It was found that the smoother and more coherent deposits tend to form when low current-densities are employed; that rise in temperature up to 60° C. tends to produce dense and coherent deposits; and that the deposits of lead, silver and copper formed in the fluosilicate electrolytes are more coherent than those produced in the nitrate electrolytes of lead and silver, or in the sulphate or chloride electrolytes of copper. The effect of the "addition-agents" was found to be as follows:—*Lead*.—In the nitrate electrolyte (nearly neutral) crystallisation of the deposited metal was restrained when an "addition-agent" was present to the extent of 1 part in 250 by weight, tannin having the greatest effect; but with this electrolyte the deposits obtained were in all cases unsatis-

factory. In the fluosilicate electrolytes, the presence of an "addition-agent" to the extent of 1 in 5000 caused the lead to deposit as a smooth, dense, coherent mass. Resorcinol was found to be unsuitable, while of the remaining "addition-agents" gelatin was the most, and pyrogallol the least, effective. *Copper*.—With sulphate electrolytes, pyrogallol was found to be unsuitable, causing the deposited copper to be dark in colour. In the presence of tannin, resorcinol, or gelatin a smooth, bright deposit was produced, tannin and gelatin being respectively the most and least effective. In the fluosilicate electrolyte, tannin, pyrogallol and gelatin improved the smoothness and brightness of the deposit, tannin giving the best result. The deposit of copper from the cuprous chloride electrolyte was not improved by the presence of any of the "addition-agents" or by elevation of temperature. *Silver*.—Gelatin, to the extent of 1 part in 10,000 or 14,000, produced shorter and smaller crystals in the metallic deposit, which was consequently more dense and coherent. Pyrogallol, tannin, and resorcinol were found to be unsuitable. 40° C. was found to be the most suitable temperature for the deposition of silver.

—W. E. F. P.

PATENTS.

[*Tin-plating iron.*] *Electrolytic process.* H. L. Hollis, Chicago, Ill. U.S. Pat. 916,155, Mar. 23, 1909.

AN electrolyte is first prepared, by passing a current from a tin anode through a solution of hydrofluosilicic acid in water to a suitable cathode, until the solution has become sufficiently rich in tin. The iron sheets to be tin-plated are then immersed in the solution as cathodes, and the passage of the current continued. A colloid may be added to the solution.—A. G. L.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

Irvingia butter. E. Bontoux. *Matières Grasses*, 1908, 1276–1278.

THIS vegetable "butter" or fat comes from the kernels of two Indo-Chinese trees of the family *Rutaceæ* or *Irvingiæ*; especially the *Irvingia Oliveri* (*I. Harmandiana*); and in Cambodia, the *I. malayana Oliv.* A tree of the same family growing on the west coast of Africa produces dika butter. The *Irvingia* flower in April; the fruit matures in July or August and is an oval drupe with fibrous mesocarp and woody endocarp; the size is that of a lemon, but the ripe fruit after losing its outer skin is a large almond-size. The pulp prepared from the kernels is twice extracted with steam and pressed. The fatty matter is allowed to cool, if intended for candles, in bamboo tubes provided with wicks. The press-cake is used for fodder, fertiliser or fuel. Five kilos. of nuts yield 1 kilo. of kernels and 430 grms. of the fat. Vignoli erroneously stated that this fat contained 30.2 per cent. of oleic acid and 68.5 per cent. of solid fatty acids including stearic acid. Hecker considered the fatty acids to consist of 30 per cent. of myristic and 70 per cent. of lauric acid. The author examined two samples of the butter made in Cochin China (II. and III.) and one prepared by himself in the laboratory from the fruit (I.). Sample I. was whitish, acid value 0.86; sample II. cream colour, acid value 23.5; sample III., pink, acid value 34.9. The acidity is not excessive, considering the age

of the samples, indicating good keeping qualities. Other characteristics are as follows:—

	Sample I.	Sample II.	Sample III.
Fat.			
Sp. gr. at 40°/10° C.	0.9133	0.9128	0.9130
Freezing point.....	31°	31.2°	31.8°
Melting point (capillary)	39.7	38.2	38.4
Unsaponifiable matter	0.42%	0.16%	0.19%
Saponification value...	235.3	236.3	237.4
Iodine value.....	6.7—6.8	4.1—4.2	4.0—5.1
Reichert-Meissl value.	0.62	0.75	0.70
Fatty Acids.			
Insoluble unsaponifi-			
able acids.....	91%	93.4%	93.2%
Titer value.....	39.6	—	36.4
Melting point.....	38.8	—	39
Neutralisation value...	250.2	—	253.0
Mean molecular weight	224	—	222

The methyl esters of the fatty acids were prepared and isolated by fractional distillation according to Haller's method; from the results of this test the composition of the butter is given as 5 per cent. of olein, 30—35 of laurin and 60—65 of myristin; it is thus similar to dika butter. The production is small at present, for though the butter makes excellent candles and white soap and is suitable for chocolate making or as edible vegetable butter, the great bulk of the fruit makes it difficult to handle.

Soaps: Detergent action of — W. Spring. Z. Chem. u. Ind. Kolloide, 1909, 4, 161—168.

From the results of experiments with purified lampblack and soap solutions the author concludes that carbon (lampblack) promotes the decomposition of fresh soap solutions in water. An acid salt (soap) is produced and the carbon combines with this to form an adsorption compound. When a soap solution is subjected to the action of an electric current, the soap is slowly decomposed, and particles of acid soap gather about the anode, whilst lampblack suspended in water travels towards the cathode. The constituents of the carbon-soap compound have thus a different electrical polarity in water. Lampblack, in the dry state or suspended in water, forms a more or less stable adsorption compound with solid substances and especially with cellulose. The colloidal combination between the carbon and cellulose is not decomposed by pure water. Thus, when an aqueous suspension of lampblack is filtered, the water passes through clear, and then, on reversing the filter-paper so that the lampblack is outside it is not possible to remove this lampblack from the paper by washing with water. On the other hand, lampblack suspended in aqueous soap solutions passes through filter-paper without blackening the paper. In the author's opinion, based on these and similar observations, the detergent action of soap must be attributed to a process of substitution due to the soap having a greater affinity for the dirt (lampblack) than the latter has for solid substances (e.g. cellulose). Thus, in the case mentioned, the adsorption-compound of the lampblack and cellulose (filter-paper) would be decomposed, the soap uniting with the lampblack.—C. A. M.

PATENTS.

Oil: Apparatus for extracting — V. J. Lauerman, Mineral Wells, Texas, U.S.A. Eng. Pat. 16,612, Aug. 7, 1908. Under Int. Conv., Aug. 7, 1907.

CLAIM is made for an apparatus consisting of a cylinder surrounded by a steam jacket and containing a rotatable shaft carrying spikes and blades, the latter parallel to its axis. Between these movable blades and the shaft are fixed blades against which the oil-seed is thrown and thence projected against the spikes. The material is thus thoroughly mixed and uniformly heated during its passage through the cylinder.—C. A. M.

Oil seeds: Process and apparatus for pressing — A. Austerlitz, Győr, Hungary. Eng. Pat. 7224, April 1, 1908. Addition to Eng. Pat. 10,860, May 9, 1907.

(B).—RESINS, VARNISHES.

Caucasian copal. E. Pyhälä. Chem. Rev. Fett- u. Harz-Ind., 1909, 16, 72.

FOSSIL resins discovered in 1907 in the vicinity of Schuscha in South Caucasus were found to contain copal resin. The fragments were either transparent and of about the size of a nut, or larger, more irregular in form, and opaque. They varied in colour from yellowish-brown to dark brown. The resin was very hard, and had a sp. gr. of 1.0574 at 18° C. It was devoid of odour or taste, but emitted an aromatic odour when burned. It began to melt above 200° C., but did not fuse completely below 250° C. Between 180° and 200° C. it became plastic. On dry distillation the transparent modification yielded 62.14 per cent. of distillate between 240° and 330° C., and left a residue of 18 per cent. of coke, whilst water and loss amounted to 19.86 per cent. The opaque modification yielded 58.75 per cent. of distillate, 26.25 per cent. of coke, and 15 per cent. of water (including loss). All the distillates separated by fractional distillation had an aromatic odour. The copal resin was insoluble in petroleum spirit, alcohol, and methyl alcohol; it dissolved with difficulty in turpentine oil; but was readily soluble in chloroform. The distillates from the dry distillation dissolved with difficulty in 95 per cent. alcohol, but were readily soluble in petroleum spirit, benzene, turpentine oil, and chloroform.—C. A. M.

Kauri copal: Solubility of — C. Coffignier. Bull. Soc. Chim., 1909, 5, 289—296.

FOUR types of Kauri copal from New Zealand are known in commerce. Pale Kauri or fossil copal is found in large masses varying from yellowish-white to clear yellow in colour. It has an aromatic smell, brilliant fracture, and is easily pulverised, forming a white powder. It has the sp. gr., 1.036; m. p., 165° C.; acid value, 70.9;

saponification value, 73. Brown Kauri is a fossil copal of a yellow brown or deep yellow hue; it is difficult to powder, has a conchoidal fracture, and an aromatic camphor like odour. It has the sp. gr. 1.053; m. p., 185° C.; acid value, 78.8; saponification value, 89.7. Bush Kauri is obtained at the foot of trees in irregular amber-like masses; it is easily powdered to a yellow powder with an aromatic odour. It has the sp. gr. 1.03; m. p., 150° C.; acid value, 83.1; saponification value, 78.5. Bush Kauri gathered from the trees themselves has a vitreous fracture; it has sp. gr. 1.038; m. p., 125° C.; acid value, 81.8; saponification value, 87. The behaviour of these copals towards a number of solvents, has been tested. In the following table the figures denote the percentage insoluble in the boiling solvent:—

Solvent.	Pale Kauri.	Brown Kauri.	Bush Kauri.	Gathered bush Kauri.
Ethyl alcohol	46.6	35.8	12.3	4.2
Methyl alcohol	46.9	61.9	47.3	34.2
Amyl alcohol	Soluble	Soluble	Soluble	Soluble
Ether	61.8	60.7	55.1	51.1
Chloroform	54.4	58.7	50.7	43.4
Benzene	66.7	70.6	61.7	57.6
Acetone	8.9	38.7	20.7	11.3
Turpentine oil	77.5	73.6	72.9	63
Beazaldehyde	Soluble	Soluble	Soluble	Soluble
Aniline	Soluble	Soluble	Soluble	Soluble
Amyl acetate	Soluble	2	Soluble	Soluble
Carbon tetrachloride	81.1	77.3	71.9	63

The marked solubility of pale Kauri in alcohol is contrary to the general experience. Brown Kauri is more resistant than pale Kauri.—E. F. A.

Resin; A liquid —. W. Fahrion. Z. angew. Chem., 1909, 22, 582—583.

A LIQUID resin, which has been called "tallöl," is obtained as a by-product in the preparation of cellulose from Swedish pine. It is a dark brown fairly fluid oil, readily soluble in alcohol, ether, and acetone, but incompletely soluble in benzene and oil of turpentine; it boils at 270° C. at 40 mm., sp. gr., 0.997 at 15° C.; acid value, 163. The oil is fairly stable, hardening very slowly on exposure, but its salts with the heavy metals dissolve in benzene and turpentine and harden rapidly. In composition it resembles colophony and gives similar products on dry distillation, but, unlike this substance, it is readily esterified by treatment with alcoholic sulphuric acid; it consists principally of resin acids of the formula, $C_{20}H_{30}O_2$, one of which is a solid. Hitherto the technical applications of tallöl have been limited.—F. SOHN.

Resin-tapping experiments in India. Board of Trade J., April 1, 1909. [T.R.]

ACCORDING to the Progress Report on Forest Administration in the Punjab in 1907, experiments are being made in resin-tapping on three sample plots in Kangra, with the object of ascertaining the yield from trees tapped to death and the time it takes to kill them. These experiments should be extended, as the resin industry has a great future, consequent on the approaching extensive utilisation of American resins for the manufacture of synthetic camphor, and the results obtained from them will be utilised in other divisions besides Kangra.

PATENTS.

Turpentine and rosin; Process for removing — from resinous woods. H. T. Yaryan, Toledo, Ohio. U.S. Pat. 915,400, Mar. 16, 1909.

THE wood is treated with a hydrocarbon solvent to extract the turpentine and rosin, and the bulk of the solvent subsequently removed from the extract by distillation (e.g., by means of a heating coil and separating chamber). The turpentine and remainder of the solvent are next separated from the rosin in a similar manner, whilst the solvent is separated from the turpentine by means of a rectifying column and condenser.—C. A. M.

Rosin; Process of purifying and treating —. H. T. Yaryan, Toledo, Ohio. U.S. Pats. 915,491 and 915,402, Mar. 16, 1909.

THE colophony is dissolved in a hydrocarbon or other suitable solvent, and treated with sulphuric acid, which precipitates the darker impurities. The supernatant liquid is treated so as to separate and recover the solvent and the rosin, whilst the precipitate is treated with water, and the rosin extracted with a suitable solvent from the curd-like mass obtained. The dilute sulphuric acid is subsequently concentrated by heating.—C. A. M.

Naphthalene and formaldehyde; Process for preparing condensation products from —. Badische Anilin und Soda Fabrik. Ger. Pat. 207,743, April 24, 1907.

PRODUCTS very similar to natural resins are obtained by treating 1 mol. of naphthalene with more than one-half mol., and preferably not much less than 1 mol., or even more, of formaldehyde or substances which generate formaldehyde, in presence of acids. The products have much higher melting-points than those obtained by treating naphthalene with one-third mol. of methylal in chloroform solution, in presence of sulphuric acid.

—T. F. B.

(C.)—INDIA-RUBBER.

Sulphur in vulcanised rubber; Determination of total —. M. Pontio. Caoutchouc et Gutta-Percha, 1909, 6, 2751—2752.

BERTRAND (Caoutchouc et Gutta-Percha, July 15, 1907) has stated that dry methods for the determination of sulphur in vulcanised rubber are inaccurate owing to loss of sulphur by volatilisation. The author has therefore tried the method proposed by him in 1904 (Rev. gen. Chim., Jan., 1904) and modified in 1908 (Caoutchouc et Gutta-Percha, July and August, 1908) with sulphur alone. A powdered mixture of 5 grms. of manganese dioxide, 10 grms. of sodium carbonate, and 15 grms. of potassium carbonate was prepared, and a portion of it was mixed with 100 mgrms. of powdered sulphur. Another portion of the oxidising mixture was placed on the bottom of a platinum crucible, the sulphur mixture was then introduced, and the whole covered with the remainder of the oxidising mixture. The crucible with the lid on was then gradually heated to redness in a muffle-furnace, and after $\frac{1}{2}$ hours, withdrawn, quickly cooled, and plunged into hot water. In the solution the sulphur was determined as barium sulphate in the usual manner. The results show that practically no sulphur was lost by volatilisation, 99.87, 99.2, and 99.73 per cent. respectively of the sulphur being converted into sulphate in three trials. The author states that by this method the total sulphur in vulcanised rubber can be determined to within 0.2 per cent.—A. S.

Rubber; Determination of organic and mineral impurities in raw and vulcanised —. M. Pontio. Caoutchouc et Gutta-Percha, 1909, 6, 2752—2753.

ONE of the methods proposed is based on the solubility of vulcanised rubber in cumene. The sample is suspended above a quantity of commercial cumene in a special flask provided with a reflux condenser and a filter, and the cumene is heated to boiling. The cumene vapour when condensed and containing dissolved rubber, passes through a small filter of calcined kaolin, which retains the insoluble impurities, back to the distilling flask. After about 12 hours, the filter and insoluble matter are removed, and washed with benzene, and with boiling 95 per cent. alcohol. The impurities in raw rubber or in rubber vulcanised but not loaded, can be determined by dissolving the caoutchouc in a suitable solvent and filtering the solution under pressure through a disc made of paper sold under the name of "paper for copper-plate engraving."—A. XIV.—TANNING, LEATHER, GLUE, SIZE.

Monascus purpureus, a fungus occurring in oil-dressing [of chamois leather]. A. Piedallu. Compt. rend., 1909, 148, 510—513.

It is well known that the oils used in the dressing of chamois leather undergo chemical changes whilst they are in the skins, and become brown in colour, acid in reaction, and considerably thicker. These changes are attributed to the action of micro-organisms, and particularly to the action of *Monascus purpureus*, a species of *Ascomycetes*, which the author has isolated from the oils used for dressing the skins. This fungus grows on various solid culture media, and its colonies ultimately develop a pink to dark purple colour. When cultivated on artichokes, the substratum below the pink colony acquires a greenish colour, owing to the action of an oxydase. If a drop of oil be placed on the surface of a growing colony, it is gradually invaded by the mycelium and coloured red; fish oils, however, are coloured orange to brown. Experiments made with Japanese fish oil, such as is used in leather dressing, showed the development of a yellow to brown colour, darker at certain points; the reaction of the oil became very distinctly acid and its consistence considerably thicker. Thus all the principal changes which occur in the oil in practical use were reproduced by means of pure cultures of this fungus. Similar results, but without the development of the red colour, were obtained in cultures in liquid media on which drops of various oils were floated. The characteristic changes which this fungus effects in the fish oils used in leather dressing may be due to the oxydasic ferment which it secretes, which is shown by the green coloration of artichoke tissue and a blue reaction with guaiacum tincture. —J. XV.—MANURES, &c.

Nitrogen compounds of the fundamental rocks. A. D. Hall and N. H. J. Miller. J. Agric. Sci., 1908, 2, Ann. Rep. Rothamsted Exp. Station, 1908, 8.

THE carbon and nitrogen compounds existing in the unweathered rocks from great depths, when subjected to the action of soil bacteria, are attacked; but they yield nitrate so slowly, that in all probability some of the nitrogen found in soils is that present in the rock from which the soil was formed and is not of recent origin. Ammonia and nitrates were found in all the rocks examined by the authors.—F. SONN.

Soils; Acidity of —. R. Albert. Z. angew. Chem. 1909, 22, 533—537.

THE author's method gives results agreeing with those obtained by the Süchting-Tacke method (this J., 1908, 171), and is much easier and more rapid in execution. Into a Jena conical flask holding about 1 litre, 20—50 grms. of the air-dried soil are put, and 200 c.c. of distilled water are added. Then a known volume (50—100 c.c.) of barium hydroxide solution of known strength is allowed to run in with the necessary precautions, 10 grms. of solid ammonium chloride are added, the flask is connected with a condenser, the ammonia set free by the barium hydroxide is distilled into N 10 sulphuric acid, and the residual acid is titrated with sodium hydroxide, using sodium alizarinsulphonate as indicator (which allows of titration in a hot solution). The amount of barium hydroxide neutralised by the acids in the soil can then be calculated. Acid silicates, as well as humic acids, are determined by this process. An indication of the quantity of humic acids in soil is afforded by shaking up the soil with water and adding a small quantity of lithium phosphate. Soluble "lithium humate" is formed by any free acid present, and the depth of colour of the solution is a guide to the amount of acidity.—J. T. D.

Soils; Nitrification in —. Pouget and Guiraud. Compt. rend., 1909, 148, 725—727.

ON the Algerian littoral during winter, nitrification is hindered by persistent rain. After such hindrance, however, nitrification is re-established only with difficulty; it commences towards the end of May, about a month after the rainy season. During summer, in a compact soil, nitrification takes place but denitrification also occurs; the nitric-nitrogen diminishes. Ploughing has a good effect in facilitating nitrification and preventing denitrification owing to the aëration to which it gives rise. In February, March, and April, in a compact soil such as that used for wheat, no nitrification takes place. During this period, however, the absorption of nitrogen by the wheat is most active; it is necessary therefore that the nitrogen-nutrition of wheat, during this interval, should be secured by the absorption of ammoniacal compounds.—J. C. C.

Azotobacter chroococcum, Beijerinck. S. Krzemieniewski. Anzeiger Akad. Wiss., Krakau, 1907, 746—749; 1908, 929—1051. Chem. Zentr., 1908, 1, 1198—1199; 1909, 1, 1029.

THE greatest fixation of nitrogen is obtained with nutrient solutions infected with fresh soil; oxygen and nitrogen are absorbed and carbon dioxide and hydrogen are evolved. When the nutrient solution is infected with a pure culture of *Azotobacter chroococcum*, less nitrogen is fixed, oxygen is absorbed abundantly, and carbon dioxide, but no hydrogen, is formed. If pasteurised or sterilised soil be added to the nutrient solution sown with the pure culture, the fixation of nitrogen is increased. The nitrogen-fixing power of the *Azotobacter* is increased by either soluble or insoluble salts of humic substances, but not by aqueous soil extracts prepared in an autoclave at 120° C. With pure cultures containing a constant quantity of dextrose, the fixation of nitrogen is proportional to the amount of humic acid salts present, whilst with a constant quantity of humic substances, it is proportional to the amount of sugar. Different results are obtained with humus from different soils, and the natural product cannot be replaced by artificial humus prepared from sugar and acids. The greatest fixation of nitrogen is obtained when 200 c.c. of nutrient solution contain 0.25—0.5 gm. of humic substances and 2.5 grms. of dextrose. Humus cannot be used alone as a source of nitrogen or carbon. As a source of carbon dextrose gives the best results; sucrose is less effective, and mannitol even less so. Soluble humic substances (sodium salts) are more effective than insoluble (calcium salts). The efficacy of natural humus is considerably diminished by boiling it with hydrochloric acid, a treatment which causes the solution of a considerable portion of the nitrogenous compounds of the humus. Humic substances cannot be satisfactorily replaced by other nitrogen com-

pounds (nitre, ammonia, amino-acids, and amides). For a consumption of 1 grm. of dextrose, the *Azotobacter* is capable of fixing up to 17 mgrms. of nitrogen. The most favourable temperature is 28° C.; at 9° C. the *Azotobacter* becomes inactive, whilst at 33° C. its activity is greatly diminished. The activity appears to vary with the origin of the organism, but is not affected by the presence of other bacteria. The ratio of carbon dioxide formed to oxygen consumed is always in the neighbourhood of 1, being somewhat greater than 1 in presence of dextrose, and somewhat less in presence of mannitol. *Azotobacter chroococcum* is distinctly aerobic; in pure cultures, neither acids nor alcohol are formed, and carbon dioxide is the only gaseous substance produced.

Calcium cyanamide; Gaseous compounds produced by the decomposition of — and their influence on plant growth. E. Haselhoff. Landw. Versuchsstat., 1908, 68, 189. Biedermann's Zentr., 1909, 38, 150—155.

WHEN calcium cyanamide was mixed with moist soil and subjected to the action of a current of air, 10 grms. yielded 0.068—0.077 grm. of ammonia in 8 days, and 0.0795 per cent. of acetylene in 3 days. 50 grms. yielded 0.00068 grm. of hydrogen phosphide in 3 days. Traces of hydrogen sulphide were also sometimes formed, but no hydrocyanic acid. Comparative experiments showed that the germination of seeds is affected injuriously by small quantities of ammonia, hydrogen phosphide, or hydrogen sulphide, but not by acetylene; whilst plant growth was retarded by ammonia and hydrogen phosphide, and to a lesser extent by acetylene and hydrogen sulphide.—A. S.

Ammonia; Manufacture of synthetic. —. E. Brönnert. Bull. Soc. Ind. Mulhouse, 1909, 79, 39—47.

THE author gives a description of Serpek's process for preparing aluminium nitride. Aluminium carbide is prepared by heating a mixture of carbon and alumina in the electric furnace. On treatment with water this carbide yields methane and when heated in a stream of nitrogen (generator gas) it is transformed into aluminium nitride. The carbide need not be isolated but is mixed with a further quantity of alumina and treated with nitrogen. The nitride contains 20—24 per cent. of nitrogen and can be used directly as a manure as, under the influence of water and atmospheric oxygen it evolves ammonia, alumina being also formed. The pure nitride contains 34 per cent. of nitrogen.—J. C. C.

XVI.—SUGAR, STARCH, GUM, &c.

Diffusion process [Sugar] in which the effect of the inactive space in the battery is obviated. E. Psenicka. Z. Zucker-ind. Böhm., 1909, 33, 308—310.

EVEN in the most modern methods of working the diffusion process the result is influenced by the inactive space in the battery and the author overcomes this disadvantage by his process as illustrated in the accompanying figure. The diffusion vessels, I. to V., are provided with the uptake valves, P_1 to P_5 , and the saturated juice valves, S_1 to S_5 . The valves below are worked as usual. The diffusion vessel, II., is filled with fresh chips and introduced into the diffusion process in the usual manner, but as soon as the juice in it has risen to the air vent, the current is reversed by reversing the valves, P_2 and S_2 , and simultaneously opening S_1 , when the juice from the inactive space of the diffuser, below the dotted lines, as

well as the weaker juice, which has only been slightly in contact with the fresh chips, streams into diffuser, III., filling the inactive space in this vessel, ready to come first into contact with fresh chips at the next mashing operation, thus realising an ideal and regular procedure in the contact of juice and fresh chips. Only so much juice is admitted into diffuser, III., that the juice drawn off into the measuring tank may be as high in density as possible, as determined by laboratory tests. When this quantity has been run in, the valve, S_4 , is closed and the dense juice passes to the measuring tank. About 90 per cent. of the harmful effect of the inactive space is obviated by working in this manner.—L. J. DE W.

[Sugar] Juices and syrups; Purification of — by aluminium and calcium silicates. J. Smahel. Z. Zucker-ind. Böhm., 1909, 33, 310—313.

THE process of Gans for purifying juices and syrups by filtration over natural zeolites or the artificially prepared silicate, "calcium permittite," permits of a partial replacement of potassium by calcium and, in consequence of the lower chemical equivalent of calcium, the ash of the juice is lessened and a higher quotient of purity apparently results. The introduction of lime into the juice by filtration over aluminium and calcium silicates however produces a series of undesirable results. The juices darken, are difficult to grain, require prolonged boiling, and give a smaller yield of sugar of inferior quality, and in consequence of the slow boiling, the total work is decreased. The author found in one case that when the juice had a quotient of 95 per cent. at 14° Balling, it contained 0.12 per cent. of potassium oxide. After filtration over silicate, half of the potassium was replaced by calcium and it then contained 0.036 per cent. of lime. On boiling to thick juice at 52° Balling the percentage of lime amounted to 0.13 and juice containing this amount can scarcely be boiled. The replacement of potassium in molasses by calcium or sodium lowers its value to distillers who do not buy it for sugar alone but with a view to utilising the potassium also.—L. J. DE W.

Sucrose; Role of magnesium oxide in the hydrolysis of — at different temperatures. J. Tribot. Compt. rend., 1909, 148, 788—790. (See also this J., 1908, 1125.)

THE author has studied the progress of hydrolysis of sucrose, at temperatures ranging from 25° to 60° C., under the action of crude invertase, of invertase with magnesium oxide, and of invertase purified by twelve successive precipitations. For short periods, the rate of hydrolysis of sucrose by invertase with magnesium oxide begins to become constant at 40° C. whilst with invertase alone, the rate continues to increase up to 60° C. The activity of invertase, purified by successive precipitations, and containing only a trace of mineral matter, though much diminished, is not reduced to zero. At high temperatures, more sucrose is hydrolysed in a given time by the enzyme with magnesium oxide than by the enzyme alone and there is an equivalence between the action of magnesium oxide and the influence of temperature. Hence, magnesium oxide plays the part ascribed to invertase as a whole, and to ferments in general, a part which E. Solvay has described as "thermocatalysis" and which would consist in a lowering of the true temperature of reaction.—L. E.

Starch; The colloidal properties of — in relation to its chemical constitution. E. Fouard. Compt. rend., 1909, 148, 502—504.

PERFECT solutions of starch may be obtained by filtration of the colloid through collodion membranes. If small quantities of potassium hydroxide be added to such true solutions, the specific rotatory power of the dissolved substance is diminished. This diminution depends on the proportion of alkali, and it takes place progressively until a rotatory power of $[\alpha]_D - 141$ is reached, corresponding to that of maltose. The modification produced by the alkali is instantaneous and reversible; the original rotation is restored when the alkalinity is neutralised. If a pseudo-solution of starch be fractionated at different stages of its spontaneous gelatinisation and the fractions

filtered separately through collodion, it is found that the concentrations of dissolved starch decrease as the gelatinisation is more advanced, and that the specific rotatory power of the dissolved substance likewise decreases towards a limit corresponding with the rotatory power of maltose. Both these observations point to the conclusion that the solution of starch, whether by the action of potassium hydroxide or of water, depends on a process of reversible hydrolysis, with maltose as its ultimate term. Starch is therefore simply a condensation product, in a variable and undetermined degree, of maltose. It is a true molecular aggregate of this carbohydrate, aggregation proceeding progressively with elimination of water until the product assumes a colloidal gelatinised state. The changes in the physical state of the colloid are therefore essentially dependent on chemical changes and are consequently in close relation with its constitution.—J. F. B.

Gum tragacanth: Distinction of genuine — from spurious Indian gums. W. L. Scoville. *Drugg. Circ.*, 1909, 53, 116—117.

Two grms. of the gum are shaken with 100 c.c. of water until thoroughly swelled and free from lumps. If in powder, it is first suspended in 3 c.c. of alcohol and poured quickly into the water. Two grms. of borax are then dissolved in the gum solution, and the mixture is allowed to stand over night. Spurious tragacanth then forms a very slimy mucilage, which when drawn out between the finger and thumb, affords long viscous strings. An admixture of 5 per cent. of spurious Indian tragacanth with the genuine gum, under these conditions gives a mucilage which will form strings $\frac{1}{4}$ to $\frac{1}{2}$ inch long when thus manipulated. Genuine tragacanth mucilage shows no such viscosity, and does not acquire a stringy consistence until it has been in contact with borax for several days. Even then, the stringy character is much less marked than is the case with the spurious gum. Indian gum tragacanth mucilage is transparent; acid in reaction; gives no blue colour with iodine solution; does not froth when shaken with an equal volume of 5 per cent. potassium hydroxide solution; and precipitates slowly when mixed with two volumes of alcohol. Mucilage of genuine tragacanth is opaque; neutral in reaction; gives a blue colour with iodine; froths when shaken with 5 per cent. potassium hydroxide solution; and precipitates immediately when mixed with two volumes of alcohol.—J. O. B.

Maize: The maltases of raw —. R. Huerre. *Compt. rend.*, 1909, 148, 505—507.

IN a recent note (this J., 1909, 254), the author showed that the early white and yellow maizes of the Landes contain maltases of different characters, termed respectively "low" and "high" maltases according to the temperatures of their activities. Certain other varieties of maize have now been examined, with the result that they have been found to secrete maltases which may be classed with the two extreme types previously studied, without, however, being actually identical with them. The variety called "Anxonne" secretes a "high" maltase which has no action on maltose at temperatures below 20° C. The other varieties of maize studied, viz., "coarse red," "King Philipp," "Cuezo red" and "white" secrete "low" maltases which hydrolyse maltose readily at 15° C., with differences in the rapidity of their action. These "low" maltases, however, have not the same optimum temperatures of reaction as the "low" maltase of the early white maize of the Landes. The maltase of

"Cuezo red" resembles the "low" maltase of the white maize of the Landes in that it acts upon maltose at 0° C. and is destroyed at 68° C.; but it resembles the "high" maltase of the yellow maize in the fact that the most favourable temperature for its action is about 60° C. The limits of activity of the "King Philipp" maltase are 4° C., minimum, and 60° C., maximum, but its optimum temperature is about 50° C. The author has endeavoured to ascertain whether the different temperature relationships of the various maltases of maize were due to differences in the composition or reaction of the extracts, but these different relationships were always maintained when small quantities of acids, alkalis, or asparagine were added. They are probably, therefore, specific differences, depending on the different origin of the enzymes, unless it be assumed that they depend on the presence of some unknown co-enzyme in greater or smaller proportions.—J. F. B.

Saké yeast: Two Saccharomyces from —. R. Nakazawa. *Zentr. Bakt., u. Parasitenk.*, 1909, II. Abt., 22, 529—540. *Chem. Zentr.*, 1909, 1, 1178.

THE author describes the morphological and biological properties and the conditions of growth of two kinds of *Saccharomyces*, *S. Tokyo* and *S. Yelo*, which he has isolated from saké yeast. In neutral yeast water containing 5 per cent. of sucrose, the two yeasts colour the liquid red and produce a red deposit. They are bottom-fermentation kinds and cause rapid fermentation. Dextrose, sucrose, galactose, and maltose are fermented by them; raffinose is hydrolysed; melibiose and lactose are not attacked.—A. S.

Brewing: The nitrogen question in —. Part II. H. T. Brown. *J. Inst. Brewing*, 1909, 15, 169—284. (See also this J., 1907, 884.)

THE "permanently soluble" nitrogenous constituents of worts and beers may be divided into those which are "assimilable" by yeast and those which are "non-assimilable," and it is only the former class which exerts any influence on the behaviour of the beer. The relation between assimilable and non-assimilable nitrogen may be determined by successive fermentations by yeast in such a manner that reproduction is limited solely by the exhaustion of the assimilable nitrogen. Under fixed conditions of extraction of a given malt, the relation of assimilable to total permanently soluble nitrogen is fairly constant, in which case it is sufficient to study the factors which tend to increase or diminish the latter; under fixed conditions this is in close relation with the initial nitrogen content of the barley. The percentage of the initial barley-nitrogen which is converted and extracted in the form of permanently soluble nitrogen is fairly constant under given conditions. Other things being equal, the increased development of the young plant connotes an increase in both permanently soluble and assimilable nitrogen in the extract from the malt. In the case of an average English malt extracted at 152° F., about 48 per cent. of the permanently soluble nitrogen of the extract is contributed by the germ and 52 per cent. by the endosperm. Of the assimilable nitrogen about 52 per cent. is due to the germ and 48 per cent. to the endosperm. The increased permanently soluble nitrogen of the extracts of "forced" malts is mainly due to the increased mass of the plumule which remains in the malt. Since the weight of the germ amounts to only one-tenth of that of the malt and since it contains about one-half of the assimilable nitrogen, a very great reduction of the latter could be effected, if desired, by de-germing the malt before extraction. Slow drying in the early stages of kilning has practically no effect in increasing the permanently soluble nitrogen of the malt; the final temperature of curing, provided it does not exceed 190° F., also has very little effect. The temperature of mashing has a very powerful influence on the extraction of permanently soluble and assimilable nitrogen. The extraction increases gradually but regularly as the temperature is increased from 60° F. to 100° F. From 100° to 110° F., the extraction of permanently soluble nitrogen increases very rapidly; above 110° F., the increase is slower and reaches a maximum at 120° F., corresponding

with the maximum intensity of the action of the proteolytic ferments. The permanently soluble nitrogen extracted at 120° F. from an English malt amounts to about 40 per cent. of the total nitrogen of the malt, 23 per cent. being pre-existent and 17 per cent. being the product of proteolysis. Above 120° F. the extraction curve falls, and the ordinary mashing temperature of 150° F. marks a critical point at which a degree or two on either side makes a very considerable difference in the permanently soluble nitrogen of the wort. At 180° F. the proteolytic enzymes are inactive and the extraction of permanently soluble nitrogen becomes the same as at 60° F. The curve illustrating the extraction of assimilable nitrogen at different temperatures follows a similar course. When the assimilable nitrogen is classed according to its degree of assimilability, certain well marked changes are noted, depending on the temperature of extraction. When an attempt is made to increase the extract by excessive sparging at high temperatures, a marked increase in the proportion of permanently soluble nitrogen in the extracted matter is noted. Certain mineral salts, e.g. carbonates, restrict the extraction of permanently soluble nitrogen, probably by their influence on the phosphates, and thus on the proteolytic enzymes. Calcium chloride promotes the extraction; the fineness of grinding has no influence. *Hops*.—Boiling with hops in the usual brewing proportions precipitates small quantities of the non-assimilable permanently soluble nitrogen, but the hops contribute an equal amount of assimilable nitrogen to the wort, so that the nett result of the process is to increase the yeast-nutrient to the extent of about 2.5 per cent. of the total nitrogen of the wort. When hops are added to an unboiled wort, their precipitating action on subsequent boiling is confined to the permanently soluble nitrogen. Rather more than one-fourth of the permanently soluble nitrogen is precipitable by an excess of gallotannic acid. Of this precipitated nitrogen about 24 per cent. is readily assimilable, 34 per cent. less readily assimilable and 42 per cent. non-assimilable. *Yeast*.—The relation between the rate of cell-increase and the removal of nitrogen has been carefully studied. For this purpose the number of cells was counted in a unit standard volume of wort ($\frac{1}{47000}$ cub. mm.) and at the same time the nitrogen in the liquid was determined. If a = the nitrogen removed expressed as grms. per 100 c.c., and b = the cell-increase per unit volume, then $a/b = N$ is called the nitrogen coefficient per unit cell. This is practically constant for any given yeast, provided the removal of nitrogen does not exceed 40 per cent. of the total nitrogen of the wort (assimilable nitrogen = about 60 per cent.). Beyond that limit starvation conditions set in and the relation between the two factors is no longer constant. Most commercial top-fermentation yeasts show a nitrogen coefficient of about 0.0020, but in the case of one variety of small-celled yeast it was found as low as 0.0016. *Aeration*.—When a wort contains an excess of the substances requisite for the healthy nutrition of the yeast, the cell-reproduction and removal of nitrogen stand in direct relation to the amount of free oxygen which is available. But even when the last traces of free oxygen are removed there is still a slight reproductive activity, amounting to about 6 cells per unit volume and independent of the quantity of seed yeast, due probably to the presence of some substance which the yeast is able to reduce and utilise in place of free oxygen. In a fully aerated wort the yeast increase and removal of nitrogen have about double the values found for an air-free wort. Up to a degree of about 50 per cent. of full saturation with air, equal increments of free oxygen result in equal increments of cell-increase and nitrogen removal; beyond this point, increased aeration is still effective but not to a proportionate extent. The aerating efficiency of any type of refrigerator may be ascertained by making a blank experiment with boiling water and estimating the dissolved oxygen by Winkler's method: there is no difficulty in obtaining in practice an aeration of 85–100 per cent. saturation. Fully aerated worts, when pitched with yeast in brewing proportions, give up the whole of their free oxygen to the yeast in 2 or 3 hours. The influence of "rousing" in stimulating fermentation is two-fold: it prevents the premature separation of the yeast, promoting

contact between the single cells and fermentable matters, and it favours reproduction of the yeast and the removal of nitrogen by introducing further supplies of air, provided it is conducted in such a manner that the influence of the carbon dioxide is overcome. There are small but appreciable differences in the yeasts of different breweries as regards their power of nitrogen removal from worts when the initial supply of oxygen and other conditions are constant. In ordinary practice the removal of nitrogen from the wort is a function of the free oxygen available and is not influenced by variations in the initial concentration of assimilable nitrogen. Traces of free oxygen in the finished beer exert a marked influence on the subsequent activity of primary and secondary yeasts and their tendency to produce turbidities.—J. F. B.

Wine; Action of iron on —. Trillat. *Compt. rend.*, 1909, 148, 792–795.

THE injurious action of iron on wine has long been recognised: a large proportion of the colouring matter is deposited and the effect of the metal on the odour and flavour of the wine resembles that caused by ageing. The author has found that the proportions of acetaldehyde, ethyl acetate, and acetal are increased when wines are left in contact with metallic iron for several days. The production of aldehyde in wine left in contact with metallic iron or treated with ferric chloride (1 : 5000), is more rapid when the wine is exposed to free air than when the air-supply is limited. The amount of aldehyde produced in wine by contact with metallic iron is alone sufficient to cause precipitation of the colouring matter. The author has also found that the iron is more or less rapidly attacked by the wine according to the degree of purity of the former and the nature of the latter; the action does not, however, always correspond to the degree of acidity of the wine. For a given quantity of iron dissolved in different wines, the appearance of a deposit is accelerated in wines of low alcohol-content and retarded in wines containing much sugar or glycerol. Such deposits, however, may not be due entirely to formation of aldehyde; the oxidising action of the iron on the colouring matter must be taken into consideration. The author concludes that the alteration of wine in contact with iron is due in part to a rapid formation of aldehyde, and the effect of this, in certain cases, explains how a cask of wine may be completely spoiled by the presence of a nail. From the recent researches of de Stoecklin on the oxidising action of iron tannate (see this J., 1909, 111), it may be supposed that the iron is most active in this form.—L. E.

Wines; Coefficient of partition and its application to the determination of the volatile acids of —. P. Malvezin. *Compt. rend.*, 1909, 148, 784–787.

THE author has investigated the partition of some organic acids between ether and water, and between ether and aqueous alcohol at 15° C. He found that under the conditions of his experiments, the acidity acquired by the ether varied with the concentration of the volatile fatty acids (acetic, propionic, butyric) but was independent of the concentration of the fixed acids (tartaric, succinic). On these results, he has based the following method for determining the volatile acids of wines:—Ten c.c. of the wine are thoroughly shaken for 1–2 minutes with 10 c.c. of 65 per cent. (65°) ether in a test-tube (length, 20 cm.; internal diam., 2 cm.). The tube is then closed with a stopper carrying a thermometer, and immersed in water at 15° C. for 10 minutes. The ethereal extract is then decanted and shaken. Five c.c. of the extract are transferred to a flask containing 5 c.c. of 90 per cent. alcohol, the mixture is treated with phenolphthalein (4 drops for a red, 2 drops for a white wine) and titrated with $N/10$ sodium hydroxide. The author has found that under the above-described conditions, 72 per cent. of the volatile acids of a wine are dissolved by 65 per cent. ether. The volatile acidity (expressed as grms. of acetic acid per litre) is found from the formula:

$$(2A - 0.2) \times 0.006 \times 100 \times 100,$$

72

in which A = no. of c.c. of $N/10$ alkali required, and 0.2 is the correction coefficient for this concentration of

alkali. The method is very expeditious, does not involve distillation, and the author has shown that it gives results which agree closely with those obtained by the method of Duclaux.—L. E.

Whisky: Distillation of —. R. M. McDougall, Glasgow. Eng. Pat. 6396, Mar. 23, 1908.

THE process consists in the continuous distillation of whisky possessing all the characteristics and flavour of pot still whisky. The apparatus includes a pot still with a head containing distilling and rectifying plates, the vapour being rectified in one operation. The head, which is surmounted by a water-jacketed conical section, is fitted with cut-out coils and pipes whereby one or more of the rectifying plates may be put out of operation to adjust the strength or flavour of the whisky as desired. The spirit vapour is cooled, first by fresh wash, and then by cold water; the fresh wash, which is supplied continuously, is further heated, before entering the distilling apparatus, by the spent wash and the waste steam from the heating coil in the still.—L. E.

Brewers' wort: Production of —. H. Breker, Cologne, Germany. Eng. Pat. 27,956, Feb. 15, 1908. Addition to Eng. Pat. 25,356, Nov. 15, 1907.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, AND DISINFECTANTS.

(A.)—FOODS.

Raw milk: Coagulation of — by the rennet of the Papaw tree. C. Gerber. Compt. rend., 1909, 148, 497–500.

THE rennet ferment contained in the papayotin prepared from the Papaw tree possesses the same high degree of resistance to the action of high temperatures as the proteolytic ferment of the same plant. This rennet coagulates milk at 0° C. without the necessity of adding calcium chloride, and its action is quite distinct from that of pepsin or Hansen's rennet. The action of papaw rennet generally shows a divergence, depending on the temperature of the reaction, from the law of inverse proportionality between concentration of ferment and time of action. In the case of boiled milk it is easy to obtain slow coagulations, but it was found in the case of raw milk that only rapid coagulations were successful, and these also showed a divergence from the law of Segeleke and Storch in the same sense as the coagulation of boiled milk, the divergence being more pronounced the longer the milk was kept after drawing. It was then found that raw milk when freshly drawn from the cow behaves in an approximately normal manner, and gives slow coagulations almost as readily as boiled milk. The resistance to dilute solutions of the rennet increases, the longer the milk is kept, and at the end of four hours only rapid coagulations can be obtained; the milk then retains this property which it has acquired. The author has proved that the above peculiarity is not due to the fat, the calcium phosphate, nor the salts, but concerns only the colloids, lactalbumin and lactoglobulin. Milk heated to 78° C. behaves in the same manner as boiled milk, and raw milk which has become resistant by keeping, loses this resistance when heated to 75°–78° C.—J. F. B.

Camembert cheese: Proteolytic changes in the ripening of —. A. W. Dox. U.S. Dept. of Agric., Bull. No. 109, 1908.

THE biological factors necessary to the production of Camembert cheese are the lactic acid bacteria, which are normally present in milk, and two moulds, *Penicillium camemberti* Thom and *Oidium lactis*. Other moulds may be present, but they are generally contaminations and often deleterious to the cheese. The actual ripening is caused by the proteolytic enzyme of the mould; this enzyme is secreted by the mould growing on the surface of the cheese and diffuses towards the centre. The digestive action of the enzyme on the paracasein of the cheese produces the true ripening. No appreciable proteolysis occurs until after the cheese is two weeks old, but certain changes take place in the character and solubility of the curd. These changes consist mainly in the liberation of paracasein from combination with calcium, and at the same time the paracasein is converted into a form which is completely soluble in 5 per cent. salt solution; at a later stage it again becomes insoluble. The enzyme appears to be of the nature of erepsin; it attacks casein and peptone readily, but is without action on fibrin and coagulated egg albumin. The following substances have been isolated from Camembert cheese:—caseoglutin, protocaseose, deuterocaseoses A. B. and C, α - and β -peptones, histidine, arginine, lysine, glutamic acid, tyrosine, and leucine, whilst the author failed to find paraneucin, tryptophan, indole, skatole, mercaptan, hydrogen sulphide, and phenols. The ripening of Camembert cheese cannot be due to peptic digestion, as paraneucin, the characteristic product of peptic digestion, is absent, and amino-acids and ammonia are present in considerable amount. Moreover, the greater part of the phosphorus is liberated and appears as acid calcium phosphate; according to Plimmer and Bayliss, pepsin liberates the phosphorus slowly and incompletely, and mostly in the organic form. On the other hand, the ripening resembles ereptic digestion in many respects, as follows:—(1). The acidity of the cheese before the ripening commences is most favourable to the activity of ereptase. (2). The digestion proceeds beyond the peptone stage. (3). A study of the enzyme shows that it is a vegetable ereptase. The absence of tryptophan, which is ordinarily liberated in ereptic digestion, is noteworthy, as is also the presence of caseoglutin, which substance, to the author's knowledge, has not been observed in digestions with pure enzymes.—W. P. S.

Egg albumin: Hydrolysis of — with sodium hydroxide. Z. H. Skrap and F. Hummelberger. Monatsh. Chem., 1909, 30, 125–145.

EGG albumin when hydrolysed with 6 per cent. sodium hydroxide solution is broken up into protalbinic acid, lysalbinic acid and lysalbin-peptone. Protalbinic acid is sparingly soluble in water and dilute acids, lysalbin-peptone is soluble in saturated ammonium sulphate solution. These properties allow protalbinic acid and lysalbin-peptone to be purified, but the lysalbinic acid isolated possibly contains both these substances. On complete hydrolysis the following products are obtained:—

	Original egg albumin.	Protalbinic acid.	Lysalbinic acid.	Lysalbin- peptone.
	per cent.	per cent.	per cent.	per cent.
Histidine.....	1.5	2.3	0.3	0.6
Arginine.....	2.0	0.4	0.2	0.3
Lysine.....	3.0	3.3	5.3	4.0
Tyrosine.....	2.4	3.4	2.6	1.1
Phenylalanine...	5.8	12.0	5.2	2.4
Proline.....	1.5	2.0	1.0	0.3
Amino-acids.....	7.0	14.7	7.0	3.2
Glutamic acid...	3.2	1.8	1.0	1.6

In the case of protalbinic acid, the aromatic products of hydrolysis—tyrosine and phenylalanine—are obtained in larger amounts than from albumin; these amounts

fall further in the case of lysalbinic acid, which has nearly the same composition as albumin, and they fall lowest in the case of peptone. With proline and the amino-acids—leucine, valine, and alanine—similar relations subsist. Protalbinic acid hardly shows any carbohydrate reaction, but lysalbinic acid and particularly the peptone show this more strongly than the original protein. Apparently that part of the protein molecule which is most resistant to sodium hydroxide contains relatively more of the aromatic constituents but lacks the sugar residue. Further this sugar residue forms part of the more resistant portion of the protein molecule and is not a part of the relatively simple peptides which are the first to be eliminated. Protalbinic acid alone yielded hydroxy-protic acid on oxidation with permanganate, indicating that this acid is formed from the more resistant part of the protein molecule. Apparently by the action of sodium hydroxide glutamic acid is more rapidly eliminated from egg albumin than tyrosine, whereas Abderhalden found that tyrosine is the first to be eliminated from edestine and casein on hydrolysis with pancreatic juice.—E. F. A.

Flour and cereals; Alteration of — by sulphur dioxide. M. and G. Careret. Bull. Soc. Chim., 1909, 5, 270—272.

Flour submitted to the action of sulphur dioxide forms a sticky dough from which no gluten is obtained on washing in the usual manner. Flour made from wheat which has been treated with sulphur dioxide, forms a sticky dough very difficult to knead, which will not ferment with yeast and gives very close bread unfit for consumption. The sulphur dioxide destroys the elasticity of the gluten; in the dough it causes the destruction of gluten into its constituents rather than its solution in the weak acid liquid.—E. F. A.

Tea; Contribution to the knowledge of —. C. Hartwich and P. A. Du Pasquier. Apoth.-Zeit., 1909, 24, 109—110, 119—121, 130—131, 136—137. Chem. Zentr., 1909, 1, 1182—1183.

For the microchemical detection of caffeine in the different portions of the tea-leaf, the authors make use of the formation of the double compound of the alkaloid hydrochloride and gold chloride, the leaves being immersed first in water to remove the tannin, and then in a mixture of hydrochloric acid and gold chloride. The results so obtained corresponded with the results of analytical determinations of the alkaloid by Keller's method. In 19 kinds of tea the caffeine content ranged from 1.78 to 4.21, average 3.95 per cent. Young leaves from Pallanza, Italy, contained 3.7; old leaves, 1.35 per cent. of caffeine. With a good commercial tea, the youngest leaves contained 9.2 per cent. of caffeine, and then with increasing size of the leaves, the percentage of caffeine fell to 3.9, 3.6, and 0.8 respectively. The wood of the stem of the plant contained 0.06; the bark, 0.08; the wood of the root, 0; and the root-bark, 0.15 per cent., of caffeine. In blossoms from Pallanza, the calyx contained 2.39, the petals, 0.44, and the whole buds, 2.09 per cent. In two kinds of Cochin-China tea consisting entirely of dried flower buds, 1.17 and 1.25 per cent. of tannin respectively was found. In tea seeds, 0.059 per cent. was found in the husk and 0.097 and 0.107 per cent. in the cotyledons. The tannin of tea reduces Fehling's solution. The chief proportion of the caffeine is liberated during the withering and rolling operations, the quantity being increased only by about 3 per cent. during the fermentation process. During the roasting the amount diminishes by about 14 per cent. The tannin liberated from the caffeine-tannin compound during the withering and rolling operations, yields phlobaphene on fermentation. Analyses of a number of rare kinds of tea are given in the original.—A. S.

Cocoa industry of Bahia. Board of Trade J., April 1, 1909. [T.R.]

THE total output of cocoa from the State of Bahia during the 1907-8 season amounted to about 27,000 metric tons; the average yield of each mature cocoa tree, per season, may be taken to be 2½ kilos. of dried beans; the number of cocoa trees planted per hectare may be

taken to average 625. Hence the total area under cocoa cultivation in the State at the present time amounts to some 16,000 hectares (40,000 acres), and that there exist some 10,000,000 cocoa trees in bearing.

Three varieties of cocoa are grown in Bahia, differing in the size and shape of their pods, and in the texture of the rind. In the matter of the average yield per tree, and of quality of bean, there would seem to be little to choose between the three varieties. The yield per tree, in the case of mature trees, is taken to average 2½ to 3 kilos. of dried beans annually. That this average could be substantially increased by the bestowal of a little intelligent care upon the trees admits of no doubt, since the product of one carefully cultivated plantation averages over 6 kilos. of dried beans per tree per season, and on an estate in the Belmonte district there are trees that have yielded 15 kilos. of dried beans during a season.

Experiments have been carried out in Bahia during the past few years in connection with the drying of cocoa by artificial heat. It has been found that the oven system dries the beans more thoroughly than does exposure to the sun, and that the product fetches higher prices in the Bahia market than does the sun-dried article, by reason of its superior and more regular colour. The system, however, has been adopted to only a very limited extent, owing to the cost. At the present time there are not more than a dozen such stoves at work.

Brazil, as a whole, furnishes at the present time something over one-fifth of the world's supply of cocoa. Of that proportion the State of Bahia contributes over 80 per cent. The output of cocoa in the State of Bahia has increased from 14,000 metric tons in 1901-2 to 25,182 metric tons in 1907-8, and 27,000 metric tons (estimated) in 1908-9.

There is every reason to believe that this rate of increase will be maintained in the future. The area of land in the State suitable for the cultivation of cocoa is practically unlimited, and the conditions existing there are favourable for the growth of the cocoa tree. On the other hand, the planters are heavily handicapped by lack of transport facilities, there being no railway in the cocoa-producing area, whilst the roads are very bad, and the rivers inconvenient.

The exports of cocoa from Bahia in 1907 were as follows:—United States of America, 6,402,463 kilos., Germany, 6,167,180 kilos., France, 4,778,732 kilos., United Kingdom, 2,373,225 kilos., and 1,290,168 kilos. to other countries.

Food product, and process of making same. A. Behr, Pasadena, Cal. U.S. Pat. 914,379, Mar. 9, 1909.

THE food product, consisting principally of nitrogen-phosphorus compounds, is obtained by steeping corn (maize) in hot water, rendering the liquid alkaline, and separating the precipitate formed.—W. P. S.

Milk; Apparatus for concentrating —. E. E. Claussen, Hartford, Conn. U.S. Pat. 915,019, Mar. 9, 1909.

THE apparatus consists of a number of receptacles placed side by side and each surrounded by a hot-water jacket. Each succeeding receptacle is of smaller capacity than the one preceding it. The milk to be concentrated is introduced into the first receptacle of the series, and jets of compressed air, entering through pipes at the bottom of the receptacle, are passed through it, a perforated screen being placed across the receptacle in order to break up the air bubbles. The milk then flows through a channel at the top of the receptacle into the next of the series, where it is also subjected to jets of air, and so on.—W. P. S.

Albumen; Process for drying —. P. A. Schmitt and O. Ahrens, Hamburg, Germany. Eng. Pat. 14,256, July 4, 1908.

SEE Ger. Pat. 201,680 of 1907; this J., 1908, 1172.—T.F.B.

(B).—SANITATION; WATER PURIFICATION.

Water; Storage of raw river — antecedent to filtration. A. C. Houston. Report to Metr. Water Board, 1909, 1—47.

THE report deals with the systematic observations, including chemical and bacteriological investigations, which were carried out during the twelve months ending July 31st, 1908, on the effect of storage on raw river water. As regards the advantages of storage, it is pointed out that adequately stored water is probably incapable of causing epidemic disease, and the author is in favour of storage *plus* filtration. It has been shown previously (see this J., 1908, 873) that typhoid bacilli perish rapidly when added to raw river water, and it may be inferred that a still more marked reduction, if not total elimination, of the less hardy and less numerous microbes of water-borne disease takes place. The recorded results of the experimental part of the investigation show that storage reduces the number of bacteria of all sorts and devitalises the microbes of water-borne disease (e.g., the typhoid bacillus and the cholera vibrio); it also reduces the amount of suspended matter, colour, ammoniacal nitrogen, hardness, and oxygen absorbed from permanganate; the quantity of albuminoid nitrogen in the water may be reduced, or its quality altered, by storage. It was found that storage tends generally to lengthen the life of the filters and has a marked "levelling" effect on the quality of water delivered to the filter beds. The use of stored water enables a constant check to be maintained on the safety of London's water antecedent to and irrespective of filtration, and renders any accidental breakdown in the filtering arrangements much less serious than would otherwise be the case. The author concludes, finally, that raw river water should be stored before filtration, preferably for 30 days. This period of storage would, possibly, have to be subject to the qualification that provision must be made for times of flood or drought when river water could not be admitted to the storage reservoirs.

The report also deals with the shape, size, depth, construction, and method of working storage reservoirs; alternative measures (sterilisation being the only one, and this would be impracticable on account of expense); and the disadvantages of storage. All the real or assumed disadvantages of storage disappear if the use of stored water be regarded as an elastic policy which can be departed from on occasions when the local conditions render this feasible and at the same time desirable.—W. P. S.

PATENT.

Water; Process for purifying —. C. W. Schultze, Assignor to H. K. Perry, Buffalo, N.Y. U.S. Pat. 944,887, Mar. 9, 1909.

WATERS containing calcium salts are purified by the addition of definite proportions of aluminium sulphate, kaolin, and starch. The gelatinous precipitate which forms enmeshes the bacteria and suspended matters, as well as dissolved organic substances, in the water, and the whole precipitate is then removed by passing the water through fibrous material.—W. P. S.

(C).—DISINFECTANTS.

Basic cuprous chloride (cuprous oxychloride). M. Deletrez, L'Engrais, March 26, 1909.

THE action of copper salts in the treatment of the cryptogamic diseases of plants has long been known, but it has been more recently proved that if instead of using copper sulphate according to the old methods, cuprous oxychloride, produced preferably by the electrolytic method (this J., 1907, 987), be substituted, then both economy and efficiency are gained, for this green powder remains for a long time in suspension when mixed with water, and adheres with great tenacity to the leaves and fibres of plants. For spraying vines, for the destruction of mildew, the oxychloride is used in aqueous suspension, in which 200 to 250 grms. are contained in 100 litres of water, the weight of metallic copper represented being approximately 125 grms., as compared with 2 kilos. of copper sulphate

in 100 litres of water, and containing 500 grms. of metallic copper, which would have been required for the same purpose.

PATENT.

Terpineol preparations [disinfectants]; Process for obtaining water-soluble —. F. Fritzsche und Co. Ger. Pat. 207,576, Jan. 24, 1906.

A QUANTITY of terpineol greater than that required merely to impart a perfume to the product, is added to ordinary soaps, with the exception of the so-called "Derizin soaps." Contrary to the view generally held, it has been found that sufficient quantities of terpineol for disinfecting purposes can be mixed with soaps, without any addition of alcohol, glycerin, etc., and without the necessity of using a special kind of soap.—A. S.

XIX.—PAPER, PASTEBOARD, &c.

Pulp logs; Loss of wood in trimming —. B. Smärt. Papier Zeit., 1909, 34, 923—924.

LOGS intended for pulping are roughly trimmed in the forest and are subsequently cleaned and freed from residual bark in the mill. This latter operation may be performed either by hand or machine; hand trimming wastes less wood, but costs more in labour. Thick logs suffer less loss, in proportion, than slender logs. The loss of wood in the barking operation may be determined either by measuring or by weight, the latter method being preferable. The results actually obtained must be corrected so as to show the loss of real wood as distinct from the bark proper; they must also be calculated on the dry substance. A fresh spruce log contains 25—30 per cent. of moisture in its heart-wood and 60—70 per cent. in the outer rings. As the result of storage this relation may change, and the outer portions become drier than the centre, or else as the result of rain they may become still wetter than before. The extent of the preliminary removal of the bark, the season of felling, and the length of storage all influence the relative proportions of moisture in the outer and inner layers. In the following table results obtained in the hand trimming of logs of different sizes, which had been felled in the winter, only roughly trimmed in the forest, and stored for a year, are given.

Diameter of logs.	Dry substance.		Total loss of dry substance.	Weight of true bark.	Loss of wood with bark.	
	In the wood.	In the bark.			On original log.	On trimmed log.
cm.	per cent.	per cent.	per cent.	per cent.	per cent.	per cent.

Sulphite wood pulp; The rosin-content of — and its effect in paper-making. E. Ahlfors and H. Helin. Papier-Fabrikant, 1909, 7, 287—289.

ROSIN specks in paper may be due either to the size used, or to the presence of resinous impurities in the sulphite wood pulp. The pale French rosins, when used for making size are particularly liable to form sticky deposits, owing to the fact that, in order to preserve their pale colour, the distillation of the turpentine is not carried so far as in the case of dark varieties of rosin. The possibility of rosin specks is greater the higher the proportion of free rosin in the size. According to Dalén, rosin specks due to this size, give off the characteristic odour of rosin when touched with a hot needle; they are also more readily soluble in

ether or alcohol than rosin specks derived from the wood pulp. The latter are generally larger, more irregular, and darker than size specks, and they generally occur in combination with calcium sulphate or sulphite. In the case of a resinous pulp, the rosin gradually agglomerates in the beating engines, stuff-chests, and paper machine to form lumps which, when carried forward in the paper, are deposited, and according to circumstances, cause tearing or puncture of the paper at the couch-roll, stoppage of the wires, sticking at the press-rolls, finally appearing as specks in the paper. Pulp which contains much rosin presents the peculiarity of requiring far more beating than clean pulp of a similar degree of boiling. Sometimes it is necessary to give the resinous pulp double the usual time of beating, with the result that the wearing qualities of the paper suffer. The treatment during the boiling of the wood, has no particular influence on the rosin-content of the pulp; provided the treatment is sufficient to dissolve the lignin, it is also sufficient to decompose the polyterpenes which exist in combination with the rosin. But if the pulp and the digestion liquor be allowed to cool in presence of each other after boiling, the rosin is re-deposited on the fibres and is not readily removed by washing. In order to obtain a clean pulp, the liquor should be drained off the pulp as hot as possible, and the stuff should then be washed with hot water. It is possible to eliminate the terpenes by steaming the wood, previous to boiling, for several hours at a sufficiently high temperature, and removing the condensed water. If the wood be stored for several months after felling, a considerable portion of the turpentine exudes, whilst the remainder is converted into a less objectionable form. Finally, an advantage may be derived by treating the pulp in the breakers or separators with a hydrocarbon, which dissolves the rosin and carries it away with the wash-waters. Certain pulp-makers trace a connection between an excess of lime in the digestion liquors, or the use of weak digestion liquors, and a resinous product.—J. F. B.

Tapioca and palm starches for paper-making. F. Virneisel. Papier-Fabrikant, 1909, 7, 335—338.

In Germany, potato starch is the variety generally used for paper making, on account of its lower price as compared with the cereal starches which find favour in England. As substitutes, the author has investigated two starches from German East Africa, viz., tapioca starch and the starch from a species of palm, *Tacca pinnatifida* Forst. African tapioca starch has a pale yellow colour; considering the crude methods employed in its refining, it is remarkably free from residues of the cellular tissue of the plant, consequently it should present no difficulty in manufacture. Contrary to Wiesner's observations, the sample of tapioca starch examined, contained only a minority (about 33 per cent.) of twin granules or their components, the majority being of fairly regular spherical form. The dimensions ranged from 5 to 35 μ , the most common size being 18—20 μ , thus resembling maize and wheat starches. The hilum is generally distinct, being stellate in the larger granules; no stratification is visible. Gelatinisation begins at 55° C., and is complete at 64° C. The starch of *Tacca pinnatifida* had a yellowish colour, and was perfectly free from tissue residues. Its microscopic appearance closely resembles that of tapioca starch, with the exception that a larger proportion of the granules are or have been aggregates, and a smaller proportion of spherical granules are present. The limiting dimensions are the same as for tapioca starch, but with a tendency to a higher average. Gelatinisation takes place between 55° and 68° C. These African starches occupy an intermediate position between potato starch and the cereal starches such as wheat and maize. Their pastes, whether made with hot water or with caustic alkali, are likewise intermediate in character between the compact, stiff-setting pastes of potato-starch and the more fluid, slimy pastes of the cereal starches. In alkaline solution the tapioca starch has a darker colour than the *tacca* starch. These starches are considerably cheaper than the cereal starches, and are already employed outside Germany for textile finishes; there is no reason why they should not find a place in the paper industry.—J. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, & EXTRACTS.

Quinine in cinchona bark; Determination of —. W. Duncan. Pharm. J., 1909, 82, 429—430.

THE author finds that if 10 grms. of sodium sulphate be dissolved in 100 c.c. of a solution containing 0.1 gm. of anhydrous quinine sulphate, and the whole kept for 24 hours at a temperature not above 3° C., the quinine sulphate is precipitated practically quantitatively. At higher temperatures the separation of the alkaloid is less complete; at 12° C., under otherwise similar conditions, 0.0051 gm. remains dissolved. Under the same conditions and even at greater concentrations, the sulphates of quinidine, cinchonine, and cinchonidine remain dissolved. In making use of this difference for the determination of quinine in cinchona bark, the sulphuric acid solution of the total alkaloids is exactly neutralised with sodium hydroxide solution and 10 grms. of sodium sulphate added per 100 c.c. of solution. After 24 hours, the quinine sulphate is filtered off, and either washed with water saturated with quinine sulphate, dried, and weighed; or, preferably, washed with a small quantity of 10 per cent. sodium sulphate solution, dissolved in alcohol, and titrated with N/20 alcoholic sodium hydroxide solution, using phenolphthalein as indicator.—A. S.

Aconite root and preparations; Modification of the U.S. Pharmacopœia method for alkaloidal valuation of —. H. Bernegau. Amer. J. Pharm., 1909, 81, 122.

TWELVE grms. of powdered aconite root are shaken occasionally for four hours with 100 c.c. of ether, 21 c.c. of chloroform, and 12 to 15 c.c. of saturated sodium bicarbonate solution. An aliquot part of the ethereal solution (say 60 c.c.=6 grms. of drug) is then filtered off, and shaken in succession with 50, 40, and 30 c.c. of 1 per cent. sulphuric acid solution. Without waiting for complete separation of the emulsion, the aqueous portions with the emulsified layer are run off and mixed in another separator; on shaking these, almost complete separation takes place at once. The clear liquid is drawn off, and the remaining emulsion and froth is washed with another 30 or 40 c.c. of 1 per cent. sulphuric acid solution, the separated liquid being mixed with the other acid liquid. The determination of the alkaloid is then continued as directed in the U.S.P., using cochineal as indicator in the titration.—J. O. B.

Alkaloidal extracts; Deterioration of — by keeping [due to presence of moisture]. H. Ribaut. Bull. Sci. pharm., 1908, 15, 495—503. J. Fricotel, *ibid.*, 687—691.

RIBAUT has observed a marked loss in total alkaloids in a series of extracts from solanaceous plants, kept for 4 years. This loss varied in different batches of the same extract; in the case of extract of belladonna herb, it was from 3 to 45 per cent. of the total alkaloids. Belladonna root extract lost from 1 to 12 per cent.; henbane herb extract, 69 per cent.; henbane seed extract, from 19 to 24 per cent., and stramonium extract, from 8 to 31 per cent.

Fricotel has determined monthly the alkaloidal loss in a series of extracts for a period of 8 months: the extracts experimented with being belladonna herb and root, henbane herb and seed, stramonium, hemlock, aconite, and opium. The results confirm those of Ribaut. It is found, however, that when these extracts are dried, they all retain their alkaloids practically unaltered during a period of 6 months. Dried extracts of alkaloidal drugs should, therefore, replace the soft, moist extracts at present used in pharmacy.—J. O. B.

Aloes from Sicily. G. Conde-Vissichio. Arch. Pharm., 1909, 247, 81–95.

THE author has examined a species of aloes indigenous to Sicily (*Aloë vulgaris* Lamarek). The drug prepared from the sap contains a large proportion of aloin (sicaloin), together with a small amount of emodin. Sicaloin, $C_{15}H_{10}O_7$, is a white crystalline powder, which forms colourless solutions with ethyl or methyl alcohol, acetic acid, or pyridine, and pale yellow solutions with alkalis, or hydrochloric acid. It contains one methoxyl grouping. Its properties differ from those of other aloins previously described.—F. SHDN.

Viburnum nudum; Fruit of —. R. H. Lott. Chem. News, 1909, 99, 169–171.

FROM the dried fruits of the shrub, *Viburnum nudum*, which is common in swampy regions from the New England States to Florida, the author has extracted two sugars, probably dextrose and levulose, and an oil related to olive oil (present in the kernel). The percentage of total sugar in the fruits was 42.85. Albumin, citric and tartaric acids, and a little malic acid were also found. Analysis of the ash showed: silica 2.11 per cent., alumina 3.88, ferric oxide 3.88, calcium oxide 7.66, magnesia 1.87, potassium oxide 12.87, sodium oxide 16.79, sulphur trioxide 27.14, and phosphoric oxide 12.89.—F. SHDN.

"Stachyose" in white jasmine (Jasminum officinale, L.). J. Vintilescu. J. Pharm. Chim., 1909, 29, 336–339.

THE twigs of white jasmine, gathered in December, were extracted with boiling water in the presence of excess of chalk. The filtrate was evaporated under reduced pressure, and the residue extracted with alcohol to remove mannitol. The substance remaining was dissolved in water, alcohol added, and the liquid filtered. The filtrate was treated with lead acetate, filtered, and the excess of lead removed. Barium hydroxide was added, followed by the addition of alcohol, which caused a precipitate. The precipitate was removed, dissolved in water, and the barium removed by means of carbon dioxide. The filtrate was evaporated and the residue crystallised from alcohol. The substance thus obtained melts at 100°C . in a capillary tube. It dissolves in water, and does not reduce Fehling's solution till after boiling with a mineral acid. In aqueous solution it has $[\alpha]_D^{20} = +132.2^{\circ}$ to $+132.98^{\circ}$. It is oxidised to mucic acid by nitric acid. The molecular weight is 630. It agrees in its properties with the stachyose, $C_{24}H_{42}O_{21}$, of Schulze and von Planta (see Tanret, this J., 1903, 888).—F. SHDN.

Calcium citrate and lemon juice; New method of analysis of —. L. and J. Gadais. Bull. Soc. Chim., 1909, 5, 287–289.

TWENTY grams of calcium citrate are boiled with 20 c.c. of distilled water and 25 c.c. of hydrochloric acid, the solution is cooled, made up to 250 c.c. and filtered. 25 c.c. of the filtrate are placed in a porcelain crucible, and treated with $N/1$ potassium hydroxide until a drop of phenolphthalein is just coloured rose; a few drops of $N/1$ hydrochloric acid are then added and 1 c.c. of saturated calcium chloride solution. The liquid is concentrated to 25 c.c. and filtered whilst hot, the crystalline precipitate being washed on to the filter and washed several times with boiling water before being dried at 105°C . The calcium citrate adhering to the crucible and stirrer is dissolved in 4 drops of $N/1$ hydrochloric acid, the main filtrate added, the liquid neutralised with ammonia, and concentrated to 15 c.c. It is again filtered whilst hot, and the precipitate collected, washed, and dried as before.

The process is repeated a third time. The dry precipitates are united in a platinum crucible and calcined: the colourless ash is transferred to a porcelain dish and the crucible washed out with 30 c.c. of $N/1$ hydrochloric acid to dissolve the remaining carbonate and this acid used to dissolve the rest. The liquid is boiled to expel carbon dioxide, and the excess of acid neutralised with $N/1$ potassium hydroxide. In analysing lemon juice, 120 c.c. are made up to 1000 c.c., 25 c.c. are taken, neutralised, 20 c.c. of calcium chloride added and the process carried out as above.—E. F. A.

Turpentine (pinene); An aldehyde from —. C. Harries and H. v. Splawa-Neyman. Ber., 1909, 42, 879–880.

PINENE obtained by distillation from French turpentine oil was dissolved in glacial acetic acid and treated with ozone. The solution was heated on the water-bath and fractionated. The fraction boiling between 100° and 140°C . at 12 mm. reduced Fehling's solution. It yielded a disemicarbazone, $C_{12}H_{22}N_4O_2$, melting at 214° – 215°C . Probably pinonic aldehyde was produced by the action of ozone upon pinene.—F. SHDN.

Camphor exports from Formosa. Board of Trade J., April 15, 1909. [T.R.]

THE exports of camphor from Formosa in 1908 showed a falling-off of about 33 per cent. as compared with 1907. The distribution of the export for the two years was as follows:—

	1907.	1908.
To—	lb.	lb.
Hong-Kong, ultimate destination Europe	1,304,933	561,600
United Kingdom	548,000	460,000
India via Hong-Kong	—	4,000
France	—	278,666
Germany	—	53,333
United States	588,900	870,400
Japan	—	536,734
Transhipped at Kobe—		
To United States	1,046,400	—
" India	33,333	—
Total	4,121,566	2,764,733

THE total export to Europe in 1908 was 1,353,599 lb., as against 2,452,933 lb. in 1907, a decrease of 1,099,334 lb. The serious decrease in the export of camphor is due chiefly to the competition of synthetic camphor and the increased export from China, assisted by the low price of silver in the latter country.

Borneol, camphor, and isoborneol; Action of potassium hydroxide on —. Racemic campholic acid. M. Guerbert. Compt. rend., 1909, 148, 720–723.

THE author has previously shown that when *d*- or *l*-borneol is heated at 250° – 280°C . with potassium hydroxide, most of the substance is converted into the corresponding campholic acid. It is now found that camphor is present in the products of the reaction: this transformation of borneol into camphor implies a loss of hydrogen, whilst camphor can combine with nascent hydrogen to form borneol. There is therefore formed an equilibrium mixture of the two and this explains the simultaneous presence of camphor and borneol in all the author's experiments. The yield of campholic acid in the above reaction becomes almost theoretical when camphor is heated with twice its weight of anhydrous potassium hydroxide in a sealed tube at 280° – 290°C . Isoborneol, heated under the same conditions, furnishes an inactive campholic acid identical with the racemic acid resulting from a mixture of the *d*- and *l*-acids. *r*-Campholic acid crystallises in transparent hexagonal tablets, melting at 109° . 100 parts of alcohol dissolve 19.8 parts of the acid at 80°C . The sodium salt has the formula, $C_{15}H_{17}O_2Na \cdot 8H_2O$; the anhydride, $(C_{15}H_{17}O_2)_2O$, melts at 66°C . and the amide at 90°C .—J. C. C.

d-Limonene nitrosochloride and a new carvoxime.
E. Deussen and A. Hahn. Z. Riech- u. Geschmacksstoffe, 1909, 1, 25–26.

THE nitrosochloride of *d*-limonene was treated with sodium methoxide to convert it into carvoxime. The crystals of *l*-carvoxime (m. pt. 72° C.) which separated were removed, and the remaining oil benzoylated. The product was crystallised from light petroleum, when a benzoylcarvoxime was obtained, which melted at 77° C. after crystallising from dilute alcohol, and which had $[\alpha]_D^{20} = +75.3^\circ$ in benzene. On hydrolysing with alcoholic potassium hydroxide, *d*-carvoxime, $C_{10}H_{14}NOH$, was produced. This crystallises from dilute alcohol in glistening needles melting at 57°–58° C., and has $[\alpha]_D^{20} = +68.3^\circ$ in benzene. The author proposes the name α -carvoxime for the *l*-carvoxime of m. pt. 72° C., and the name β -carvoxime for the new carvoxime described above.

—F. SHDN.

Essential oils; Constituents of —. *Enolisation of camphenilanaldehyde. Production of terpinolene by the inversion of carvenene.* F. W. Semmler. Ber., 1909, 42, 962–966.

By treating camphenilanaldehyde with acetic anhydride and sodium acetate, *enol*-camphenilanaldehyde acetate, $C_{15}H_{18}O_2$, is produced. This substance boils at 113°–116° C. at 10 mm., and has the sp. gr. 1.0125 at 20° C., and $n_D^{20} = 1.4816$. On oxidation with ozone, camphenone is produced. When the *enol*-acetate is reduced with sodium and alcohol, camphenyl alcohol, $C_{10}H_{16}O$, is produced, which boils at 105°–106° C. at 10 mm., and melts at 58°–59° C. It is also produced by reduction of the aldehyde. Camphenilanaldehyde must therefore possess a labile hydrogen atom in close proximity to the aldehyde grouping. The “terpinene” produced from sabinene mono- or dihydrochloride is found to contain small amounts of terpinolene, when tested with bromine in amyl alcohol. Carvenene prepared from carvenone contains no terpinolene. When inverted to *iso*-carvenene by means of alcohol and sulphuric acid (this J., 1909, 258), a small amount of terpinolene is formed at the same time.

—F. SHDN.

Ylang-ylang oil. Chem. and Drug., 1909, 74, 534.

THE production of ylang-ylang oil in the Philippines has increased enormously in recent years, the exports (including packages, which amount perhaps to nineteenth of the whole) in the period 1904–7 being 10,917, 13,395, 27,909, and 27,036 kilos, respectively. The industry is carried on mainly in Manila, but also in the provinces of Mindoro, Albay, and the Camarines. The provincial distillers are at an advantage compared with those in Manila, in that they get their flowers cheaper and of better quality, but as the provincials are not so careful in distilling, their oil is generally inferior. In the distillation of the first grade of oil, the only points requiring special attention are that the distillation be conducted slowly, with clean steam, and that not more than 1 kilo. of oil be collected from 400 kilos. of flowers. Any further oil obtained should be kept separate and sold as second class. The distillation-apparatus should be lined with block tin or nickel throughout. Twenty-three samples of first-grade oil and sixteen samples of the second-grade product gave the following results:—

	First-grade oil (23 samples).	Second-grade oil (16 samples).
Specific gravity (30–34° C.)	0.827 to 0.949	0.896 to 0.940
Optical rotation	$[\alpha]_D^{20} = -26^\circ$ to -49.7°	-27.7° to -87.0°
Refractive index (at 30° C. for D line)	1.4747 to 1.4940	1.4838 to 1.5082
Ester value	95 to 129.7	49 to 94

These results all indicate that an oil with a low refractive index, low rotation, and high ester value, is certain to be good. Distillation experiments conducted *in vacuo* showed that of a first-grade oil 50 per cent. will pass over below 100° under 10 mm. pressure. The common adulterants of Philippine ylang-ylang oil are said to be alcohol,

turpentine oil, and coconut and other fixed oils. Samples of a highly refined turpentine oil are said to be prepared for the use of ylang-ylang distillers, who are stated to sprinkle it on the flowers before distillation. Turpentine oil is best detected by distilling 100 c.c. of the oil under 10 mm. pressure, when not more than 1 c.c. should come over below 65° C. Pinene is readily found in such a low-boiling fraction by the usual methods. Alcohol and coconut oil can be detected by the ordinary tests. (See also this J., 1908, 875.)

Cinnamic acids; The isomeric —. E. Billmann. Ber., 1909, 42, 182–188.

THE author points out that there are three isomeric cinnamic acids: Liebermann's isocinnamic acid, m.pt. 57° C.; Erlenmeyer, sen.'s isocinnamic acid, m.pt. 38°–46° C.; Liebermann's allocinnamic acid, m.pt. 68° C. The author considers that these three acids constitute a case of trimorphism. One isomeride may be readily converted into the other if precautions are taken to exclude all traces of the other acids during the experiments. If a tube containing allocinnamic acid is closed by a cotton-wool plug, heated in a steam-oven to 100° C., and cooled in ice, it solidifies and will then melt at 41° C. (Erlenmeyer's acid). If the acid melting at 41° C. is heated to 44° C., and a trace of the acid of m.pt. 58° C. added, it at once solidifies, and then consists of Liebermann's isocinnamic acid, m.pt. 58° C. This can be converted into allocinnamic acid by heating to 64° C. and adding a crystal of allocinnamic acid. Similar results are obtained when these acids are crystallised from light petroleum.

—F. SHDN.

Allo- and isocinnamic acids. C. Liebermann. Ber., 1909, 42, 1027–1036.

THE author confirms the results of the experiments by Billmann (see preceding abstract) on the isomeric cinnamic acids. He finds that both the isocinnamic acids (m. pts., 42° C. and 58° C.) can be converted into allocinnamic acid by certain mechanical and chemical means, such as rubbing in a mortar. Contrary to Billmann, the author finds that when allocinnamic acid is crystallised from light petroleum, isocinnamic acid, m.pt. 58° C., is only occasionally, instead of always, obtained. The acids are stable by themselves over the following temperature intervals; acid melting at 42° C. from 0 to 120° C.; allocinnamic acid up to 80° C., and the acid melting at 58° C. up to 70° C.—F. SHDN.

Mutual solubility effect of aqueous solutions of ether, chloroform, phenol, etc. H. Fühner. Ber., 1909, 42, 887–889.

WHEN saturated aqueous solutions of ether and chloroform are mixed, a turbidity is produced, and, on allowing the mixture to stand, drops containing ether and chloroform separate out and the solution becomes clear. This observation is of importance in pharmacology as it may explain why a mixture of ether and chloroform has a more pronounced action than the components. Further, concentrated aqueous solutions of other substances have been examined, phenol and chloroform solutions remain clear when mixed, but phenol and ether solutions give a turbidity. Benzene solutions mix clearly with those of ether, chloroform, and phenol, and solutions of light petroleum, carbon bisulphide, and ethyl chloride behave similarly. Amyl alcohol solution remains clear with chloroform or ether solutions but gives a milky turbidity with phenol solution. Ethyl acetate solution mixes clearly with ether solution, but gives a turbidity with chloroform or phenol solutions.—J. C. C.

Mercuric oxycyanide. E. Rupp and S. Goy. Arch. Pharm., 1909, 247, 100–107.

WHEN a solution of mercuric cyanide is treated with potassium iodide, the following reaction takes place: $2Hg(CN)_2 + 2KI = Hg(CN)_2.HgI_2.2KCN$. The solution of the triple salt thus formed has an alkaline reaction to litmus and gives up half of its hydrocyanic acid when treated with acids. When excess of potassium iodide is added, mercuric-potassium iodide and potassium

cyanide are produced: $\text{Hg}(\text{CN})_2 + \text{HgI}_2 + 2\text{KCN} + 6\text{KI} = 2(\text{HgI}_2 \cdot 2\text{KI}) + 4\text{KCN}$. When the resulting solution is concentrated, crystals of the triple salt separate. The reaction between mercuric oxycyanide and potassium iodide varies according to the amount of the latter substance present. With an insufficient amount of the iodide, the reaction takes place as follows:— $\text{HgO} \cdot \text{Hg}(\text{CN})_2 + 2\text{KI} + \text{H}_2\text{O} = \text{HgI}_2 + \text{Hg}(\text{CN})_2 + 2\text{KOH}$. With a sufficiency of the iodide, the reaction can be represented:—

When excess of potassium iodide is present, the result is as follows:—

The "glistening crystals" formed when a saturated solution of mercuric oxycyanide is treated with potassium iodide (Holdermann's reaction), consist of mercuric iodide. Towards iodine, mercuric oxycyanide behaves as a mixture of mercuric oxide and cyanide. Similar results are obtained with bromine and chlorine. When mercuric oxycyanide is treated with hydrochloric acid, the double salt of mercuric chloride and cyanide is produced. A similar reaction takes place when hydrobromic acid is used in place of hydrochloric acid. When hydriodic acid is used, mercuric iodide and free hydrocyanic acid are produced.—F. SHDN.

Determining alkali iodides. Rupp and Penning.

PATENTS.

Pancreas preparation suitable for the treatment of diabetes; Manufacture of a —. A. Zimmermann, London. From Chem. Fabr. auf Aktien, vorm. E. Schering, Berlin. Eng. Pat. 8514, April 16, 1908.

The pancreas of a narcotised animal is laid bare, preferably when digestion is at its height, and the veins of the pancreas ligatured to produce stasis. The pancreas is removed after a time, allowed to digest for 24 hours, the albuminous bodies precipitated by alcohol and the filtrate evaporated in a vacuum. The preparation so obtained is a fine, grey, feebly smelling powder, easily soluble in water and dilute soda solution.—F. SHDN.

Mercury compound (mercuric p-aminophenylarsonate); New — and method of manufacturing the same. May and Baker, Ltd., and A. G. Bates, London. Eng. Pat. 8959, April 24, 1908.

MERCURIC salts and salts of p-aminophenylarsonic acid can be made to interact to form mercuric p-aminophenylarsonate. This compound is insoluble in water. It forms with halogen derivatives of alkali metals or metals of the alkaline-earths, compounds which are soluble in water and do not coagulate albumin.—F. SHDN.

p-Aminophenylarsinic acid; Mercury salt of —. W. Grüttemann, Vohwinkel, Germany. Assignor to Farbenfabriken vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pat. 914,408, Mar. 9, 1909.

THE salt is obtained by the action of mercuric chloride on p-aminophenylarsinic acid; it is a white powder, almost insoluble in water, and insoluble in alcohol or ether. Yellow mercuric hydroxide is precipitated when the salt is treated with sodium hydroxide.—W. P. S.

Iron salts; Manufacture of therapeutically valuable —. C. Sorger, Frankfurt on Main, Germany. Eng. Pat. 23,330, Nov. 2, 1908.

THE alkali salts of phosphoric and tartaric acids, phosphoric and citric acids, arsenic and tartaric acids, or arsenic and citric acids, are treated with soluble iron salts. The formation of the new salts may also be brought about by the addition of a given amount of tartaric or citric acid to iron phosphate or arsenate; or by addition of phosphoric or arsenic acid to iron tartrate or citrate.—F. SHDN.

Ortho-dioxyphenylalkamines; Manufacture of optically active —. Farbwerke vorm. Meister, Lucius, und Brüning. Eng. Pat. 3021, Feb. 8, 1909. Under Int. Conv., July 31, 1908.

SYNTHETIC racemic o-dihydroxyphenylalkamines, such as synthetic suprarenine, for instance, can be resolved into their optically active isomerides by treatment of their tartrates. d-Suprarenine obtained in this way is identical with the natural product. (See this J., 1909, 107.)

—F. SHDN.

Phenoxydialkylaminopropanols and their acyl derivatives; Production of —. Etah, Poulenc Frères and E. Fournéau. Fr. Pat. 395,470, Dec. 28, 1907.

SECONDARY amines are allowed to act upon phenylglycidic ether, or phenoxychloropropanol, when combination between the two takes place with the formation of a phenoxydialkylaminopropanol. The substance may then be treated so as to esterify the alcoholic hydroxyl grouping.—F. SHDN.

Aldehydes; Process of making —. C. Ellis, White Plains, N.Y., and K. P. McElroy, Washington, D.C. U.S. Pat. 915,946, March 23, 1909.

FORMALDEHYDE can be made by exposing a metallic formate to a regulated heat in the presence of a current of gas of regulated composition, which carries away the formaldehyde. The formaldehyde thus formed can be recovered by condensation. The formate can be brought to the point where it is heated in a thin, continuous travelling layer. Other aldehydes can be produced in a similar manner.—F. SHDN.

"Blackboy"; Industrial utilisation of the tree commonly known in Australia as —. R. W. Wallace and G. Reynaud. First Addition, dated Dec. 24, 1907, to Fr. Pat. 394,234, Nov. 20, 1907. (See this J., 1909, 255.)

THE bark and other portions of trees of the *Xanthorrhoea* (Blackboy, Grass-tree, etc.) are ground and treated with water. The woody portions float to the surface and can be removed, whilst the resinous portions settle to the bottom in a compact mass. The resin contains sugar which can be used to form alcohol, which in its turn can be used to extract the gum-resins. Substances such as camphor and benzoin can be obtained from trees of this type by steam-distillation.—F. SHDN.

Camphene and isobornyl esters from pinene hydrochloride; Process for preparing —. G. Wendt. Ger. Pat. 207,888, June 23, 1908.

SOLID pinene hydrochloride (2 parts), glacial acetic acid (4 parts), and glacial phosphoric acid (1 part) are heated under a reflux condenser, at 150° C., for one hour, when a further quantity of phosphoric acid (1 part) is added. After 14 to 24 hours, all the hydrochloric acid will have been separated. The resulting isobornyl acetate always contains camphene in solution; the product can be now saponified and oxidised to camphene or "hydratised." Other organic acids may be employed in place of acetic acid, or the process may be carried out by means of phosphoric acid alone.—T. F. B.

Amides of higher fatty acids; Process for the manufacture of —. O. A. H. H. Kösters, Hemelingen, and L. Ottmann, Bremen, Germany. U.S. Pat. 915,680, March 16, 1909.

SEE Eng. Pat. 6731 of 1907; this J., 1907, 637.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Chromated gelatin films; Electrical method for measuring the changes produced in — on exposure to the light. H. Mayer. Z. physik. Chem., 1909, 66, 33–70.

THE films were produced by pouring on to carefully cleaned glass plates a solution of 4 grms. of soft emulsion-gelatin and 0.5 gm. of potassium bichromate in 96 grms.

of water, and the changes produced on exposure to light were followed by measurements of the electric conductivity. It was found that on exposure to light the conductivity of the gelatin decreased; for the normal time of exposure (1 hour) this decrease amounted to several per cent. of the original conductivity. The percentage alteration of the conductivity was independent of the initial conductivity of the film (before exposure). The conductivity of the chromated gelatin increased rapidly with rising temperature, but the temperature coefficients for the films before and after exposure were different. Comparative measurements of the conductivity must always be made under identical conditions with respect to the humidity of the surrounding atmosphere, as variations in this had a considerable effect on the conductivity. The sensitiveness to light of chromated gelatin, as measured by the percentage alteration of its conductivity decreased with increase of the age of the film, at first rapidly and then more and more gradually. The changes in conductivity produced on exposure to light continued for a certain time on subsequently keeping the film in the dark.

—A. S.

XXII.—EXPLOSIVES, MATCHES, &c.

Guncotton and nitroglycerin; Improvements in production and application of—F. L. Nathan. Royal Institution, Jan. 29, 1909. (See this J. 1908, 193; 1909, 177.)

IN this communication, British Service powder cordite was described, with its preparation, mode of testing, etc. Cordite originally consisted of nitroglycerin, 58 parts; guncotton (insoluble in nitroglycerin), 37 parts; and mineral jelly, a product of the distillation of crude petroleum, 5 parts. To effect the gelatinisation of the guncotton, acetone is employed. A nitroglycerin powder is more powerful than a nitrocellulose powder, and the more nitroglycerin present the more powerful the explosive. Therefore, for equal ballistics, a smaller charge of the former than of the latter is required, and, consequently, the chamber capacity and the size and weight of the breech mechanism are reduced; on the other hand, the higher the proportion of nitroglycerin the higher is the temperature of combustion, and the greater the erosive effects on the surface of the bore of the gun. The presence of nitroglycerin in an explosive allows of the more easy and rapid elimination of the solvent used in manufacture, and of moisture, a small quantity of which is always present in nitroglycerin and guncotton. Nitroglycerin powders are cheaper than nitrocellulose powders, weight for weight, and even more so for equal ballistic effects. The original cordite, the manufacture of which commenced in 1890, contained a high proportion of nitroglycerin (58 per cent.), and the erosion produced, especially in large guns, was considerable. In 1901, a modified cordite known as "cordite M.D.," consisting of nitroglycerin, 30 per cent., guncotton, 65 per cent.; and mineral jelly, 5 per cent., was introduced. The constants of explosion of cordite and cordite M.D., determined at the Royal Gunpowder Factory, are as follows:—

Explosive.	Density of loading.	Heat of explosion at constant volume, water gaseous.	Total gases, water gaseous at 0° C., and 760 mm.	Temperature of explosion.
		Calories per grm.	cc. per grm.	°C.
Cordite	0.2	1156	871	2663
Cordite M.D.	0.2	965	920	2374

This shows a decrease in the heat of explosion of about $16\frac{1}{2}$ per cent. and an increase in the volume of gases of about $5\frac{1}{2}$ per cent., whilst there is a decrease of 289° C. in the temperature of explosion. As would therefore be expected the erosion produced by cordite M.D. is very much less than that produced by the original cordite for the same ballistics, and is certainly not greater, if as great, as that produced by the best forms of nitrocellulose

explosives. Although of minor importance to smokelessness, flamelessness is a desirable quality for propulsive explosives to possess. In this respect cordite M.D. is superior to cordite in the case of rifles and machine guns. A suitable ingredient has not yet been discovered which will render smokeless powders flameless in large guns. A third ingredient in both kinds of cordite, viz., mineral jelly, although present in a comparatively small proportion, is a very important constituent. Cordite, in the advanced experimental stage, consisted of nitroglycerin and guncotton alone, and as their combustion produced no solid residue of any kind, the surface of the bore of the magazine rifle in which the early experiments took place was not fouled in any way. The result was that the cupro-nickel coated bullets, propelled in succession at high velocity through a clean barrel, deposited some of the cupro-nickel in the bore. In order to prevent this a number of substances were incorporated with the nitroglycerin and guncotton, with the object of producing a deposit in the bore, which it was hoped would get rid of the difficulty of metallic fouling. Of all these various substances the one which appeared to answer the purpose most satisfactorily was refined vaseline, and this material became the third ingredient of cordite, as eventually introduced into the British Service. When the manufacture was commenced on a large scale, vaseline was replaced by mineral jelly, the same material, but in a cruder form. The original object with which mineral jelly was introduced was of no importance when cordite was substituted for the black and brown powders used in large guns, but in order to have but one kind of smokeless powder in the service, mineral jelly was added to all cordite whether for use in small arms or artillery. Subsequent experience has demonstrated how very fortunate was the selection of this material for rifle cordite and the extension of its use to all sizes of cordite. Mineral jelly is one of the best ingredients it is possible to have in smokeless powders from the point of view of their chemical stability. This important fact, not recognised originally, was brought out in the following way: In order to facilitate the explosion of cordite in blank ammunition for the rifle, it was cut into very thin flakes and the non-explosive mineral jelly was omitted from its composition. After a comparatively short storage in a hot climate, the stability of the smokeless blank, as it was called, was found to have suffered seriously, whereas the stability of normal cordite containing mineral jelly was not appreciably affected. These facts led to a thorough investigation at Waltham Abbey, of the action of mineral jelly in preserving the stability of cordite, and it was discovered that mineral jelly contained constituents which had the valuable property of combining with the decomposition products (the result of prolonged storage of cordite at high temperatures) to form stable bodies, thus removing these decomposition products, which undoubtedly exert a deteriorating influence on the cordite, from their sphere of action. Smokeless powders are all subject to deterioration, and there is very little doubt that this deterioration is for any given explosive a function of the temperature of storage. The higher the temperature, the more rapid the deterioration. The necessity therefore of some quantitative test which would enable a judgment to be formed as to the extent of deterioration suffered by any given sample of cordite is obviously of great importance, because such a test would afford the means of determining how much longer it would be safe to store any given batch of cartridges or lot of cordite at any given temperature. Any such test must be a heating test, and it must be possible to co-relate the temperature and duration of the test with any given temperature and duration of storage. The rate of deterioration as a function of the temperature was determined by Will for guncotton, and later by Robertson at Waltham Abbey for nitroglycerin. From these and other experiments carried out at Waltham Abbey, a factor of increase in rate of deterioration of cordite with increase of temperature was deduced. This factor having been determined, what is known as the "silvered vessel test" was worked out at the Royal Gunpowder Factory. In this test, cordite is heated in a specially designed vessel at 80° C., a temperature not too far removed from those to be met with when cordite is stored under the

worst service conditions, and the number of hours' heating at this temperature any given sample will stand before it shows signs of active decomposition are ascertained. Then, by means of an equation, containing the factor connecting rate of increase of deterioration with rise in temperature, a calculation can be made converting the hours of heating at 80° C. the sample withstood, to years and fractions of a year it would stand at any given temperature of storage, and therefore a knowledge is obtained of how much longer it would be safe to store this cordite at any given temperature. This test was applied to a considerable number of samples of known age and thermal history. From these data and knowing the number of hours at 80° C. that newly-made cordite of good stability will stand before showing signs of decomposition, the number of hours that the different samples should stand the test were calculated. When the samples were actually tested, the number of hours heating at 80° C. they withstood, were in close agreement with the number of hours it was calculated they should stand. The form of vessel in which the heating is carried out is the well-known vacuum vessel of Dewar. A glass bulb, silvered externally, is enclosed in an outer bulb, silvered internally. The space between the two is highly evacuated for the purpose of limiting the dissipation of any heat evolved by exothermic changes on the one hand, and on the other for the purpose of minimising the effect of accidental slight changes in temperature of environment. In the centre of the inner bulb is situated the bulb of a thermometer, the stem of which passes through a cork in the neck of the vessel. A side tube is attached for the purpose of making observations on the colour of the gases evolved. For heating the vessel, a bath is provided, with cylinders closed at the bottom, and wide enough to admit the vessel to such a depth as the side tube will permit. The bath is surrounded by insulating materials. The vessels are packed in the cylinders with wool yarn, and the tops of the cylinders are closed with felt discs, to exclude draughts. The bath is fitted with a gas regulator or other means for securing that the temperature of the explosive is kept constant. The cordite is coarsely ground, and 50 grms. are used. Readings of the thermometer are taken at intervals, and the time is noted when a rise of 2° C. in the temperature of the explosive above the temperature of 80° C. occurs. At the same time, visual observations are made as to the colour of the column of gas in the side tube, since it is found that previous to the rise in temperature occurring, orange-coloured fumes of nitric peroxide are evolved. When the temperature exceeds 82° C., the test is complete and the flask is withdrawn. The number of hours which have elapsed since the start of the test is the measure of the stability of the cordite.—G. W. McD.

Committee to investigate the Abel heat test for explosives.
Times, April 27, 1909. [T.R.]

THE Home Secretary has appointed a departmental committee to investigate and report on the best means of standardizing with greater accuracy than at present the apparatus and materials employed in the Abel heat test for explosives, and to examine and report on any supplementary test or tests that may be submitted.

The committee is constituted as follows:—Major A. Cooper-Key (Chairman); Colonel Sir Frederic L. Nathan; Captain A. P. H. Desborough; Mr. F. W. Jones; Captain M. B. Lloyd; Mr. C. O. Lundholm; Major J. H. Mansell, R.A. The secretary of the committee is Major H. Coningham, R.A., to whom correspondence may be addressed at the Home Office.

PATENT.

Explosives; Manufacture of — R. Escales and M. Nowak, Munich, Germany. U.S. Pat. 915,165, March 16, 1909.

SEE Eng. Pat. 21,117 of 1907; this J., 1908, 91.—T. F. B.

XXIII.—ANALYTICAL CHEMISTRY.

INORGANIC—QUANTITATIVE.

Nickel coins; Analysis of — W. J. Van Heteren and H. Van der Waerden. Chem. Weekblad, 1909, 6, 157–165. Chem. Zentr., 1909, 1, 1115.

THE usual method for the analysis of nickel-copper alloys consists in dissolving in nitric acid, separating the copper electrolytically, removing nitric acid from the solution by evaporating with sulphuric acid, adding ammonia and ammonium sulphate, and then separating the nickel electrolytically. The authors find that if a mixture of sulphuric acid with a relatively small proportion of nitric acid (for example, a mixture of 15 c.c. of nitric acid of sp. gr. 1.3, 25 c.c. of sulphuric acid of sp. gr. 1.8, and 40 c.c. of water) be used to dissolve the alloy, the troublesome evaporation with sulphuric acid may be dispensed with, the small quantity of nitric acid left in the solution being without any injurious effect on the electro-deposition of the nickel.—A. S.

Antimony; Determination of — E. G. Beckett. Inaug. Dissertation, Zürich, 1909.

THE author's work comprised a study of the methods for the determination of antimony iodometrically and as trisulphide, tetroxide, and pentoxide, and of the separation of antimony from tin. It was found that gravimetrically antimony can be determined most accurately as trisulphide by the method of Henz (Z. anorg. Chem., 1903, 37, 1) or that of Vortman and Metzl (this J., 1905, 943). Antimony trisulphide precipitated from hydrochloric acid solution always contains chlorine. When dried at 110° C., the red sulphide contains about 1 per cent., and the gray sulphide about 0.5 per cent. of chlorine; on heating in a current of carbon dioxide at 300° C., the major portion of the chlorine is evolved in the form of hydrochloric acid, from 0.15 to 0.3 per cent. remaining behind in the residue, a quantity not sufficient to appreciably influence the accuracy of the results. Antimony sulphide can be obtained quite free from chlorine by heating it to its melting point in a current of hydrogen sulphide. Antimony can be determined accurately as tetroxide if the precipitate be ignited at 800°–900° C. in an electric furnace; at 1000° C., the tetroxide is appreciably volatile. Antimony cannot be determined satisfactorily as pentoxide. The iodometric process yields results comparable with those obtained by the trisulphide method only when the atomic weight of antimony is taken as 122; if the atomic weight 120.2 be used, the results obtained iodometrically are always about 1 per cent. lower than those given by the trisulphide method. The author used pure antimony trisulphide as standard substance in his experiments. For the separation of antimony from tin, Vortman and Metzl's method (*loc. cit.*) is not so good as Henz's modification of Clarke's process (this J., 1904, 133).—A. S.

Sulphates and fluorides; Separation of — R. Ehrenfeld and A. Indra. Chem.-Zeit., 1909, 41, 375–376.

THE substance is mixed in a Rose crucible with ten times its bulk of zinc dust, the mixture is covered with a layer of zinc dust and then heated for half an hour over a strong burner in a stream of hydrogen or purified coal gas. After cooling, the mixture is brought into a flask and a few grams of a mixture of precipitated silica and finely ground alumina added to combine with the hydrofluoric acid. Dilute sulphuric acid is then run in and the resulting sulphuretted hydrogen passed into N/10 iodine, the last traces of the gas being driven out by boiling and by a stream of carbon dioxide. Excess of N/10 thiosulphate is then added and the excess titrated back with N/10 iodine.—H. P. P.

Alkali iodides; Acidimetric determination of — E. Rupp and F. Pfennig. Arch. Pharm., 1909, 247, 108–110.

THE fact that a solution of mercuric cyanide becomes alkaline on the addition of potassium iodide can be used

to determine the amount of iodine present in an iodide by the following method. 1—2 grms. of mercuric cyanide are dissolved in 30—50 c.c. of water in a 100 c.c. flask, and 0.5—1.5 gm. of the iodide added, with a milligram or so of potassium chloride to aid the precipitation. This is followed by the addition of 25 c.c. of $N/2$ hydrochloric or sulphuric acid. The volume of the liquid is made up to 100 c.c., the liquid filtered, and the excess of acid in 50 c.c. of the filtrate determined by titration, using methyl orange as indicator. 1 c.c. of $N/2$ acid corresponds to 0.0635 gm. of iodine as iodide. The accuracy of the reaction is not interfered with by the presence of chlorides, but bromides prevent a sharp colour change with the indicator.—F. SHDN.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Radium rays; Chemical action of — on water. M. Kernbaum. Compt. rend., 1909, 148, 705—706.

The author allowed the rays emitted from radium to pass through thin glass, an air space, and then into a vessel containing water. In this way the action of the α -rays was eliminated. After a month the gas produced was found to consist of almost pure hydrogen, the corresponding amount of oxygen being found in the water in the form of hydrogen peroxide.—J. C. C.

Oxydases of *Russula delica*; Some new properties of the —. J. Wolff. Compt. rend., 1909, 148, 500—502.

The author has examined the oxydasic enzymes of certain vegetable extracts, particularly the glycerol extracts of *Russula delica*. When acting upon tyrosine and many other substances which respond to their oxidising action, these enzymes exhibit their maximum activity when the medium is approximately neutral to phenolphthalein, whereas malt amylase acts most powerfully in a medium which is neutral to methyl orange. When the neutral point to phenolphthalein is passed in one direction or the other, the oxydasic reactions only take place with great difficulty, particularly on the acid side. The oxydases of *Russula delica* possess the property of oxidising a large number of colouring matters, such as sulphonated alizarin derivatives, cochineal, hæmatoxylin, quinoline blue, Poirrier's orange I., and several colouring matters contained in flowers. Poirrier's orange II., magenta and its derivatives, and methyl orange are not oxidised. Some of these substances are oxidised with equal facility by laccase, e.g., hæmatoxylin and quinoline blue, others are more resistant towards laccase, whilst the soluble derivatives of alizarin, cochineal, and the colouring matters of flowers are not oxidised at all by laccase. If cochineal be decolorised by the *Russula* oxydase and the solution be boiled, the colour is regenerated. The regenerated cochineal is precipitated by uranium acetate in the form of a green lake, whereas the decolorised solution is unaffected by the uranium salt. It is assumed that the *Russula* extract contains a reducing substance which

regenerates the oxidised cochineal colour. If the *Russula* extract be heated to 65° C. it loses its property of oxidising tyrosine, but it is still capable of oxidising the colouring matters mentioned above. The difference between the oxydase of *Russula* and laccase may depend on the presence of a special co-enzyme in the *Russula* extract, but if this be so, the co-enzyme does not resist boiling, since a boiled extract does not render laccase capable of acting on the colouring matters which resist it.—J. F. B.

Hordeum vulgare [barley]; Selective permeability of the coverings of seeds of —. A. J. Brown. Proc. Roy. Soc., 1909, B 81, 82—93.

The results of further experiments (see this J., 1908, 134) show that the selective power of the coverings of the barley corn is confined to the testa and probably to that portion of it which is derived from the epidermis of the nucellus during the development of the seed. The power of the seed contents of attracting water from a saturated solution of sodium chloride slightly exceeds the osmotic attraction of the latter. Experiments with volume-normal and weight-normal solutions of sodium and potassium chlorides and nitrates, copper sulphate, sulphuric acid, tartaric acid, and sucrose show that although the various solutes appear to regulate the diffusion of water into the seeds in a very similar manner, minor differences are always observable. Mercuric chloride and cyanide, which are only slightly dissociated in aqueous solution, diffuse readily into the seeds, but after several days no trace of mercuric salt can be detected in those placed in solutions of mercuric nitrate or sulphate, which are highly dissociated. Similar differences are observed with the slightly dissociated cadmium iodide and the somewhat more highly dissociated chloride and sulphate. Acetic, formic, propionic, and butyric acids pass freely, together with water, into the seeds from their aqueous solutions; the entry of glycolic and lactic acids takes place far more gradually. Trichloro-acetic acid rapidly enters the seeds and is the only strong electrolyte capable of so doing. When the corns are immersed in $N/2$ or $N/4$ ammonia solution, water diffuses into them more rapidly than when water alone is used, ammonia passing in at the same time. Water is absorbed by the seeds from solutions of alcohol, aldehyde, acetone, and ethyl acetate approximately as it is absorbed from acetic acid solution or when the seeds are in contact with water alone; in the anhydrous condition, these substances do not diffuse through the seed-coverings, although they do so readily from their aqueous solutions. Glycerol and glycine produce considerable diminution in the proportion of water absorbed and the same is the case, though to a less extent, with urea and ethyleneglycol. The author suggests that the variations in behaviour exhibited by solutions of different substances may be due to differences in the manner of combination of the solutes with the solvent water.—T. H. P.

Trade Report.

Chemical industry of Norway. Chem.-Zeit., March 30, 1909.

THERE are seven carbide factories in Norway, with a total horse-power of 57,000, and capable of producing 80,000 to 90,000 tons of carbide annually. The export of carbide amounted to 22,600 tons in 1907, and 36,666 tons in 1908. The price fell 15 per cent. during the year, and the increase in the number and size of factories, not only in Norway, but in Italy, France, and Switzerland, makes a further fall probable, as the world's consumption is estimated at no more than 180,000 tons. The manufacture of ferro-silicon is completely suspended on account of the over-production which followed the success of this industry in 1907, when 4,000 tons, valued at £50,000, was exported. The manufacture of superphosphate progresses favourably, and one of the two large concerns manufacturing this article has largely increased its sulphuric acid plant. Several companies are now actively engaged in working up low-grade phosphates into precipitate. The cellulose industry did well in the early part of the year, but during the latter half, production was

reduced 30 per cent. all round by arrangement to meet the falling price. Little good was secured by this measure, however, as the Swedish factories failed to fall into line. The condensed milk industry continues to advance, one large company having increased its output nearly 50 per cent. in the year. The export of iron ore shows a slight set back, and one considerable undertaking has suspended operations. The export of high-grade titaniferous ores, containing up to 40 per cent. of titanic acid, has reached considerable dimensions. The single large cement works was destroyed by fire in May, and thereafter the national demand for cement, some 280,000 barrels per annum, was met by Danish supplies. The factory has, however, been rebuilt and enlarged, and expects to render further imports superfluous. The prospects of the industry are not considered very bright, having regard to the general European over-production of cement.

Mineral production of Germany in 1908. Board of Trade J. April 15, 1909.

THE following are the principal items of the mineral production of Germany in 1908, as compared with the preceding year:

	1907.		1908.	
	Quantity.	Value.	Quantity.	Value.
	Metric tons.	1000 marks.	Metric tons.	1000 marks.

New Books.

JAHRBERICHT ÜBER DIE LEISTUNGEN DER CHEMISCHEN TECHNOLOGIE MIT BESONDERER BERÜCKSICHTIGUNGEN DER ELEKTROCHEMIE UND GEWERBESTATISTIK FÜR DAS JAHR 1908. Bearbeitet von Dr. FERDINAND FISCHER, Professor an der Universität in Göttingen. I. Abteilung: Anorganischer Teil. Otto Wigand, Verlagsbuchhandlung m.b.H., Leipzig. 1909. Price, M.15.

Svo volume, containing 619 pages of subject matter with 256 illustrations, and indexes of authors and subject matter, and also a tabulated list of German patents. The subjects treated of are grouped as follows:—I. Wood, peat, coal and coke. II. Petroleum, paraffin. III. Illuminating gas. IV. Acetylene. V. Water gas. VI. Generator gas, etc. VII. Matches and match compositions. EXTRACTION OF METALS AND METALLURGY. VIII. Iron. IX. Manganese, nickel, chromium, tungsten. X. Copper. XI. Gold. XII. Silver and lead. XIII. Zinc, etc. XIV. Alloys. XV. Metallic coatings. CHEMICAL MANUFACTURE. XVI. Sulphur, sulphurous acid, sulphuric acid. XVII. Ammonia. XVIII. Potash industry. XIX. Sodium chloride and soda. XX. Electrolytic alkali and chlorine. XXI. Chlorine, bromine, and iodine. XXII. Nitric acid, nitrate. XXIII. Explosives. XXIV. Phosphates, artificial manures, etc. XXV. Carbides, nitrides, and silicides. XXVI. Metallic compounds, etc. XXVII. Oxygen and hydrogen. XXVIII. Water. XXIX. Glass: clays, cements; lime. XXX. Earthen-ware. XXXI. Portland cement, slag cements, etc. XXXII. Lime, lime-sandstone, and gypsum. XXXIII. Apparatus. XXXIV. New Books. XXXV. Statistics.

LABORATORY GUIDE OF INDUSTRIAL CHEMISTRY. By ALLEN ROGERS, Ph.D., Instructor in Industrial Chemistry, Pratt Institute, Brooklyn, etc. Archibald Constable and Co., Ltd., 10, Orange Street, Leicester Square, London, W.C. 1908. Price 6s. net.

Svo volume, containing 154 pages of subject matter, and an alphabetical index; also 11 blank pages for memoranda. There are 24 illustrations. The subjects treated of are grouped as follows:—I. General processes. II. Inorganic preparations. III. Dyeing of textile fibres. IV. Commercial organic compounds, coal-tar colours, and synthetic oils. V. Pigments and lakes. VI. Driers, varnishes, paints, and stains. VII. Soap, and allied products. VIII. Leather manufacture. IX. Wood fibre, pulp, and paper. X. Useful data.

THE MANURING OF HOPS. By BERNARD DYER, D.Sc. Vinton and Co., Ltd., 9, New Bridge Street, Ludgate Circus, London, E.C. Price 1s.

PAMPHLET, containing 13 pages of subject-matter, and two sheets of photographic illustrations of crops, under the various manurial conditions. Here are brought up to date, the results of the continuous hop manuring experiments carried on by Mr. Shrivell and the author at Golden Green, Hadlow, Tonbridge, showing the average of the results of thirteen seasons, together with detailed results of the crops of 1907 and 1908.

MODERN ORGANIC CHEMISTRY. (Contemporary Science Series.) By CHARLES ALEX. KEANE, D.Sc., Ph.D., Principal and Head of the Chemistry Department, The Sir John Cass Technical Institute, London. The Walter Scott Publishing Co., Ltd., London and Felling-on-Tyne. 1909. Price 6s. net.

Svo volume, containing 488 pages of subject matter, with twenty-nine illustrations, and an alphabetical index. The subject matter is sub-divided and classified according to the following scheme:—I. Historical development of organic chemistry. II. The structure of organic compounds. III. Classification of organic compounds. IV. The aliphatic hydrocarbons. V. The cyclic hydrocarbons. VI. Melting point and boiling point of organic compounds. VII. The sources of the hydrocarbons. VIII. Hydrocarbon derivatives. IX. Ethereal salts. X. Derivatives of the hydrocarbons containing nitrogen.

XI. The laboratory methods of organic chemistry. XII. Stereochemistry. XIII. The sugars. XIV. Isomeric change and dynamic isomerism. XV. Heterocyclic and polycyclic compounds. XVI. Synthesis of physiologically active organic compounds.

THE CHEMISTRY AND LITERATURE OF BERYLLIUM. By CHAS. L. PARSONS, B.S., Professor of Inorganic Chemistry in New Hampshire College. The Chemical Publishing Co., Easton, Pa. 1909. Price \$2.00. Williams and Norgate, 14, Henrietta Street, Covent Garden, London, W.C.

8vo volume, containing 168 pages of subject matter, with a valuable bibliographic list of works on beryllium (pages 72-168), and indexes of authors and subjects. The subject matter is classified as follows:—I. Discovery and history. Preparation from beryl. II. Metallic beryllium. III. Normal compounds of beryllium. IV. Acid salts. V. Double salts. VI. Basic compounds.

Patent List.

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of Application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

7769. Walker. Driers for rotary kilns. April 1.
8180. Pearce. Cleaning or removing suspended matter from gaseous media. April 5.
8260. Cowper-Coles. Consumption of smoke. April 6.
8299. Dewhurst. Furnaces. [U.S. Appl., April 7, 1908.]* April 6.
8469. Richardson. Evaporating tanks or vessels for acid, liquors, &c. April 8.
8481. Blakeley. Apparatus for washing, cooling, and heating gases or liquids. April 8.
8541. Boulton (Bradley). Drying apparatus. [Comprised in No. 25,299 of 1908.]* April 8.

COMPLETE SPECIFICATIONS ACCEPTED.

- 2479 (1908). Nichols. Separation of the liquid and solid components of wet slimes or ore pulp. April 15.
7613 (1908). Brougham (Preyss). Raising the temperature of substances containing bodies sensitive to change, especially physiologico-chemical substances. April 15.
9384 (1908). Kirkham, Hulett, and Chandler, Ltd., and Hersey. See under II.
14,674 (1908). Featherstone. Filters. April 7.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

7470. Stern. Apparatus for use in producing gas.* March 29.
7780. Duff, and Gas Power and By-Products Co., Ltd. Gas producers.* April 1.
8150 and 8151. Senftner. Electrodes for arc lamps. Ger. Appls., April 14 and Dec. 17, 1908.]* April 5.
8229. Dempster and Sons, Ltd., and others. Manufacture of gas. April 6.

8399 and 8400. Jones. Coke ovens. [Additions to No. 11,660 of 1906.]* April 7.

8476. Dempster and Sons, Ltd., and others. Gas retorts. April 8.

8558. Parker. Destructive distillation of coal. April 8.

COMPLETE SPECIFICATIONS ACCEPTED.

- 4266 (1908). Parker. See under III.
8014 (1908). Lynn. Plant for recovering ammonia from producer gas. April 15.
9384 (1908). Kirkham, Hulett, and Chandler, Ltd., and Hersey. Filters, chiefly for use in purifying gas. April 7.
9891 (1908). Thiernich. Generating coal gas for operating internal combustion engines. April 15.
26,027 (1908). A.-G. f. Kohlendestillation. Recovery of ammonia from gases produced in dry distillation. April 7.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

APPLICATIONS.

8026. Eldred. Increasing the efficiency of illuminating oils. April 3.
8558. Parker. See under II.

COMPLETE SPECIFICATIONS ACCEPTED.

- 4266 (1908). Parker. Apparatus for the destructive distillation of coal and other carbonaceous substances. April 7.
26,027 (1908). Act.-Ges. f. Kohlendestillation. See under II.

IV.—COLOURING MATTERS AND DYESTUFFS.

APPLICATIONS.

7819. Newton (Bayer und Co.). Manufacture of vat dyestuffs. April 1.
7820. Newton (Bayer und Co.). Manufacture of acid wool dyestuffs. April 1.
7821. Newton (Bayer und Co.). Manufacture of azo dyestuffs. April 1.
7905. Act.-Ges. f. Anilinfabr. Manufacture of a secondary disazo dyestuff. [Ger. Appl., April 4, 1908.]* April 2.
7931. Johnson (Badische Anilin und Soda Fabrik). Manufacture of colouring matters of the anthracene series. April 2.
8144. Newton (Bayer und Co.). Manufacture of trisazo dyestuffs. April 5.
8154. Cassella und Co. Manufacture of red, chromable dyestuffs. [Fr. Appl., April 7, 1908.]* April 5.
8416. Newton (Bayer und Co.). Manufacture of disazo dyestuffs. April 7.
8438. Dreyfus, Tompkins, and Clayton Aniline Co. Manufacture of halogenated compounds of indigo and indigoid bodies. April 7.
8677. Bloxam (Act.-Ges. f. Anilinfabr.). Manufacture of sulphurised dyestuffs. April 10.

COMPLETE SPECIFICATIONS ACCEPTED.

- 7575 (1908). Newton (Bayer und Co.). Manufacture of condensation products from 1-8-naphthylenediamine. April 7.
27,747 (1908). Inray (Soc. Chem. Ind. in. Basle). Manufacture of brominated indigos. April 7.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

APPLICATIONS.

7538. Calico Printers' Association, and Ashton. Production of certain effects in calico printing. March 30.
7617. Friedrich. Production of a substance for use in making artificial threads, &c. (Ger. Appl., March 30, 1908. Addition to No. 4104 of 1909.)* March 30.

7650. Calico Printers' Association, and others. Production of ornamental effects on textile fabrics. March 31.

7731. Ransford (Cassella and Co.). Production of print effects on fabrics. March 31.

7743. Wetter (Knoll and Co.). Treating acetylcellulose to enhance its elasticity and its power of absorbing dye-stuffs. [Addition to No. 24,284 of 1907.]* March 31.

7881. Young. Continuous open bleaching process and machine therefor. April 2.

8079. Green. Cleaning, preparing, and dyeing textile fibres and fabrics, and materials therefor. April 5.

8270. Niblett. *See under XVIII C.*

8331. Huillard. Treatment of fabrics.* April 6.

8600. Mayo. Extraction of grease and similar matter from and treatment of wool-skins, textile and other materials. April 8.

COMPLETE SPECIFICATIONS ACCEPTED.

8726. (1908). Johnson (Badische Anilin und Soda Fabrik). Discharge of colouring matters of the thio-indigo and indigo classes. April 7.

11,834 (1908). Schneider. Treatment of animal fibres, yarn, or fabrics to modify their shrinking properties. April 7.

14,593 (1908). Johnson (Badische Anilin und Soda Fabrik). Production of green, olive, and brown effects in dyeing and printing. April 15.

17,653 (1908). Frazer. Bleaching or boiling kiers for linen or cotton piece goods or yarns. April 15.

21,829 (1908). Gminder. Treatment of fabrics in spread-out form with liquids. April 15.

2522 (1909). Johnson (Badische Anilin und Soda Fabrik). *See under XIV.*

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

7452. Fabry. *See under II.*

7495. Chem. Werke vorm. H. Byk. Manufacture of solid durable perborate preparations. (Ger. Appl., April 14, 1908.)* March 29.

7507. Serpek. Production of aluminium nitride. March 29.

7633. Jaubert. Manufacture of salts derived from alkaline, alkaline earth, or earthy peroxides. (Fr. Appl., April 29, 1908.)* March 30.

7720. Lévy. Production of substances by means of chlorine. March 31.

7849. Clark (Dellwik-Fleischer Wassergas-Ges.). Production of hydrogen. April 1.

8469. Richardson. *See under I.*

8555. Dolphin. Manufacture of copper and other metallic sulphates. April 8.

COMPLETE SPECIFICATIONS ACCEPTED.

6888 (1908). Troeller. Extracting, in the shape of oxides, sulphites, and sulphates, zinc and other metals from ores and products. April 7.

6919 (1908). Arndts. Manufacture of durable solutions of hydrogen peroxide. April 7.

8014 (1908). Lynum. *See under II.*

26,027 (1908). Act.-Ges. f. Kohlendestillation. *See under II.*

2522 (1909). Johnson (Badische Anilin und Soda Fabrik). *See under XIV.*

VIII.—GLASS, POTTERY, AND ENAMELS.

APPLICATIONS.

7685. Cliff. Revolving kilns for making enamel and other pottery ware. March 31.

7823. Sievert. Manufacture of glass plates. [Comprise in No. 25,042, Nov. 20, 1908.]* April 1.

8381. Neale and King. Material for use in decorating earthen, china, and similar ware. April 7.

8594. Rowart. Apparatus for the manufacture of glass in continuous sheets. April 8.

COMPLETE SPECIFICATION ACCEPTED.

7230 (1908). Sulman, Picard, and Heath. Application of metallic coatings to articles of glazed china, porcelain or earthenware. April 15.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

7696. Blackburn. Manufacture of bricks, &c. March 31.

8176. Gerbache. Process for preserving wood.* April 1.

8193. Soc. J. et A. Pavin de Lafarge. Manufacture of cement. (Fr. Appl., May 15, 1908.)* April 15.

8675. Mellersh-Jackson (Soc. J. et A. Pavin de Lafarge). Manufacture of cements. April 10.

COMPLETE SPECIFICATIONS ACCEPTED.

10,554 (1908). Nussbaum. Process for preparing wood. April 15.

16,376 (1908). Prince. Kilns for burning or drying bricks, tiles, &c. April 15.

25,833 (1908). Mecke. Making cement, mortar, and concrete, even when under pressure, watertight. April 7.

X.—METALS AND METALLURGY.

APPLICATIONS.

7519. Mackenzie (Stevens). Process for extracting metal from ore.* March 29.

7811. Macallum. Manufacture of steel. (U.S. App. Feb. 4, 1909.)* April 1.

8100. Farmer and Graham. Alloying iron with copper producing iron-bronzes and iron-brasses. April 5.

8163. Bloxam (Treibacher Chem. Werke). Manufacture of pyrophoric alloys.* April 5.

8287. Lockwood and Samuel. Oils and oily liquids for use in treating ores, &c. April 6.

8457. Mallmann. Crucible furnaces. April 7.

8682. Penhale and Mascall. Solvent for precious metals. April 10.

COMPLETE SPECIFICATIONS ACCEPTED.

2479 (1908). Nichols. *See under I.*

6888 (1908). Troeller. *See under VII.*

7227 (1908). Rosenberg. Depositing metals on metal surfaces. April 15.

7429 (1908). Herrenschmidt. Treatment of antimony and other ores. April 15.

13,146 (1908). Dor-Delattre. Extracting dust and fumes produced by zinc furnaces, &c. April 15.

14,926 (1908). Perry (Bismarckhütte). Refining steel in electric furnaces. April 7.

17,350 (1908). Siemens and Halske A.-G. Increasing the ductility of tungsten. April 15.

17,438 (1908). Siemens und Halske A.-G. Manufacture of objects of tungsten or of tungsten and nickel. April 7.
18,596 (1908). Chalas. Recovery of nickel from silicious ores. April 7.

19,585 (1908). Usine de Desargentation. Eliminating lead, arsenic, antimony, etc., from plumbiferous copper matter, ore, or alloy, and simultaneously recovering the copper as metal. April 15.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

7338. Nya Ackumulator Aktiebolaget Jungner, and Estelle. Alkaline accumulator.* April 1.

8194. Grondal Kjellin Co., Ltd., and Hårdén. Electric induction furnaces.* April 5.

8195. Nya Ackumulator Aktiebolaget Jungner, and Estelle. Positive electrodes for electrical elements with alkaline electrolyte.* April 5.

8261. Bradley and Thew. Electrodeposition of metals or alloys on other metals or alloys, fabrics, stone, plaster, or wood. April 6.

8443. Salpetersäure Ind.-Ges. Electric furnaces for treating gases or gas mixtures. [Ger. Appl., May 22, 1908.]* April 7.

COMPLETE SPECIFICATIONS ACCEPTED.

10,378 (1908). Cornelius. Electric furnaces. April 7.

13,502 (1908). Knowles. Electric furnaces. April 15.

5958, 5960, and 5962 (1909). Gibbs. Production of metallic articles by electrodeposition. April 7.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

APPLICATIONS.

7852. Swiftsure Synd., Ltd., Mellor, and Baildon. Manufacture or treatment of soap, oils, fats, &c. April 2.

8245. Noltenius. Immediate recovery of residuary oil from bleaching earths by the use of steam.* April 6.

8287. Lockwood and Samuel. *See under X.*

8674. Grant. Manufacture of soap.* April 10.

COMPLETE SPECIFICATIONS ACCEPTED.

15,466 and 19,140 (1908). Common and Hull Oil Manufacturing Co. Increasing the viscosity of castor oil and rendering it miscible with mineral oils. April 15.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, &c.

(A.)—PIGMENTS, PAINTS.

APPLICATION.

8532. Child and Johnston. Manufacture of printing and lithographic inks. April 8.

(C.)—INDIA-RUBBER.

APPLICATIONS.

8062. Dogny, Henri, and Veil-Picard. Manufacture of products from india-rubber or other plastic material.* April 3.

8271. Campbell. *See under XIV.*

XIV.—TANNING, LEATHER, GLUE, SIZE, &c.

APPLICATIONS.

7777. Molhant. Process for depilating hides.* April 1.

8271. Campbell. Substitute for leather or rubber. April 6.

8600. Mayo. *See under V.*

COMPLETE SPECIFICATIONS ACCEPTED.

7580 (1908). Pianko and Knaster. Manufacture of leather. April 15.

26,593 (1908). Müller. Production of imitation leather. April 15.

2522 (1909). Johnson (Badische Anilin und Soda Fabrik. Bleaching agent and its use for bleaching leather, glue, feathers, and straw. April 15.

XVI.—SUGAR, STARCH, GUM, &c.

APPLICATION.

8447. Boidin. Treatment of amylaceous materials.* April 7.

COMPLETE SPECIFICATIONS ACCEPTED.

7813 (1908). Boulton (Sparre). *See under XVII.*

18,237 (1908). McMullen. Manufacture of sugar. April 15.

XVII.—BREWING, WINES, SPIRITS, &c.

APPLICATION.

7989. Faulkner, Collett, and Collett. Malt extracts. April 3.

COMPLETE SPECIFICATION ACCEPTED.

7813 (1908). Boulton (Sparre). Production of products in addition to alcohol by fermentation of saccharine solutions preferably maltose. April 15.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; AND DISINFECTANTS.

(A.)—FOODS.

APPLICATION.

8041. Willmann. Processes of pasteurising milk. [U.S. Appl., May 25, 1908.]* April 3.

(B.)—SANITATION; WATER PURIFICATION.

APPLICATIONS.

7464. Leigh. Treatment of liquids in filter beds. March 29.

8296. Candy. Purification of water. April 6.

COMPLETE SPECIFICATION ACCEPTED.

26,013 (1908). Maccormac. Apparatus for the bacteriological treatment of sewage and other polluted liquids. April 15.

(C.)—DISINFECTANTS.

APPLICATION.

8270. Niblett. Production of a disinfecting or deodorising compound applicable also for bleaching purposes. April 6.

XIX.—PAPER, PASTEBOARD, &c.

APPLICATIONS.

7743. Wetter (Knoll und Co.). *See under V.*

8175. Rinman. Treatment of waste liquors from soda pulp mills. [Swed. Appl., April 14, 1908.]* April 5.

COMPLETE SPECIFICATIONS ACCEPTED.

17,810 (1908). Pierucci. Manufacture of papers for filtering and like uses. April 15.

18,600 (1908). Gestetner. Preparation and treatment of stencil paper. April 15.

23,947 (1908). Gunn. Bleaching pulp used in the manufacture of paper. April 7.

XX.—FINE CHEMICALS, ALKALOIDS,
ESSENTIAL OILS, AND EXTRACTS.

APPLICATIONS.

8069. Raschig. Manufacture of phenol esters chlorinated in the side chain, and of oxybenzyl alcohols, oxybenzaldehydes and oxybenzoic acids.* April 3.

8421. List, and Saccharin Fabr. A.-G. vorm. Fahlberg, List, and Co. Manufacture of *o*-sulphamidobenzoic acid.* April 7.

COMPLETE SPECIFICATIONS ACCEPTED.

7613 (1908). Brougham (Preyss). *See under 1.*

9855 (1908). Imray (Meister, Lucius, and Brüning). Manufacture of reduction products of oxyarylarsonic acids. April 15.

21,389 (1908). Lepetit. Para-ethoxyphenylamidomethyl alkaline sulphites and process of making same. April 7.

XXI.—PHOTOGRAPHIC MATERIALS AND
PROCESSES.

APPLICATIONS.

7518. Cunningham. Treating photographic prints. [U.S. Appl., April 9, 1908.]* March 29.

7800. Hans. Producing chromate glue pictures on metal, porcelain, glass, &c.* April 1.

COMPLETE SPECIFICATIONS ACCEPTED.

7087 (1908). Donisthorpe. Photographic sensitive surfaces. April 7.

20,111 (1908). Soc. Anon. des Plaques et Papiers Photographiques A. Lumière et ses Fils. Screen or plate for direct colour photography. April 15.

XXII.—EXPLOSIVES, MATCHES, &c.

COMPLETE SPECIFICATIONS ACCEPTED.

7921 (1908). Boulton (La Motte). Explosives and process of making the same. April 15.

13,890 (1908). Larsen. Waterproofing blasting cartridges. April 15.

Birmingham Section.

Meeting held at Birmingham University on Thursday,
March 11th, 1909.

MR. HARRY SILVESTER, B.Sc., F.I.C., IN THE CHAIR.

INFLUENCE OF SMALL QUANTITIES OF ARSENIC AND ANTIMONY ON COPPER.

BY A. H. HIORNS AND S. LAMB, A.R.S.M.

COPPER AND ARSENIC.

Arsenic is well known to have a beneficial effect on the strength and durability of copper for many purposes, but there is great divergence of opinion as to the quantity of arsenic that should be present without prejudicial effects. In Watts' Dictionary of Chemistry, it is stated that with 0.15 per cent. the metal becomes somewhat brittle when cold and very brittle at a red heat, but it is not stated what the other impurities of the copper were, hence the statement is of no value. Hampe (*Chem.-Zeit.*, 1892, 16, No. 42) found that 0.5 per cent. of arsenic produces no bad results, and even when the arsenic is increased to 1 per cent. only a slight degree of red shortness, but no cold shortness, could be noticed. He found that copper with 0.8 per cent. of arsenic could be drawn into the finest wire: that small percentages of arsenic (0.216 per cent.) even increase the tenacity of copper, but diminish its electrical conductivity. Stahl (*Inaugural Dissertation*, Tübingen, 1886) states that a small percentage of arsenic prevents copper from becoming porous. Hiorns (this J., 1906, 616) showed that copper with arsenic up to 0.4 per cent. was very malleable in the cold; that the same result applies to arsenic in the presence of antimony, the proportions of each element being 0.2 per cent.; that arsenic is beneficial in copper in neutralising the bad effects of lead and even bismuth. In fact, that arsenic in the presence of antimony, makes the copper more malleable than it is with antimony alone, although antimony alone, when not above 0.2 per cent. is present, only slightly impairs the malleability of copper; and that arsenic in copper is highly beneficial, because it deoxidises cuprous oxide, which tends to destroy the malleability of copper. Johnson (*Birmingham Metallurgical Society*, 1906) states that copper with 0.5 per cent. arsenic, has, in the cast state a tensile strength of 10 tons per square inch, and 24 per cent. elongation. After forging, whilst hot, the tenacity was raised to 12.75 tons and an elongation of 35 per cent. By being subjected to further mechanical treatment by rolling, the tenacity was 14 tons, and the elongation 48 per cent. After being highly wrought and cold drawn the tenacity of the same cast copper

was raised to 15.9 tons and the elongation 24 to 50 per cent.; the specific gravity was also raised from 8.83 in the cast state, to 8.896 in the worked state. He further states that arsenic has a remarkable effect in reducing the conductivity of copper. A sample of electrolytic copper to which 0.06 per cent. of arsenic was added, had its conductivity reduced as much as 19 per cent.

Percy (*Metallurgy*, p. 288) gives the conductivity of copper containing a trace of arsenic as 57.8 and copper containing 2.8 per cent. of arsenic as 13.14.

The mode of procedure in the preparation of the alloys was, first, to make an alloy of pure copper and arsenic. This alloy was used as a source of arsenic instead of introducing it into the copper in the elementary state.

Preparation of copper with high arsenic content.—The copper was melted in a fireclay crucible using the coke furnace. Metallic arsenic was added to the copper and a very rich copper-arsenic material was thus formed. It was kept molten for several minutes in the furnace, and well stirred with a charred stick of wood, after which it was poured into an iron mould which had previously been blacked over an ordinary gas flame. The material was allowed to cool gradually, and then powdered

FIG. 2.

in a large iron mortar. Any pieces of iron which it contained were separated by means of a large magnet. The whole was then carefully mixed and sampled for analysis.

Methods of analysis.—0.5 gm. was dissolved in 5 c.c. of strong nitric acid and 5 c.c. of water in a small beaker. When dissolved the solution was evaporated (until crystals commenced to form) with 3 c.c. of strong sulphuric acid. Cold distilled water was added and the crystals dissolved. The volume of the solution was made up to 50 c.c. The copper was extracted by electrolysis, with a current of 1.5 amps. and a voltage across the terminals of 3.3 volts, a rotating cathode being used. Under these conditions, the whole of the copper was removed in ½ hour. The cone was first washed by distilled water, then immersed in alcohol, and finally in ether. It was then dried in an oven at about 50° C. for 5 minutes, weighed, returned to the oven for another 5 minutes, and then re-weighed. The cathode was weighed before and after the experiment, and thus the copper contents found.

Testing deposit.—The deposit, which was of a fine salmon pink, was dissolved in dilute nitric acid and evaporated to near dryness, and sulphuric acid again added to remove the nitric acid. A strong solution of potassium hydroxide

Apparatus for Arsenic determination

FIG. 1.

was added and the solution well boiled for 10 minutes, when it was filtered to remove the copper oxide, hydrogen sulphide passed into the alkaline solution, and any precipitate filtered off. To the solution hydrochloric acid was added until it was just acid, and then hydrogen sulphide was passed for 20 minutes. A very slight precipitate was produced which was collected on counterpoised filters, washed by carbon bisulphide to remove sulphur, and then weighed as arsenious sulphide.

Copper and arsenic may be separated if the current density, speed, etc., are properly adjusted, as was found by varying it in other experiments.

Arsenic in solution after copper was removed by electrolysis.—The solution was evaporated nearly to dryness, and then 10 c.c. of strong nitric acid added and allowed to stand for 15 minutes on the hot plate. The solution was then diluted to 20 c.c. with water, and strong ammonia solution added until just neutral; 10 c.c. were then added in excess, and then 2 grms. of magnesium chloride and 3 grms. of ammonium chloride in 5 c.c. of hot water (just made alkaline by ammonia) added. The solution was then well agitated for six hours at intervals and the arsenic was thus precipitated. The precipitate was collected, washed with 10 per cent. ammonia, and then dried and ignited apart from the filter, and weighed as $Mg_2As_2O_7$. The copper in solution was so small that no coloration could be observed in many cases. When, however, any was observed, however slight, it was determined colorimetrically, using ammonia and a standard copper solution.

Results:—

Copper	67.340	Arsenic	32.691
"	67.320	"	32.703
"	67.340	"	32.650
Average	67.333	Average	32.681

The following alloys were prepared:—

Desired.	Analysis.	Desired.	Analysis.
0.05	0.05	1.00	1.04
0.10	0.098	1.50	1.395
0.20	0.205	2.00	1.740
0.40	0.382	2.50	2.244
0.50	0.471	3.00	2.581
0.60	0.581	3.50	2.893
0.70	0.701		

The copper used for the preceding and subsequent alloys was pure electrolytic, which contained a trace of iron, amounting to 0.02 per cent.

The method employed was to melt the calculated amount of pure copper in a crucible made of compressed carbon and then stir well with a charred stick, in order to remove any oxide which may have formed. The calculated quantity of rich copper-arsenic alloy was then added, wrapped in small pieces of tissue paper, and immediately stirred with a charred stick. The alloy was then poured into an iron mould, previously heated and then blackened by an ordinary gas flame.

First set of alloys.—Made as indicated. Weight of ingots = 2000 grains.

They were cast in an open mould, measuring 4 ins. by $\frac{1}{2}$ in. and $\frac{1}{2}$ in. thick. The castings were allowed to cool in the mould and then rolled down to a sufficient degree with suitable annealings in order to obtain pieces of the requisite thickness to draw into wire.

Up to 0.1 per cent. the alloys showed a slight elevation of the surface. From 0.2 per cent. up to 0.4 per cent. the surface was level, but above 0.5 per cent. a distinct furrow was observed, which appeared to increase as the percentage of arsenic was increased. Below 0.2 per cent. the ingots tended to be a little blowholy, but all others were very sound. Those containing above 0.5 per cent. were perfect and no blowholes were seen. We tried to cast an ingot of pure copper, but always found it filled with blowholes, however carefully it was melted and cast. The metal became lighter in colour as the percentage of arsenic was increased. At 3.5 per cent. the metal was almost the colour of gun-metal. The metal

FIG. 3.

appears to file better as the percentage of arsenic is increased. No clogging occurred above 0.5 per cent. arsenic.

Hardness.—The ingots were filed at the upper surface and polished, and then their hardness determined in terms of that of an ingot of pure copper. The scleroscope and the intensifier hammer were used. With increasing arsenic contents the metal became harder, and the following are the results.

Percentage of arsenic (supposed).*	Rebound of hammer.
0	7 degrees
0.05	8 "
0.40	9 "
1.50	10 "
3.00	11 "

* See analyses above.

Pieces were cut off each of the ingots for microscopic investigation.

Preparation of wires for conductivity tests.—The ingots were rolled cold down to 0.135 inch with two annealings at a dull red heat (650° C. about). The strips so prepared were sheared by hand and a strip about $\frac{1}{4}$ inch square was used to prepare the wire. The prepared strips were then filed down to just fit tightly in the first hole of a drawplate, and after annealing in a Bunsen flame until just red, they were allowed to cool, and then the wires were drawn first on a small drawbench and then by hand.

Notes on drawing.—Pure copper draws very well, but the blowholes always cause it to break. Every break was across a blowhole. Length, 30 inches. Passed 50 hole. Annealed after 17 hole in drawing. Left hard. 0.05 per cent. arsenic. Strip drawn to 50 hole. Left hard. Annealed after 5 and 17 holes. Gave a good wire. Draws well. 0.1 per cent. arsenic. Drawn to 50 hole. Annealed after 5 and 17 holes. Left hard. Good wire and draws well. 0.2 per cent. arsenic. Drawn to 50 hole. Annealed only after 17 hole. Left hard. Very good wire and draws well. 0.4 per cent. arsenic. Drawn to 50 hole. Annealed after 17 hole. Good wire. Left hard. 0.5 per cent. arsenic. We experienced difficulty in getting

a wire from this alloy. Three attempts were made and we always found that the wire broke during drawing, but no blowhole could be seen on the fracture. Surface cracks, however, were seen on the ingot after rolling, and probably these were in no small measure accountable for the rupture. Drawn to 50 hole. Left hard. Annealed after 17 hole. Rough wire. 0.6 per cent. arsenic. Drawn to 50 hole. Annealed after 17 hole. Left hard. Wire again tended to be weak owing to cracks on the surface which were small. 0.7 per cent. arsenic. Drawn to 50 hole. Wire broke twice during drawing. Small surface cracks evident. Left hard. Annealed after 17 hole. 1 per cent. arsenic. 50 hole passed. Annealed after 17 hole. Good wire. Left hard. 1.5 per cent. arsenic. Passed 50 hole. Annealed after 17 hole. Good wire. Left hard. 2.0 per cent. arsenic. Passed 50 hole. Annealed after 17 hole. Good wire. Left hard. 2.5 per cent. arsenic. Passed 50 hole. Annealed after 17 hole. Left hard. Good wire.

FIG. 4.

From the remains of the strips after the piece for wire drawing had been cut off, filings were taken and cleaned by a magnet. These were reserved for chemical analysis.

Analysis.—Alloys were analysed by distillation with a hydrochloric acid solution of ferric chloride. (See Figure 1.) This was made by digesting 200 grms. of "Venetian red" in one litre of strong hydrochloric acid, just below its boiling point, for 24 hours, and making the solution up to one litre with strong hydrochloric acid. The weighed quantity of copper (1 to 2 grms.) was then added to the flask and 50 c.c. of solution poured down the funnel, and distillation continued until the residue became pasty. Then another 50 c.c. of hydrochloric acid was added, and the solution again boiled until nearly dry. The distillate, which was collected, was poured into an 8-inch porcelain dish and just neutralised with ammonia. Hydrochloric acid was then added to make just acid, and then 4 grms. of sodium bicarbonate added and allowed to dissolve. Starch was used as an indicator, and then the solution was titrated with a solution of iodine, 1 c.c. of which was equivalent to 0.001 grm. of arsenic. In a blank experiment one grm. of pure copper needed 0.8 c.c. of iodine solution. Those alloys above 0.5 per cent. were also estimated by the revolving cathode, as before explained.

Rolling tests of copper-arsenic alloys.—A set of alloys was made with the following percentages of arsenic: 0.05, 0.1, 0.2, 0.4, 0.7, 1.0, 1.5, 2.0, 2.5, 3.0, and 3.5 per cent. The ingots before rolling were 2.36 inches long, 0.139 inch diameter (thick), and 0.945 inch broad. This set was then passed through the rolls one after the other, so that they should have precisely the same treatment. They were rolled cold down to the smallest possible gauge of our rolls. After rolling they were 12.5 inches long (about); 1 inch broad, and 0.02 inch thick.

Up to 0.2 per cent. the ingots frayed slightly on the edges, probably due to enclosed oxide. Between 0.2 and 0.5 per cent. the metal stood the test exceedingly well and the edges were perfect. Above 0.5 per cent. up to 2 per cent. the metal again showed cracks at the edges. Above 2 per cent. up to 3.5 per cent. the

metal rolled exceedingly well, and did not produce any large edge cracks. The colour of the material becomes lighter as the percentage of arsenic increases.

This is of course purely cold work, and we do not consider the higher percentages would have stood a hot rolling test as they stood the cold rolling test. Pure copper stood the rolling test very well.

Electrical resistance and conductivity of alloys.—Wires were made from each of the alloys.

Figs. 2 and 3 give the curves for electrical resistance and conductivity.

The method of determining resistance was the Post Office box method. A D'Arsonval galvanometer was used to give the point when balance was obtained, and owing to the distance from the mirror being fairly great, the balance could be obtained with great accuracy.

COPPER-ANTIMONY ALLOYS.

Copper-antimony alloy. The copper was melted in a clay pot and antimony added until about $2\frac{1}{2}$ times the weight of the copper had been added. It was readily taken up, and the material became very fluid. Antimony was, to a certain extent, volatilised, as evidenced by a white smoke continually rising from the pot. The material was stirred with a charred stick and poured into an iron mould which was blackened by a gas flame. This alloy was very brittle, and could be powdered in a large iron mortar. Iron was again separated by a magnet. The powdered material was sampled and analysed by the following method:—0.5 grm. of the alloy was dissolved in 20 c.c. of hydrochloric acid and 5 c.c. of nitric acid, and evaporated to a small bulk, but no precipitate was allowed to appear. 10 c.c. of hydrochloric acid were again added to remove all traces of nitric acid. The solution was then poured into a solution of 30 grms. of potassium hydroxide and boiled. The black precipitate of copper oxide was allowed to settle, filtered, dissolved in dilute nitric acid, and the copper separated by the revolving cathode. Hydrogen sulphide was passed into the alkaline solution, and any black cuprous sulphide which was pre-

FIG. 5.

precipitated was collected and added to the former solution. The solution was made acid by hydrochloric acid and kept warm for one hour, when the antimony was precipitated as antimonious and antimonie sulphides. This was collected, washed by carbon bisulphide to remove sulphur, then washed into a weighed porcelain dish and evaporated to dryness, heated to 230° C. in carbon dioxide, and weighed as antimonious sulphide.

An attempt was made to separate the antimony from the copper by oxidation with nitric acid. The solution containing the copper was electrolysed as in the case of the copper-arsenic alloy. It was found impossible to remove the copper from the solution, however the current was varied or whatever was the speed of the cathode. The precipitated copper always contained antimony, however small the amount left in solution.

A complete set of alloys was prepared having the following percentages of antimony. They were made by adding the requisite amount of rich alloy in the same way as in the arsenical alloys.

Ingots were made 0.163 inch thick, 3.0 inches long, and 1.5 inches in diameter. These were rolled down to 0.1065 inch and then sheared in order to produce the strips for wire drawing. The alloys all showed faint cracks along a plane at right angles to the rolls. The cracks increased as the percentage of antimony increased. The limit at which we could draw wire was 0.6 per cent. antimony. Above this, however carefully annealed, the sample broke in the wire drawing.

Every ingot tended to have blowholes, even in the

FIG. 6.

higher percentages, and it shows conclusively that antimony has not the effect that arsenic has in removing or preventing their formation. With increasing antimony contents the alloy becomes much lighter in colour. Antimony and arsenic appear to lighten the colour in about the same degree.

Effect of antimony on the hardness.—According to Scleroscope measurements antimony does not confer hardness to the same degree as arsenic.

The ingots made for rolling were 2.35 inches long, 0.139 inch broad, and 0.945 inch thick. These were cold rolled down to the same dimensions as the arsenic alloys. All the alloys of antimony cracked during rolling to a much greater degree than the corresponding arsenic alloys.

Electrical resistance.—The alloys were first made into suitable wires, and then the resistance measured in the same way as with the arsenic alloys.

MICROSCOPICAL EXAMINATION.

Copper-arsenic alloys.—The sections selected for examination were transverse and obtained from ingots which were cooled quickly and very slowly respectively. They were polished by hand in the usual way on graded emery papers and finally on chamois leather, charged with the finest rouge. The photo-micrographs were taken with an arc lamp, all with the same magnification of 100 diameters so as to make them strictly comparable. The illumination was normal in all cases.

In all the alloys from 0.05 to 3.5 per cent. the general structure was found to be practically of the same general pattern. This consisted of dark polygonal crystals, very soft and difficult to get entirely free from scratches: these were bounded by a lighter coloured and harder material, which was assumed to be a solid solution of arsenic in copper because it was structureless. In the quickly cooled alloys, the whole mass was found to consist of these two constituents alone; the only difference being that with increase of arsenic the boundaries became wider and the polygons correspondingly less in area. The latter do not consist of pure copper, inasmuch as they darken on etching, whereas pure copper does not. It

FIG. 8.

is very probable, however, that the boundaries contain the greater portion of the arsenic, for reasons which will be given when discussing the slowly-cooled alloys. It may be stated that the small blowholes, which are invariably present, always appear in the boundaries and not in the interior of the crystals, from which it may be safely assumed that the boundaries were the last portions to solidify. The above-mentioned alloys, then, consist of soft crystals bounded by a harder and more brittle material, which, while it greatly hardens and strengthens the mass as regards tenacity, diminishes its ductility and eventually makes the whole mass more brittle.

The slowly-cooled alloys were prepared by melting 500 grains of the alloy under charcoal, covering with a lid, and then transferring to a gas muffle and maintaining at a temperature of 700°C . for two hours. The gas was then turned off, and the crucible left to gradually cool. The button was then sawn through at right angles to the cooling surface, and the piece polished and etched as before. Much the same general structure was observed as in the quickly-cooled alloys, but both the constituents were very much larger in area for any one crystal and its boundary. There was much less definition between the crystals and the boundaries, the one passing insensibly into the other. There was also the same proportional diminution in the size of the crystals with increase of arsenic as with the quickly-cooled samples. There was, however, one notable difference. In the boundaries appeared a new structureless constituent, of a light blue colour, which is very probably the chemical compound, Cu_3As . Very small quantities of this constituent were observed in the alloy with 0.21 per cent. of arsenic, and gradually increasing quantities as the percentage of arsenic increased. The solid solution, which forms the boundaries, is super-saturated with arsenic, and, on slow cooling, the excess separates in the form of the above-mentioned compound. In the 5 or 6 per cent. alloys, slowly cooled, the light coloured boundaries have disappeared and are replaced by branching masses of the light blue compound, which, however, is not continuous. Seeing, then, that the boundaries eventually yield this chemical compound, it may be fairly assumed that they contain the greater portion of the arsenic present and only a small portion is retained in the copper crystals.

Fig. 4 contains 0.25 per cent. arsenic quickly cooled.

Fig. 5 „ 0.22 per cent. „ slowly „

Fig. 6 „ 5.00 per cent. „ quickly cooled,

and shows the chemical compound which has separated out from the boundaries.

Copper-antimony alloys.—The sections obtained for microscopic examination were prepared in a similar way to those for the copper-arsenic alloys. In all the alloys from 0.1 to 3.5 per cent. of antimony, the structure was found to be practically the same. Both slowly and quickly-cooled samples were examined. The structure consists of dark polygonal crystals, very soft and difficult to get free from scratches, bounded by a lighter and harder material. As the crystals take a dark colour on a short immersion in hydrochloric acid, they cannot consist of pure copper, and therefore contain a little antimony. Prof. Arnold ("Engineering," Feb. 7, 1896) remarks concerning copper with 0.2 per cent. of antimony,

"The latter metal produces very thick brown cell walls, which seem in area to be altogether out of proportion to the percentage of antimony present. On examination with a high power the antimonide meshes are found to possess a compound structure consisting of alternate dark and light laminae, suggesting that in the first instance an attenuated antimonide involves the copper cells at a high temperature, but at a low temperature the walls split up into plates of pure copper alternating with those of a less basic antimonide."

In our experiments the material of the boundary walls was structureless, with a magnification of 1000 diameters, for alloys with small percentages of antimony. The alloys with higher percentages of antimony contain small crystals of impure copper surrounded by wide boundaries of varying widths, which contain a neutral gray or bluish constituent in the form of irregular patches. As this constituent separates out from the boundaries it is inferred that the boundaries consist of a solid solution of antimony in copper from which the chemical compound, Cu_3Sb , separated on slow cooling. The amount of this structureless compound increases with increase of antimony, until the boundaries are entirely replaced by it.

Fig. 7 contains 0.4 per cent. antimony, quickly cooled

DISCUSSION.

The CHAIRMAN said this important paper could not have been delivered in a more appropriate place, because more copper was consumed in Birmingham than in any other manufacturing centre. He hoped that through the agency of the Institute of Metals, copper and non-ferrous metals would, by means of papers similar to the one read to the meeting, be placed on the same level as iron and steel had been through the agency of the Iron and Steel Institute.

Professor TURNER said that 20 years ago certain elements were known to have ill-effects on steel, and it was assumed that the same would occur with regard to copper, and that it was necessary to have a perfectly pure copper in order to get a good material. It had long been known, however, that arsenic for certain purposes was not merely not injurious, but that it was absolutely beneficial or necessary. Many years ago he analysed a sample of copper which contained about 0.75 per cent. of arsenic, and the material was, apparently, quite satisfactory. For wrought copper for certain purposes arsenic was regularly added and was satisfactory. Arsenic had two distinct effects on copper. In the first place the tenacity of the copper was distinctly increased, especially at high temperatures, while its working properties were not seriously interfered with; and, on the other hand, there was a very marked reduction in the conductivity. It would be interesting to compare the curves (which had been shown) with reference to the effect of antimony and arsenic on conductivity with the results and theoretical conclusions of Guertler (Z. Anorg. Chem., 1906, 51, 397; 1907, 54, 58). His own impression was that the figures shown would be found to correspond with the general laws that had been adduced. That antimony had less effect than arsenic would be in accordance with those laws. In the determination of arsenic, he was doubtful as to the wisdom of boiling the iron arsenic solution down so as to become syrupy and then distilling again, because the ferric chloride might, if overheated, liberate an appreciable amount of chlorine, and if one were working by the method described, that chlorine might interfere. He was interested in the scleroscope tests, and he thought the results would agree with certain observations he had been making lately not on arsenic, but on copper, under various circumstances and with various elements. When using this fascinating instrument they would in testing various kinds of metals find considerable enlightenment, and many puzzling observations.

Mr. F. PLATTEN said that many years ago it was the custom of all engineers to specify that arsenic should be reduced to less than 0.15 per cent. There was now, however, general agreement that the presence of arsenic in copper was beneficial. All engineers specified it, in certain amounts, up to 0.55 per cent. It was certainly useful to have the matter followed out to its limits as had

been done by the authors of the paper, and the curves put on record. These experiments were all done by erieble, but he would like to ask the authors if they could give any explanation of the following facts. When producing a copper containing a certain percentage of arsenic, it was the custom in the refinery to add the arsenic, because arsenical copper did not come into the market in any considerable quantity. It came mostly in Bessemer bars, and the arsenic was blown out, so that they had to add it. When they added arsenious oxide the effect on the tensile strength of copper was practically negligible, but if metallic arsenic were added to the copper in the refinery furnace, there was an increase in the tensile strength. The addition of the arsenious oxide seemed to have no effect except on the question of conductivity. As to the analysis of arsenical coppers, engineers specified a copper with 0.3 to 0.5 per cent. arsenic, and with this margin at any rate for works purposes, it was sufficiently accurate to titrate the distillate direct. An absolutely accurate result running into the third decimal place could be obtained by precipitating the arsenic from the distillate in the form of sulphide, dissolving it in water, and then titrating as mentioned in a paper he read before the Society some years ago.

Mr. O. F. HUDSON said the two photographs showing the structure of quickly-cooled and slowly-cooled alloys, showed that in the case of arsenic the copper could hold 0.2 per cent. at least in solid solution. He understood that the authors were of the opinion that the dark and light portions represented in the slowly-cooled alloy two constituents; but he thought it was clear that they showed a simple solution of the arsenic and copper: the dark and lighter portions merged gradually one into another, darker portions representing the parts slightly freer from arsenic.

Mr. E. A. LEWIS said his experience of arsenical copper made in the refineries was that it always contained a certain percentage of oxygen, and nearly always as much as in a non-arsenical copper. It seemed that the arsenic did not remove the oxygen. With regard to the structure of antimonial copper, Arnold stated some years ago that the copper-antimonial boundary was a compound structure. It seemed that it depended entirely on the rate of cooling, and the weight operated upon. With regard to the point raised about estimating arsenic, he did not find it necessary to evaporate down to dryness. He took a comparatively long time for the distillation—about two hours—and titrated arsenic direct.

Mr. D. M. LEVY suggested that the authors of the paper should continue their investigations, and show the effect of increasing quantities of oxygen on the alloys that they had prepared. That was a point of practical importance. The general idea, he thought, was that arsenic combined with copper to form a compound which passed into solid solution, and which might separate, on further cooling, to form the boundaries which interfered with the electric conductivity and similar properties. The effect of oxygen might be to form an insoluble copper arsenate, which would collect the arsenic into the form of nodules and not have so damaging an effect on the conductivity and other properties of arsenical copper. Some years ago a paper was published, showing that the effect of arsenic on copper was not so great unless there was a certain quantity of lead present. Oxygen was not mentioned, but it seemed to him, from a large number of tests on metal, that the presence of arsenic and lead was more desirable than the presence of either of them alone. It would be interesting to have some tests done on the hot rolling or drawing of those alloys to see if those boundaries might pass into solution at higher temperatures and show better working properties.

Mr. E. J. BARTY said he had taken several photographs in regard to this question of arsenic in electrolytic copper. He started with a high conductivity copper which always gave the same definite structure. In the electrolytic copper used there was about 0.1 per cent. of oxygen and 0.1 per cent. of other impurities. When he added metallic arsenic to that, in small proportion, he found that the structure was absolutely changed. If he added copper oxide to introduce oxygen, as long as the total impurities were less than 0.5 per cent., the structure approached the electrolytic structure again, but the

crystal boundaries became pitted, which he thought was due to the oxygen from the bismuthates and arsenates which separate at the crystal boundaries on cooling. He knew that in impure coppers with oxygen added the conductivity was much better than when the oxygen was not there, and by melting under charcoal, one got low conductivity again.

Mr. F. JOHNSON pointed out that the authors had not spoken of the effect of arsenic on copper at high temperatures. It was this particular property which seemed to be the great point. Another great advantage of arsenic was that it raised the point at which copper became annealed. It also made it tougher at all temperatures. These facts were of immense importance when copper had to be used for loco, plates and tubes. The use of arsenic considerably modified the effect of bismuth. He was surprised to hear that copper containing 0.5 per cent. of antimony, was hard to draw into wire, and a paper read by Mr. T. JOHNSON in 1906, before the Birmingham Metallurgical Society, contained a table bearing on this point. In this paper he gave a copper with 0.5 per cent. of antimony which had a tensile strength of 15.6 tons per square inch and an elongation of 45 per cent., and had had a good deal of work put on it. That, he thought, must be due to the fact that the copper was a refined copper containing oxygen as well as antimony. He thought the hardness of the copper quoted by the authors was due to the fact that it contained no oxygen.

Mr. A. H. HORNES, in reply, referred first to some peculiarities he had detected in carrying out the experiments. Mr. Stansbie had read a paper on the effects of small quantities of elements on copper with regard to their action with nitric acid. From those experiments he was led to the conclusion that 0.215 per cent. arsenic in copper was a critical point—that above and below that percentage there was a different action and that different amounts of gases were given off. From some experiments which he conducted some time ago on the effect of arsenic on copper, he found when he arrived at a certain percentage, that a blue constituent, totally different from the others, separated out on the boundaries. On increasing the quantity of arsenic this blue compound increased in quantity, until finally he arrived at a percentage when the whole mass consisted of the blue compound. After analysis that was found to be a chemical compound containing 28.34 per cent. of arsenic. From that he was led to state with considerable certainty that the small quantities of this blue substance separating out, even when the percentage of arsenic was small, were the same compound, and he was therefore led to consider that the influence of arsenic on copper was largely due to this compound. He was of opinion that this compound, Cu_3As , in copper was in solid solution under certain circumstances; in other circumstances it separated out. They found when there was as low as 0.22 per cent. of arsenic there was, on very slow cooling, a slight separation of this compound. That did away with the transformation point at 0.215 per cent., because they were led to expect if no separation could be brought about by long cooling below 0.25 per cent., that that would show the reason why there was a difference in the properties below and above that point. It seemed reasonable to suppose that by extremely long-continued cooling and with the smallest percentage of arsenic this compound might separate out. Did this chemical compound therefore have any influence on the properties of the copper? He thought it did. Those properties would differ according as this chemical compound was in the free state or in the state of solid solution. To their surprise they found that in the neighbourhood of 0.5 per cent. arsenic there was a difference in the malleability of the copper. From these observations he was led to consider that it was not safe to introduce more than 0.2 per cent. of arsenic into copper, although the quantity of the chemical compound on slow cooling made little difference. But as one gradually increased the percentage, the arsenic became more and more deleterious. They found between 0.5 and 1 per cent. the malleability seemed to diminish, and when they passed 1 per cent. and got up to 2 per cent. and 3 per cent. they had a metal which rolled almost perfectly. It was harder

than pure copper. There was more of this chemical compound separated out, so it seemed that the separation of the compound, which always took place in the boundaries, had little influence upon the malleability and the conductivity of the copper with these higher percentages of arsenic. But when a certain amount was separated out, the property seemed to go back again. With a small percentage of arsenic—under 0.5 per cent.—the copper ought to be more brittle by slow cooling than by quick cooling. By rapidly causing the metal to consolidate so as to prevent the separation of this compound, the metal ought to be more malleable than when slowly cooled. He would like to ask Mr. Platten whether the same quantity of arsenic was found in the finished copper as in the case of adding metallic arsenic.

Mr. PLATTEN: Exactly.

Mr. HORNES replied that it could not be a matter of the arsenic not being reduced, and remaining as oxide. It was possible that when the oxide was reduced, if the arsenate were not formed, and these reversible actions took place, it might form copper oxide. With a certain quantity of arsenic introduced into copper, the first small proportions acted by reducing the oxygen in the oxide of copper because they found, that with small percentages of arsenic, the added amount of arsenic was in every case lower by analysis. But when they arrived at a certain percentage, the amount of arsenic was practically the same. They assumed that a certain quantity of the arsenic acted in reducing the copper oxide. With regard to the micro-structure of the alloys, with the point raised by Mr. Hudson, he was quite in accord. He had not been able to confirm Arnold's experiments about the double line. Arnold considered there was a line running through the boundary separating it into two divisions, something like the action of bismuth in copper. In investigating the action of oxygen on copper, the difficulty was in the analysis of oxygen. Perhaps the most important question was that in relation to the action at high temperatures. Many alloys had been tried, to find what was the effect on the mechanical properties by an increase of temperature. Aluminium bronze, for example, was a most excellent metal in the cold, but it was absolutely fatal for rivets in copper plates in fire-boxes, because in a short time it would scale badly, and become very weak, and the copper plate itself would be distorted. As arsenic was put into copper for the purpose of resisting rupture at high temperatures, the question was of supreme importance. It seemed that arsenic had, too, that extremely valuable property of enabling copper to resist the corrosive action of the gases, as well as wear and tear; and he believed that copper, with a certain quantity of arsenic, acted better than any other alloy, save, perhaps, manganese bronze. But copper with manganese had the disadvantage that if it was brought into flame it corroded. They might say that copper with arsenic was the most valuable of all the metals for resisting high temperatures, and the question which arose was only as to how much arsenic might be safely introduced.

Mr. LAMB referred to the question of estimating the amount of arsenic in copper. He agreed with Professor Turner that care was necessary in heating down to a syrup. Care was necessary that the flame did not come into contact with the side of the retort, or chlorine was liberated. It was well to use a low flame and an asbestos pad. Mr. Platten said it was a rough works method. He found it could be made accurate to less than 1 per cent. if a weak solution of iodine was used. He found that 0.8 c.c. was used when one grain of pure copper was distilled with the same amount of solution. Taking the alloy, 0.1 per cent. of arsenic, they found it came to 0.098. Distilling to dryness was not necessary. Taking a low bulk was necessary with the high percentage alloys. Up to 1 per cent. it might not be necessary, but after that it was necessary to evaporate to syrup and distil a second time. He found that answered with copper precipitates. They were distilled with 50 c.c. of the solution, and then the arsenic determined. The bulb was put back and distilled with another 50 c.c., but not taken to dryness. An appreciable quantity of arsenic then came over, and by reducing to dryness the last traces of arsenic were removed.

London Section.

Meeting held at Burlington House on Monday, April 5th, 1909.

MR. E. GRANT HOOPER IN THE CHAIR.

THE ACTION OF SULPHURIC AND NITRIC ACIDS IN THE NITRATION OF CELLULOSE.

BY C. NAPIER HAKE AND MARCUS BELL.

A previous investigation, "On the formation of sulphuric esters in the nitration of cellulose and their influence on stability" (Hake and Lewis; this J., 1905, 374), confirmed the formation of sulphuric esters in cellulose nitrates prepared with mixtures of nitric and sulphuric acids (Cross and Bevan, Ber., 1901, 34, 2496). Further investigation was directed to the conditions which govern the formation of mixed esters during nitration, and to the properties of the products.

Our experiments have covered such a wide range, and suggest so many new points of interest, that it has been found impossible to bring the whole of the work to completion in the time at our disposal. We have therefore confined ourselves in this communication to the study of the action of concentrated sulphuric and nitric acids in contact with cellulose at temperatures within reasonable limits. All the experiments were carried out in a laboratory at temperatures between 10° and 20° C. Filter paper was found to be the most convenient form of cellulose with which to work, being both pure and practically uniform in physical condition. It is more easily handled than cellulose in the form of cotton wool or raw cotton, the experimental conditions being more easily controlled. The majority of our experiments were therefore made with cellulose in the form of Swedish filter paper.

The acids used were commercial concentrated sulphuric and nitric, the sulphuric acid containing from 92 to 96 per cent. of H_2SO_4 , the nitric acid from 91 to 95 per cent. of HNO_3 . The nitric acid contained from 2.5 to 3.5 per cent. N_2O_4 . The acid mixtures used for nitration contained from 5 to 8 per cent. of water.

In carrying out the experiments, the following conditions were observed, except in cases where special conditions are mentioned:—(a) The cellulose, previous to nitration, was dried in the water oven, and allowed to cool under a desiccator. (b) A large excess of acid mixture to cellulose (at least 50:1 by weight) was taken, the weight of acid mixture used being such that 12–13 parts of nitric acid were present for each part cellulose. (c) After nitration, the products were drowned in a large excess of cold water, and washed in cold running water until neutral, i.e., until after standing for two hours in a small quantity of distilled water, the water gave no indication of free acid.

The estimations of combined nitric and sulphuric acids were made on the thoroughly cold washed products. The degree of nitration was found by estimation of nitrogen in Lunge's nitrometer, the combined sulphuric acid by fusion with alkali, precipitating and weighing as barium sulphate.*

With a view of determining the chief factors governing the formation of sulphuric esters during nitration, the experimental conditions were varied in respect to:—(1) Temperature of the acid mixture. (2) Proportions of acid mixture to cellulose taken. (3) Proportion of water in nitrating acids. (4) Relative proportions of sulphuric and nitric acids in the nitrating mixture. (5) Physical condition of the cellulose. (6) Time of contact between cellulose and acids.

(1) and (2) We find that variations of temperature well within practical limits (0° C.—25° C.), both in mixing the acids and during the process of nitration and drowning, or variations in the excess of acid mixture to cellulose taken (25 to 200 parts of acid mixture to 1 of cellulose) have little or no influence on the formation of sulphuric esters.

(3) The following results, averaged from a large number of experiments, show that within the limits of 4 to 8 per

* For details of method see this J., 1905, 376.

cent., the water contents of the acid mixtures have practically no effect on the product.

Acid mixture.		In product.	
Water.	Proportion H_2SO_4 HNO_3	Combined sulphuric acid.	Nitrogen.
Per cent.		Per cent.	Per cent.
4	3/1	0.08	13.7
7	3/1	1.00	13.6
8	3/1	1.01	13.5

These results are confirmed by all our experiments, both with cellulose in different physical conditions, and with acids in other proportions than 3/1.

Before discussing the effects of the proportions of the two acids in the mixture, the physical condition of the cellulose, and the time of contact, it will be convenient to consider the action of concentrated sulphuric and nitric acids separately in contact with cellulose. Sulphuric acid rapidly attacks and dissolves cellulose, forming soluble cellulose sulphates. On standing, the solution blackens more or less rapidly, giving evidence of breaking up of the cellulose molecule. The gradual hydrolysis of these esters, dextrose being the ultimate product, has been investigated by A. L. Stern. Concentrated nitric acid, on the other hand, rapidly forms insoluble nitrates, the degree of nitration depending on the concentration of the nitric acid. The maximum degree of nitration attainable by the nitric acid used is reached after a few minutes' contact; the product is found to be highly parchmentised and readily stabilised by boiling with water.

Our experiments show that, when the two acids are mixed, and are in contact with cellulose, each acid endeavours to carry out its characteristic function, the sulphuric acid to dissolve, and the nitric acid to form nitrates, not readily attacked, when once formed, by the sulphuric acid in the mixture. The acids in the mixture exert a mutual checking or retarding influence; in fact, each may be looked upon as a diluent. The sulphuric acid (considered apart from its dehydrating action), delays nitration, and the nitric acid checks the solvent action of the sulphuric acid. The quantity of combined sulphuric acid found in the product depends on the extent to which each of the acids has been able to exert its influence. It must be borne in mind, however, that of the two acids, nitric shows far more reactivity with cellulose, the ester-forming reaction proceeds with much greater velocity, and the resulting nitrates are comparatively inert as regards further action of mixed acids. They are insoluble, both in nitric acid and in acid mixtures containing large proportions of sulphuric acid. On the other hand, the solvent action of sulphuric acid is not only intrinsically slower than the action of nitration by nitric acid, but produces a condition (solution) which is readily susceptible to further chemical changes.

(4) *Relative proportions of sulphuric and nitric acids in the nitrating mixture.*—Table I. gives the results obtained by immersing cellulose in mixtures containing various proportions of sulphuric and nitric acids. The experiments were made with Swedish filter paper. The excess of acid mixture used in each experiment in Sections A, B, and C was such, that not less than 12.5 parts by weight of nitric acid were present to each part of cellulose. The third and fourth columns give the results of determinations of the degree of nitration and percentage of sulphuric acid combined in the products.

TABLE I.

Section.	Acids H_2SO_4 HNO_3	Time of contact with acids.	Product.		Remarks.
			Nitrogen.	Combined sulphuric acid.	
	Nitric acid alone	—	Per cent. 9.6 to 13.5	Per cent. —	
A.	1/3	1 hour	13.70	0.27	Strongly parchmentised. Degree of nitration varies between wide limits according to concentration of nitric acid. Nitration complete in few minutes.
		1 hour	12.64	0.79	Strongly parchmentised.
		5 minutes	10.69	0.01	Parchmentised. Yield, 178 per cent.
	3/1	15 minutes	12.84	0.08	Slightly parchmentised. Not broken up.
		30 minutes	13.20	0.08	2.5 per cent. soluble in 98 per cent. alcohol.
		1 hour	13.55	1.01	Yield, 178 per cent.
B.	5/1	6 hours	13.48	1.96	Unchanged in appearance. 4.3 per cent. soluble in 98 per cent. alcohol.
		3 days	13.53	1.60	Unchanged in appearance. 3.9 per cent. soluble in 98 per cent. alcohol.
		10 days	12.55	1.75	Unchanged in appearance.
		41 days	13.60	1.56	Broke up on washing.
	6/1	6 hours	12.87	2.42	Soft, not broken up. 6.1 per cent. soluble in alcohol.
		3 days	12.41	1.77	Broke up on washing. 5.9 per cent. soluble in alcohol.
		10 days	13.53	1.63	Broke up on washing.
		41 days	13.65	1.85	Broke up on shaking in mixed acids.
	8/1	6 hours	10.72	4.33	Soft, broke up on washing. 12.9 per cent. soluble in alcohol.
		3 days	12.56	2.68	Broke up in nitrating acids. 12.7 per cent. soluble in alcohol.
		10 days	13.31	2.03	Broke up in nitrating acids.
		41 days	13.40	2.10	Broke up to fine powder on washing. Yield, 50 per cent. approximately.
C.	10/1	3 hours	7.41	6.46	Soft, broke up on washing.
		6 hours	10.02	6.58	Soft, broke up on washing. Yield, 162 per cent.
		3 days	11.59	4.48	Broke up in acid mixture. Yield, 130 per cent.
		6 days	11.63	4.23	Much broken up in acids. Yield, 67 per cent. approximately.
	12/1	3 hours	—	—	Breaks up into powder on washing.
		6 hours	—	—	Cellulose broken up.
		3 days	—	—	Cellulose partially dissolved.
		6 days	—	—	Solution nearly complete.
	15/1	3 hours	—	—	Solution complete.
		6 hours	—	—	Solution nearly complete.
		3 days	—	—	Dissolved, solution not quite clear.
		6 days	—	—	Clear solution, no charring.
D.	19/1	1 hour	—	—	Complete solution in 1 hour, no charring.
	38/1	30 minutes	—	—	Complete solution in 30 minutes, charred on standing.
	H_2SO_4	20 minutes	—	—	Complete solution in 20 minutes, slight charring.

All the phenomena attending the reaction of nitration are characterised by their progressive nature; the results show a gradual change in the reaction, from rapid nitration with high yields in Section A, through stages of delayed nitration with increasing solution of the cellulose, until the solvent power of the sulphuric acid predominates, and the material goes into solution. Progressive action is further shown by the physical condition of the products. Cellulose nitrates made with nitric acid alone, or with acid mixtures containing relatively large proportions of nitric acid, are much hardened and parchmentised. This hardening effect takes place immediately on immersion in the acid, and not, as in the process of parchmentising with sulphuric acid, only on washing. It is probable that these products consist of cellulose not only nitrated, but also hydrated. Further investigation may show that when the proportion of sulphuric acid present is small, water enters into the composition of the product. We have also observed that the products of nitration with acid mixtures containing from 16 to 21 per cent. water are similarly hardened and parchmentised.

Lunge ("Researches on nitrocellulose," J. Amer. Chem. Soc., 1901, 23, 527) observed that, when the proportion of sulphuric acid in the mixture exceeds 7/1 the product breaks up into a fine powder on drying. He also found that nitration with 3/1 acids, but at temperatures from 60°–80° C., gave similar products. We would suggest that the effect is due to the same cause in both cases, *viz.*, to increased solvent action by the sulphuric acid, brought about in the one case by its excess in quantity, and in the other case by its increased solvent power at raised temperatures. The greater reactivity of nitric acid is shown by the fact that the retarding influence of excess of sulphuric acid is not apparent to any great extent until the proportion 6/1 is reached; even the mixture 10/1 has primarily a nitrating action. On the other hand, a comparatively small proportion of nitric acid is capable of delaying considerably the solvent power of sulphuric acid.

proportion of sulphuric acid (Section B), an excessive quantity of mixed ester is first formed; this excess is, however, reduced by the action of the nitric acid until in each acid mixture an equilibrium is reached when no further SO_4 groups are replaced by NO_3 . At the same time, the yield diminishes as the proportion of sulphuric acid in the mixture is increased. These actions are progressive, and indicate that while the action of the nitric acid is delayed, sulphuric acid is enabled to act on the cellulose, tending to form soluble sulphuric esters.

The question now arises whether mixed esters are formed by the complete solution of part of the cellulose in sulphuric acid, and subsequent precipitation within the material by the addition or substitution of NO_3 radicals. In order to test this theory, cellulose was allowed to dissolve completely in sulphuric acid, and this solution was then mixed with nitric acid. The addition of nitric acid was made by two methods, *viz.* :—

(a) By adding the sulphuric acid solution gradually to excess of nitric acid; and

(b) By gradually adding concentrated nitric acid to the sulphuric acid solution. By both methods precipitates are obtained; they have similar properties, but these are in no way characteristic of mixed esters. The product consists of an amorphous powder containing from 14–15 per cent. nitrogen and 0.5 per cent. sulphuric acid.*

The conditions favourable to the formation of mixed esters were then sought for at a stage of the reaction before complete solution. It was found that a condition of partial solution or gelatinisation of the cellulose by sulphuric acid is most favourable to the formation of mixed esters. The following experiments (Table II.) show the products obtained by allowing concentrated sulphuric acid to act first on cellulose for various times, and then placing the cellulose, saturated with sulphuric acid and in a state of semi-solution, into a nitrating acid, either nitric acid alone, or a mixture of sulphuric and nitric acids, for various periods.

	(6) Dipped in sulphuric acid 30 seconds, drained $1\frac{1}{2}$ hours.	Nitric acid	1 hour	10.56	1.3

It will be seen that sulphuric acid is combined in all the products of nitration with mixtures of sulphuric and nitric acids, and that the amount of mixed ester formed, other conditions being equal, is determined by the proportions of the acids in the mixture acting on the cellulose. When the proportion of nitric acid in the mixture is sufficient to ensure rapid nitration, the cellulose is immediately protected from the solvent action of the sulphuric acid, by conversion into nitrate.

The results given in Section A are directly contrary to the theory of the "pioneering" action of sulphuric acid; that is, that the first action consists in the conversion of the cellulose into sulphate, and that nitric acid subsequently replaces sulphuric acid in the ester. Section A shows the formation of sulphuric esters side by side with nitration. It will be observed that by increasing the

The results detailed in Table II. point to the conclusion that partial solution of the cellulose and "fixation" of the product by substitution of nitric acid radicals are the stages through which mixed esters are formed.

(5) *Physical condition of the cellulose.*—Under the same conditions of nitration, cellulose in different physical forms gives nitrated products varying in composition.

In the following series of experiments, five forms of cellulose were nitrated, namely:—(1) Cotton wool; (2) Washed cops; (3) Swedish filter paper; (4) Filter paper issued by the Home Office for the use in making heat test paper; (5) A thick filter paper. Samples of

* This substance will form the subject of a separate note.

each of these forms of cellulose nitrated for one hour in 3/1 acid mixture, gave the following products:—

TABLE III.

Form of cellulose.	Product.	
	Nitrogen.	Combined sulphuric acid.
	Per cent.	Per cent.
1. Cotton wool	13.75	0.70
2. Washed cops	13.75	0.73
3. Swedish filter paper.....	13.35	1.01
4. Heat test paper	13.38	1.53
5. Thick paper	12.52	2.58

From the results given in Table I. we may conclude that these variations are due to the fact that the acid mixture acting on the cellulose is not the same in each case, but the proportion of sulphuric acid acting is least in sample (1), and greatest in sample (5), and this, although the bulk of the acid mixture used was identical in composition in every case. The notable difference in physical condition of the five samples is one of density of the material. The surface of cellulose exposed to the action of the acids is greatest in cotton wool, and less in each succeeding sample. In the case of the three papers (3), (4), and (5), the relative densities were determined, taking Swedish filter paper as a standard, with density = 1. Equal areas of the three papers were taken, their average thicknesses found, and the equal areas weighed. In this way it was found that sample (4) has a density of 1.22, and sample (5) a density of 1.52, when compared with sample (3). This increase in density leads, when the papers are immersed in a nitrating mixture, to concentration of sulphuric acid in the absorbing material. Two explanations suggest themselves:—(a) That sulphuric acid is, in itself, able to penetrate and occupy the spaces between the particles more easily than nitric acid (selective action); or (b) that the mixed acids absorbed at first may be in the proportions in which the acids were made up in the mixture (no selective action): but nitric acid is continually being removed by combination with cellulose from the mixture absorbed; thus the proportion of

considered independently of the bulk. The greater the quantity of acid mixture in contact with unit weight of cellulose, the more rapid is the nitration, and the less the effect from partial solution by sulphuric acid. The conditions are evidently most favourable in the case of cotton wool; a large surface is presented to the action of the acids and the minimum of sulphuric acid is found combined. In the case of the papers, samples (3), (4), and (5), above, the amount of acid absorbed per unit weight of cellulose decreases with the increase in density of the paper, the acid mixture becomes richer in sulphuric acid, and delayed nitration and partial solution lead to increase in the combined sulphuric acid.

That the difference in the products obtained by nitrating these three papers under the same conditions is due only to the physical condition of the samples, was shown by the following experiment. A sample of each of the papers was pulped by shaking up for some time with warm water; the water was drained off on a Büchner filter funnel and the cellulose in the funnel pressed gently, so that in each case a layer of cellulose was obtained of about one-fifth inch thickness. Each sample was then nitrated under the same conditions, and the combined sulphuric acid in the products determined. The results were:—

	Combined sulphuric acid.
	Per cent.
Swedish filter paper	1.42
Heat test filter paper	1.45
Thick filter paper	1.44

(6) *Time of contact between cellulose and acids.*—In considering the results given in Table I. above, it has been shown that the extent to which sulphuric esters are formed depends mainly on the proportions of the acids in the mixture. The action being progressive, the amount of combined sulphuric acid and the degree of nitration vary at different stages of time of contact. In Table I. the proportions of acids in the mixture and the time of contact were varied, the physical condition of the cellulose being the same in all cases. In Table III. the physical condition of the cellulose is the variant, the proportions of acids in the mixture and the time of contact being constant.

In the following experiments (Table IV.) the time of contact and the physical condition of the cellulose are the variants, the proportions of the acids in the mixture being constant (3/1 in all cases).

These results show that as the density of the material increases, there is a general tendency towards slower

sulphuric acid in contact with the cellulose for the time being is increased. The latter view is found to be in accordance with the facts. The bulk of the acid mixture in the nitrating vessel may be considered as non-reactive, serving only as a reservoir or acid supply: the acid mixture actually in contact with the cellulose being

nitration, and increase in the proportion of sulphuric acid combined in the product. In Table I., where the physical condition of the cellulose was the same in all cases, the same result was arrived at by increasing the proportion of sulphuric acid in the mixture, as will be seen in the following table:—

TABLE V.

Cellulose nitrated.	Acids.	Time.	Nitrogen.	Sulphuric acid.
			Per cent.	Per cent.
Thick filter paper....	3/1	1 hour	12.52	2.6
Swedish filter paper }	6/1	6 hours	12.87	2.4
	8/1	3 days	12.56	2.7

The proportions of the acids acting on the cellulose determine the rate of nitration and the consequent formation of sulphuric esters; therefore the proportions of the acids acting on the cellulose in the experiments given in Table IV. cannot be the same in all cases.

An attempt was made to estimate the proportions of sulphuric and nitric acids in contact with cellulose while nitration is proceeding. Samples of Swedish and thick filter papers were cut into circular pieces about 1 inch in diameter. Several of these pieces were immersed in 3/1 acid mixture for given times. The nitrated papers were removed from the acid bath, and pressed gently on blotting paper to remove the acids adhering to the surface. The papers, now containing only the acids actually absorbed and acting on the cellulose, were washed free from acid in distilled water. The ratio, sulphuric acid/nitric acid, in the acids washed out was estimated: the total acid being found by titration with *N*/50 alkali, and the proportion of sulphuric acid by weighing as barium sulphate. The degree of nitration of the products was also determined. The result of this series of experiments is given in Table VI. The figures represent the average of a large number of experiments.

These results show that the denser material is not capable of absorbing the same weight of mixed acids per unit weight of cellulose as the less dense material. It follows that as the nitric acid is removed by combination,

no sulphuric acid was combined with the nitro-cotton, which was contrary to expectation. The other fact was, that with an impure paper like Swedish filter paper, a percentage of nitrogen resulted higher than was foreseen by Lunge, who found 13.80 per cent. and whose guncotton at that percentage was unstable. The authors had 13.96 as the maximum, and one began to think that a theoretical nitrocellulose could be reached, at any rate in a laboratory. He did not know whether these percentages of nitrogen had been found before properly washing and stabilising. He expected that a good deal of combined sulphuric acid was thereby removed, and the mere fact that such removal took place was interesting, inasmuch as it showed that the percentages of nitrogen might be incorrect. Whilst the authors had found a number of interesting data, they were nevertheless mostly obvious facts, obvious in this sense, that when 38 parts of sulphuric acid to one of nitric acid were taken, and they were told that the quantity of nitric acid was in all cases 12, one part of cotton must have been nitrated in something like 456 parts of acid, out of which 444 parts were sulphuric acid. Under such conditions it was not surprising that the sulphuric acid had a preponderant action. If the authors had kept to the same quantity of acid and varied the proportion of nitric acid to sulphuric acid the results might perhaps be a little more comparable; as they were, they gave the obvious result that the more sulphuric acid used, the larger was the quantity of mixed acid, and the more the cellulose was dissolved, until ultimately solution was complete. On the other hand, with a large excess of sulphuric acid, a large quantity of combined sulphuric acid was to be expected, and then, by longer exposure to nitration the nitric acid would displace the sulphuric acid.

Dr. R. ROBERTSON said the previous paper by Messrs. Hake and Lewis had proved useful to those engaged in the manufacture and stabilising of guncotton, and in the same way they might gain much interesting information from this one. From Table I, it appeared that as the

the mixture becomes rich in sulphuric acid, and these conditions, favourable to the formation of sulphuric esters, prevail until equilibrium is slowly reached.

SUMMARY.

1.—Sulphuric acid is found to be combined in all products of nitration with acid mixtures containing sulphuric acid.

2.—The formation of mixed esters is due to delayed nitration, partial solution or gelatinisation of the cellulose by sulphuric acid, and subsequent fixation by nitric acid.

3.—The amount of sulphuric ester formed is determined by the proportion of sulphuric and nitric acids acting on the cellulose during nitration.

4.—The proportions of the acids acting on the cellulose during nitration is determined by the density of the material.

Our best thanks are due to Mr. N. K. S. Brodribb for his assistance in carrying out the numerous determinations made in connection with this investigation.

DISCUSSION.

Mr. OSCAR GUTTMANN said they had learned two important facts from the paper, one, that in nitration with nitric acid alone and precipitation with sulphuric acid,

concentration of sulphuric acid in the mixed acids was increased, a greater proportion of sulphuric acid esters in the product was obtained. In section A of Table I, where the proportion of sulphuric acid to nitric acid was still normal, and similar to what one would use in making guncotton, it was found, as time went on that there was no increase in the proportion of sulphuric esters. In Section B, however, a considerable increase was obtained at first, followed by a decreasing proportion until an equilibrium was reached. He gathered that the authors held the view that, instead of the "pioneering" action of sulphuric acid, of which there is no evidence within the range of results shown in Section A, though it might perhaps be said to occur in Section B, the sulphuric acid acted by a process of solution producing a condition of the cellulose favouring the introduction of nitric and sulphuric acid residues. Instead of assuming that the mechanism of the reaction would run in the sense of sulphation followed by an elimination of nearly all the sulphuric acid residues by nitric acid residues, it would seem reasonable to assume that the action of the mixed acids on cellulose would depend on three things: the active masses of the two acids, their relative avidities for cellulose and their relative rates of esterification. The active masses were known, the avidity of the nitric acid for cellulose

was obviously, from the nature of the product, extremely high, but on the subject of the relative rates of esterification there would appear to be some difference of opinion. The authors made the remark that the rate of nitrification is high, while that of solution is low. It might very well be, however, that the rate of sulphation is fairly high, for the authors have shown that when cellulose is dipped for only a few seconds in sulphuric acid and then transferred to a nitrating mixture, a large proportion of sulphuric ester is formed, and also if one took cotton wool, dipped it momentarily into sulphuric acid and washed quickly, the product contained a large quantity of the same body. Thus one might assume the rate of esterification of sulphuric acid to be fairly high. If it were, such a result as that shown in Section B of Table I would seem to be explained. In the first place, the high content of sulphuric acid was due to the large active mass of acid present, and in the second, the gradual tendency towards an equilibrium and lowering of the sulphuric acid content would be due to a disturbance of the equilibrium by the greater avidity of nitric acid; so that this hypothesis seemed to him equally tenable. With regard to the presence of these esters, this paper was certainly important because it would indicate to the manufacturer what to avoid in choosing a nitrating mixture and it might very well account for the superior quality of the guncotton made by the displacement process, in which the nitrating mixture contained over 20 per cent. of nitric acid, while in the Abel process the guncotton was for many hours in contact with an acid containing not much more than 10 per cent. Fortunately there was little difficulty, with a proper method of boiling, in getting rid of these sulphuric acid esters. In an acid solution they readily broke down, and there was no practical difficulty in detecting them. On subjecting guncotton containing these esters to any heating-up test, the presence of a non-volatile catalyser very readily produced a marked evolution of gas, and an extraordinary high evolution in the Will test, mentioned by him on a previous occasion (this Journal, 1901, 21, 820), was due simply to the presence of about 0.7 per cent. of sulphuric acid ester.

Mr. W. RINTOUL said whether the sulphuric ester was formed side by side with the nitric ester or not, was not quite clear: as Dr. Robertson had said, Table I afforded evidence either way. Section A showed that with 3/1 acid, the sulphuric acid ester was a constant, but in Section B there was distinct evidence of a decreasing amount being found with the increase of time. It looked there as if the sulphuric ester was broken down by the nitric acid with the formation of nitric esters. It had been suggested by Haessermann (*Z. Ges. Schiess-u. Sprengstoffwesen*, 1908, 3, 121), that, in the formation of the lower cellulose nitrates, the production of addition compounds between the nitric acid and the cellulose constituted one step in the reaction of nitration. It was possible that a similar and intermediate formation of addition compounds occurred during the production of the higher nitrates from mixed acids. This hypothesis would explain the abnormally high nitrogen contents quoted in some of the tables, as the nitrocelluloses examined had been only very slightly washed. The test of two hours' standing which had been applied was not sufficiently drastic to prove that no more acid could be removed by cold washing. His own experience had been that, if the washing were prolonged this point of first neutrality, sulphuric and nitric acids were removed in equal quantities. Another difficulty had occurred to him in trying to account for the sulphuric acid present in guncotton, namely, that on boiling nitrocellulose until a state of thorough stability was reached there still remained a small proportion of sulphuric acid organically combined. If this residue were present as an ester, as in the cold washed nitrocelluloses containing high proportions of sulphuric acid, it ought to be possible to remove it, but he did not think any method had yet been found whereby guncotton absolutely free from organically combined sulphuric acid could be produced from mixed nitric and sulphuric acids. Although their knowledge of the subject was considerably advanced by the present paper, there still remained many points in relation to the nitration of cellulose which required elucidation.

Mr. W. F. REID said the whole series of experiments was practically made on a material, Swedish filter paper, which was, to begin with, quite indefinite, but which the authors assumed to be pure cellulose. Then there was another material called "thick paper" upon which they had no information at all; therefore for him the only practical interest centered in Table 3, where materials were used which were of practical importance. Another point which affected the whole of this series of experiments was that the method of treating the material produced was totally different from that which had been found necessary in practice. It had been washed cold, and they knew that if they washed such bodies cold, they did not get the same result as if they washed it hot. The product was dependent on a variety of circumstances which were not represented in these Tables in any way at all. He did not wish to criticise a very interesting work too much, but some things which were well known many years ago were given as the result of these experiments. For instance it was thoroughly well known that the state of sub-division of the material was important. Von Lenk had shown that, if not some one earlier. Certainly in the guncotton industry it was found many years ago that they could only use cotton waste, when carded and finely subdivided. The industry therefore had been based on a fact which was one of those supposed to be brought out in this paper. Again, with regard to the action of a mixture containing a large quantity of sulphuric acid, as compared with one containing a smaller proportion, it was very clear that mass action had something to do with the ultimate product. He thought the question was not only one of nitration, but there might be denitration taking place, which ought to have been gone into. When nitro-products were exposed to the action of a large bulk of sulphuric acid for a long time, a certain degree of denitration took place.

Captain M. B. LLOYD said Dr. Robertson seemed to have missed a point in Table I, Section B, viz., the question of yield. He was referring to the way in which the sulphuric acid esters were diminished with time, but was not that due to the increased quantities taken up in the solution rather than to the sulphuric acid esters being turned into nitric acid esters? There was the total yield given at the bottom, but it was rather a pity, from his point of view, that there was not a column of yields corresponding to each time of nitration. The yield for 41 days was only 50 per cent., and therefore a very large percentage of sulphuric acid esters was probably taken into solution. In Table C there was given the 3-days and 6-hours yield; the 6-hours yield of cellulose was 162 and the 3-days 130, showing that the yield continually diminished the whole time, for which allowance must be made in considering the quantity of esters. With regard to Mr. Reid's criticism he thought the authors' intention was rather to investigate the process of nitration than to present figures which would be of use in estimating the finished product, and therefore it was important that the products should not have been boiled and reduced to their finished state, because in that condition, as was well known, the greater part of these organic esters would have been removed.

Mr. G. W. MACDONALD, replying on behalf of the authors, said, with regard to the "pioneer" theory put forward by Messrs. Cross and Bevan (*Berichte*, 1901, 34, 2496), it should be pointed out that they were working with a 3 to 1 ratio of sulphuric to nitric acid. The authors' results, when using this same ratio, show this theory to be incorrect. Lunge stated that, using strong nitric acid to nitrate cellulose, the maximum obtainable was 12.78 per cent. of nitrogen. The percentage of nitrogen (13.5) found by the authors in similar conditions, was not affected by boiling till stable. It should be noted that the analyses were carried out on the cold-washed products. They had not been stabilised. As Captain Lloyd pointed out, the mechanism of the reaction was what the authors were investigating, and that was undoubtedly of great value from the manufacturing point of view. As guncotton was not manufactured in Australia the authors were at rather a disadvantage in not being able to obtain confirmation of their results on the large scale. They thought, however, that the results showed, among other things, that homogeneity of material, fineness

of division, absence of knots or cellulose hardened by chemical treatment, and reduction of sulphuric acid in the mixture to the minimum consistent with economy of production are obvious advantages. The speaker considered that the authors' results were largely confirmed from the manufacturing point of view, seeing that the amount of sulphuric acid fixed, in the normal course of manufacture, was about 1 per cent. On stabilising this amount greatly diminished, and Mr. Chrystall, who had devoted a good deal of attention to this point, had found in 6 different samples of gun-cotton of current manufacture percentage of combined sulphuric acid varying from 0.09 to 0.30. He agreed with Mr. Rintoul that there was no nitro-cotton manufactured on the large scale which was free from combined sulphuric acid—somewhere about 0.2 per cent. The same remark applied to collodion cotton, even though in that case the nitro-cotton was probably prepared with a less ratio of sulphuric acid to nitric acid in the mixed acid.

Mr. A. E. LEIGHTON wrote: "The appearance of this paper is most opportune in view of the revival of interest in the direct dipping process for the manufacture of nitro-cellulose consequent on the invention of the Waltham Abbey displacement process. However inviting a new process of nitration may be on economical considerations, the stability and quality of the product is of the first importance, and there appears to be little doubt that the stability of nitrocellulose, and especially of mixtures of nitroglycerin and nitrocellulose, is gravely affected by the presence of combined sulphuric acid in the nitro-cellulose. The authors' research, permitting as it does of estimating the effect of composition of the nitrating acids, the nature of the cellulose and time of nitration on the formation of cellulose sulphuric esters, is of great value. There can be no doubt, as judged by modern stability tests, that the elimination of the combined sulphuric acid from nitrocellulose, is attended by an improvement in the stability of mixtures of nitroglycerin and nitrocellulose. In the discussion on Hake and Lewis' paper (this J., 1905, 380), Dr. Robertson pointed out how readily nitroglycerin reacted with "stabilised" nitrocellulose and how valuable was the paste test as an indication of the quality of the nitrocellulose ingredient. This reactivity of nitroglycerin with "stabilised" nitro-cellulose assumes the greater importance the longer the mixture of nitroglycerin and nitrocellulose is to be stored. It may be that existing purification processes for the nitrocellulose used in blasting explosives, which are not usually stored for prolonged periods, meet all requirements, and yet be faulty where the nitrocellulose is to be used in a nitroglycerin-nitrocellulose propellant, which may be called on to withstand drastic storage conditions for many years. Further bearing on this question is the fact that the slow decomposition of nitrocellulose gives rise to fatty acids, and such acids will therefore be produced on prolonged storage of a nitroglycerin-nitrocellulose powder. The exact significance of this slow decomposition becomes clear by the experiments on the effect of acetic acid vapour on cellulose sulphuric ester recorded in the research by Hake and Lewis (this J., 1905, 374), and points to the possible production of free sulphuric acid in nitroglycerin-nitrocellulose powders when the latter are stored under conditions favouring decomposition. It must be admitted that even the possibility of free sulphuric being produced in a powder should be avoided, and it seems that the total elimination of combined sulphuric acid from the nitrocellulose is the result to be aimed at. However, it appears to be much easier to obtain cellulose sulphuric esters than to remove them, when once formed, by the ordinary process of stabilisation, and it is therefore of importance that the process of acid treatment should fix the minimum of sulphuric acid on the cellulose. It is here that the authors' work is of great value to anyone brought face to face with the problem of substituting a new process of nitration for an old, thoroughly-tried process such as the Abel, for it is no light matter to throw over a process producing nitrocellulose which has withstood successfully the climatic trial of thirty years. In my opinion, it is not sufficient to say that two nitrocelluloses of exactly similar ultimate composition will have equal stability under similar storage conditions, for the one may

have entered on its stabilisation treatment containing much more combined sulphuric acid than the other, and it is not probable that the elimination of this sulphuric acid can be brought about without straining the ester in some particular direction, and possibly conferring added reactivity with nitroglycerin. Fortunately the work of the authors makes it clear that such a change of method of acid treatment as that from the Abel process to the Waltham Abbey displacement process, will not have the effect of forming a mixed ester containing more sulphuric acid, or one less susceptible to stabilising treatment, for the authors show with acids mixed in the proportion of three of sulphuric acid to one of nitric acid, that temperature of nitration and variations in the excess of nitrating acids to cellulose, have little or no influence on the formation of sulphuric esters. Turning to Table III. it is interesting to note the authors' experience with cellulose materials of varying degree of compactness, when the materials were subjected to acid treatment for a period too short to eliminate the effect of apparent density. The authors found that where there was great resistance to the free circulation of the mixed acids, nitration was delayed by reason that the acid mixture actually attacking the cellulose became richer in its proportion of sulphuric acid, with consequently increased amount of sulphuric esters in the product and a low nitrogen content. Similar experience used to be met with by the direct dipping of cellulose in pans, and where the waste acids were revived time after time. After a certain number of cycles, the acids became dirty from a cellulosic slime, which, settling on the charge of cotton waste, made it difficult for the mixed acids to find free access to the fibre, and the nitrogen content of the product was then found to be low. This trouble was accentuated by the use of cotton waste containing an undue amount of fly. Although such a difficulty is not met with where the waste acids are filtered before revivification, as occurs where the acids are drawn off slowly through the nitrated charge, the authors' results are valuable, as they draw attention to irregularities experienced under the old direct dipping process which raised some prejudice against the system. The results given in Table IV, prove that from two to three hours' immersion in mixed acids, is sufficient to eliminate any effect of the apparent density of the cellulose as affecting the final composition of the ester, and should dispel any doubt as to the suitability on chemical grounds of nitration of cellulose by a properly designed direct dipping process."

Mr. W. R. QUINAN (South Africa) writes as follows:—"In its practical application to nitrocellulose making, I regard this paper as one of the most important published in recent years. The conditions under which varying amounts of sulphuric esters appear in the nitrated product are made clear for the first time.

"It may add a little to the interest of the discussion to consider the analogy between the nitration of cellulose and the nitration of glycerin. In the manufacture of nitroglycerin, it is well known that a portion of the glycerin unites with sulphuric acid to form glycerol sulphate, thus impeding the nitration and preventing the realisation of the theoretical yield. The amount of glycerol sulphate formed increases with the percentage of sulphuric in the mixed acid. Also that time (with suitable conditions—especially low temperature) will cause a partial replacement of the combined sulphuric by nitric acid, forming additional nitroglycerin. This change takes place during cold storage of the waste acid and adds to the total yield from 2 to 8 per cent., depending upon the composition of the original nitrating mixture and proportion of glycerin used.

"There is strong evidence to show this reaction takes place wholly or partly in stages—that is, a lower form of nitroglycerin is first made, which by further action of nitric acid is changed to the highest form or nitroglycerin proper. This may be taken as an indication that the sulphuric forms more than one compound with the glycerin, but in view of its large excess in the waste acid and the readiness with which it unites with glycerin, this is not likely, and the simpler view is that for the time being, we have in this partly formed nitroglycerin a case of compound ester—a molecule in which glycerol is united with both the sulphuric and nitric acid radicle.

"An interesting question arises as to the nature of the authors' 'mixed' ester in the nitration of cellulose. Is there a compound ester present—that is, a molecule in which both sulphuric and nitric acid radicles enter—or are the respective esters complete in themselves, and only mechanically joined? One wishes that the authors had hazarded a speculation as to this. Their long and patient labours would not only give weight to their judgment, but would naturally incline them to one opinion or the other. It seems to me there are strong reasons for thinking that real compound esters are present. In the first place, the difficulty of getting rid of the sulphuric acid in purification suggests some obstacle greater than the mechanical one offered by structure after the nitrocellulose has been pulped. The term 'fixation' used by the authors implies a union which renders the ester holding the sulphuric acid, insoluble in the ordinary washing process. The complex nature of the cellulose molecule, which allows of many degrees of nitration, and the analogy with the action taking place in nitroglycerin waste acid, favour the view that in prolonged nitration, the replacement of the sulphuric radicle takes place at least partly in stages forming compound esters. This view is also confirmed by the extraordinary effect of even a small percentage of nitric acid in the mixed acid in checking the dissolving action of the sulphuric acid on the cellulose. The simplest explanation is that it enters into the composition of the molecules and makes compounds which are insoluble in the acid mixture, and as the process of maximum replacement takes a long time, while the checking action is immediate, it probably works in stages on each molecule."

Meeting held at Nottingham, on Wednesday, March 17th, 1909.

MR. O. QUIBELL IN THE CHAIR.

THE VOLUMETRIC DETERMINATION OF PHOSPHORIC ACID, MONO-ALKALI AND DI-ALKALI PHOSPHATES.

BY J. M. WILKIE.
(See this Journal, 1909, 68.)
DISCUSSION.

Mr. WILKIE said that the weakest part of the paper as published was the manner of ensuring neutrality of

the silver solution. That this solution should be neutral or at least of known acidity was vital, and a little consideration showed that that could be ensured very simply indeed. About 0.2 grm. of pure sodium chloride was dissolved in a little recently boiled and cooled water (30 c.c. or so of $N/10$ sodium chloride may be substituted if preferred) to which was added a few drops of phenolphthalein solution and one drop of $N/10$ barium hydroxide. A strong pink tint should result, which persists after adding 25 c.c. of the $N/10$ silver solution. That of course ensured that the silver solution was practically neutral. The titration was now conducted in the Jena round-bottom flasks used in the preliminary boiling to decompose carbonates and to expel carbon dioxide, thus avoiding transference to a special vessel for the titration. The end point with very little practice indeed could be readily observed, and of course any doubt was quickly dispelled by allowing the precipitate to settle for a minute or two, as the pink tint was permanent, and does not fade even after 24 hours. Finally the use of $N/5$ sodium acetate had been discontinued, and instead an equivalent amount of a $3N/2$ solution was used. This strength (20.4 per cent.) was convenient for ordinary laboratory use, and its use avoided unnecessary multiplication of solutions. In due course he hoped to publish some extensions of the method.

Mr. O. QUIBELL said that he had found the method work fairly satisfactory with acid phosphate; one difficulty was particularly noticeable, and that was the determination of the end reaction. Several determinations were made on a superphosphate containing 31.1 per cent. of water-soluble phosphates as determined by the magnesia method; 2 grms. of the original phosphate were made up to 100 c.c., and the phosphate was estimated as outlined in the paper, and the percentage found was 31.18 and 31.13. The titrations in this case were done with barium hydrate, as suggested. He saw no reason why the titration should not be done with sodium hydroxide, so several determinations were attempted in that way; but for some reason the results were extremely erratic, and he would like an explanation as to why sodium hydroxide solution is not so good as the barium hydroxide.

Mr. WILKIE replied that any difficulty as to the end point was removed by giving the precipitate a moment or two to settle. He had used sodium hydroxide in a number of titrations, and when carbonate was allowed for, excellent results were obtained. When using sodium hydroxide, his practice was to standardise in the cold against standard sulphuric acid which had been freed from carbon dioxide by boiling-working at about the same dilution as in the actual test, and of course using phenolphthalein as indicator. Barium hydroxide had the advantage of a sharper end point because of the absence of carbonate. He might again point out that decinormal sulphuric acid was the only standard solution required by the method.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—*Sd.*, each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—*1s.*, each, to the Secretary of the Society.

French.—*1 fr.*, 25 c. each, to Belin et Cie., 56, Rue des Francs Bourgeois, Paris (3c.).

German.—*1 mark* each (with full particulars) to Kaiserlich Patentamt, Berlin, Germany.

I.—PLANT, APPARATUS, AND MACHINERY.

PATENTS.

Mixing or agitating liquid compounds; Machinery for — and for other purposes. B. Skinner, Rosherville, B. J. Wilders, Westcliff-on-Sea, and E. Wilders, London. Eng. Pat. 19,347, Sept. 15, 1908. Addition to Eng. Pat. 21,160, Sept. 24, 1906 (this J., 1907, 611).

The vertical rotating cylinder described in the principal patent is made of tapering form, like an inverted truncated

cone, and is completely submerged in the liquid to be mixed or agitated. The external screw-threads may be dispensed with. For mixing water with a lighter material such as flour, the cylinder is rotated in such a direction as to cause a downward current within the cylinder. When using the apparatus to agitate a liquid for cleansing or rinsing fibrous or textile materials, these materials are placed in a perforated wood or metal chamber above the rotating cylinder, or they may be kept away from the rotating cylinder by means of a perforated screen.

—A. T. L.

Distilling and concentrating liquid mixtures; Process of simultaneously — H. Pauling, Gelsenkirchen, Germany. Eng. Pat. 27,473, Dec. 17, 1908.

THE mixture of liquids to be separated is introduced into an evaporating vessel at such a rate that it is completely vaporised. The mixed vapours are conducted into the lower part of a rectifying column into the top of which is introduced a regulated quantity of the pure liquid which forms the lowest-boiling component of the mixture. This liquid is introduced in such quantity that the vapour of the pure liquid only escapes from the top of the column. The liquid or liquids of higher boiling point are condensed in the column and escape from a siphon at the lower end. If desirable the vapours may be superheated in a coil before they enter the column.—W. H. C.

Kiln. G. E. Snowden, New Cumberland, W. Va. U.S. Pat. 916,498, March 30, 1909.

THE claim is for the construction of a kiln having a vertical flue formed in the side wall. The upper end of this flue communicates with the interior of the kiln and the lower end with an underground flue leading to the stack. Intermediate between its upper and lower ends, the vertical flue has a side branch flue which communicates with the atmosphere. A valve-box having two flap-valves is arranged in this branch, so that the kiln may be put into communication either with the underground flue or with the air as desired.—W. H. C.

Evaporator; Cast-iron — with Field tubes. G. Sauerbrey Maschinenfabr., A.-G. Ger. Pat. 207,478, Jan. 5, 1908.

IN order to avoid undue pressure on the tube-plates, *b*, of the evaporator, the cast-iron heating tubes, *a*, closed at one end, are connected to steam pipes, *d*, outside the evaporator, these latter being in communication with the steam-mains, *c*, and with pipes, *g*, for running off condensed water. The steam does not enter the heating tubes directly, but through the distributing tubes, *c*.—A. S.

Steaming and drying apparatus; Movable perforated drum in — H. Meyer. Ger. Pat. 207,483, June 26, 1908. Addition to Ger. Pat. 172,451, May 3, 1905 (this J., 1906, 1032).

THE perforated drum in which the steaming or sterilisation of the material is effected is mounted within an outer jacketed drum in which the drying is performed. Means are provided, e.g., bolts and levers, whereby the door closing the inner drum against the outer one, can be opened from outside the apparatus.—A. S.

Retaining wall for loose filtering material. S. v. Kraszewski. Ger. Pat. 207,579, May 5, 1907.

THE walls of the vessel containing the filtering material (e.g., sand), are constructed with series of lips or cups projecting outwards, and the liquid to be filtered is introduced through these lips.—A. S.

Filtering air and other gases or vapours; Apparatus for — R. Winter. Ger. Pat. 207,631, Feb. 21, 1907.

THE air or other gas is passed through a casing divided into alternate filtering-compartments and compartments into which the dust falls when brushed or setaped from the filters; both sets of compartments are disposed obliquely to the path of the air. Outside the casing, on one side, is a receptacle provided with openings communicating with the lower ends of the dust-collecting compartments. The dust falls from the latter into the receptacle and is thus prevented from being again entrained by the current of air.—A. S.

Centrifugal filter. L. Honigmann. Ger. Pat. 207,885, May 9, 1907.

THE filter consists of a hanging centrifugal basket or cage surrounded by a receptacle for the filtered liquid. The cage is closed above and opens below into a funnel-shaped chamber through which the solids are removed. The liquid to be filtered is introduced through the hollow vertical shaft of the apparatus, and falls on to a distributing plate fixed to a spindle which is movable vertically within the hollow shaft.—A. S.

Pyrometers. Norma Compagnie, G.m.b.H., Wurttemberg, and J. Kirner, Stuttgart, Germany. Eng. Pat. 27,245, Dec. 15, 1908.

SEE Fr. Pat. 395,229 of 1908; this J., 1909, 356.—T. F. B.

Filtering apparatus; Rotary — A. J. Arbuckle and A. Osborne. Fr. Pat. 395,446, Oct. 17, 1908.

SEE Eng. Pat. 20,400 of 1908; this J., 1909, 130.—T. F. B.

Filtering apparatus. A. J. Arbuckle and A. Osborne. Fr. Pat. 395,928, Nov. 3, 1908.

SEE Eng. Pat. 21,452 of 1908; this J., 1909, 195.—T. F. B.

II.—FUEL, GAS, AND LIGHT.

Natural and briquetted coal; Comparative tests of — including torpedo-boat tests, and some foreign specifications for briquetted coal. W. F. M. Goss. U.S. Geol. Survey, Bull. No. 363.

THIS bulletin contains 56 pages of matter, and a bibliographic list of works on the subject dating from 1906 to 1908 inclusive. The author describes an elaborate series of tests with natural coals and also with briquettes made from them as carried out at the testing plant of the Pennsylvania Railway Co. at Altoona, Pa., besides some preliminary experiments involving the use of briquettes, in the marine service, and carried out on the U.S. Torpedo Boat "Biddle." Illustrations and charts indicate the results obtained. The conclusions arrived at are:—I. The briquettes by the Government apparatus have well withstood exposure to weather and have suffered but little deterioration from handling. II. The use of briquettes instead of natural coal appears to have increased the evaporative efficiency of the boilers tested. III. In most cases, the smoke density has been less with briquetted coal. IV. The use of briquettes facilitates the maintenance of an even fire over the whole grate surface. V. In locomotive service, the use of briquettes results in increasing efficiency, and boiler capacity, with decreased smoke. VI. In torpedo boat service the use of briquettes improves evaporative efficiency of the boilers, but no change is noted as regards smoke.

Carbon monoxide, hydrogen, and methane; Simultaneous determination of — by fractional combustion. V. Nesmijelow. Z. anal. Chem., 1909, 48, 232—272.

THE author has studied the fractional combustion of mixtures of carbon monoxide, hydrogen, and methane by means of silver oxide, palladium-asbestos, and copper oxide respectively. No satisfactory results could be obtained with silver oxide (see this J., 1898, 603; 1899, 299); the carbon dioxide formed by the oxidation of the carbon monoxide was partly absorbed by the silver oxide

with formation of silver carbonate; also, some silver oxide was always reduced by the hydrogen as well as by the carbon monoxide. With palladium-asbestos (this J., 1903, 652) it was possible to determine carbon monoxide in a mixture of the three gases, but only if the speed of the gas through the combustion tube did not exceed 1 litre per hour. No preliminary warming of the palladium-asbestos was required. If the speed of the current of gas were unduly increased, the temperature of the contact-material was raised to such an extent that the methane also was partially oxidised. Good results were obtained in the analysis of a mixture of carbon monoxide, hydrogen, and methane by passing the gas over copper oxide heated to 250° C. (see this J., 1898, 1190), at which temperature methane was not affected, whilst hydrogen and carbon monoxide were completely oxidised.—A. S.

PATENTS.

Coke ovens. The Coke Ovens and By-Products Co., Ltd., and S. N. Wellington, London. Eng. Pat. 6223, Mar. 20, 1908.

A SERIES of regenerative, inclined coke ovens, (1), is arranged in battery form with the discharge ends of the ovens opening on to a receiver for the finished coke, the opposite ends being provided with charging doors. The side walls (2) are hollow and divided into a number of vertical main flues (3) and "intervertical" flues (4). All the flues open at the top into a common longitudinal chamber (5), which also forms the combustion chamber for a set of upper gas-nozzles (6). At the base of each of the vertical flues (3) are hot air inlets (7) and lower gas-nozzles (8). The lower gas-nozzles are divided into two series, each series being again subdivided into three sets of four nozzles, and each set supplied by a separate gas-supply pipe. Below the floor of the oven

is situated a passage (12), with which all the "intervertical" flues communicate, and below this passage and communicating with it at each end, is another passage (15). From each end of the lower passage (15) a passage leads to one of two series of regenerative tunnels, a valve governing each of these communicating passages. Passages (30) and (31) afford communication to all the air-supply passages in a manner similar to the communication given by the passages (12) and (15) with reference to the "intervertical" flues. Means are provided for connecting either series of regenerative tunnels with a main uptake flue or with the air, whereby the air supply may be reversed, so that either the upper gas-nozzles can be supplied with air, while the air-supply passages for the lower gas-nozzles serve for taking off the products of combustion, or *vice versa*.—O. R.

Coke-quenching device for horizontal coke ovens. F. J. Collin. Ger. Pat. 207,199, June 11, 1908.

THE coke-quenching box is closed on all sides and is provided with pipes for leading away the ammoniacal

vapours produced on quenching the glowing coke. Means are provided for lifting the quenching-box and transporting it from one part of the coke platform to another.—A. S.

Pyrophoric substances; Manufacture of —. Lucium-Werk, Elektro-Chem. Metall-Ind. Ges.m.b.H. Fr. Pat. 396,198, Nov. 12, 1908.

PYROPHORIC substances consisting of a rare-earth metal and silicon, titanium, or boron are manufactured by adding the silicon or other non-metal to the molten rare-earth metal out of contact with air, or by introducing the non-metal into an electrolytic cell in which the rare-earth metal is being deposited. The substances thus obtained yield sparks, by abrasion or concussion, suitable for igniting combustible gases, liquids, and even solids. The substances may also be used as flash-light powders when mixed with suitable oxidising substances.—A. T. L.

[Suction] Gas producer plant. J. King and H. Workman, Glasgow. Eng. Pat. 6191, Mar. 20, 1908.

A GAS-HOLDER of sufficient capacity to prevent the engine from slowing down when the load is suddenly increased, is interposed between the producer and the engine, and the bell is counter-weighted so as to contain gas at slightly less than atmospheric pressure. The gas-holder thus serves to draw gas through the producer, causing a continuous instead of an intermittent draught. The bell has a definite slightly fluctuating position for each rate of demand, and the rise or fall of the bell controls, by means of levers and cords, a valve on the air inlet to the producer and a valve regulating the supply of steam or the feed of water to a boiler or evaporator; or the rise and fall of the bell may control a valve regulating the proportion of air passing through the steam space of evaporator. The valves may be similar to those described in Eng. Pat. 17,414 of 1907, the area of the ports being adjustable in one direction by hand and in a direction at right-angles to the former by the movements of the bell.—A. T. L.

Gas producers. J. Stewart, Alfreton. Eng. Pat. 6204, Mar. 20, 1908.

THE patent relates to gas producers provided with grates fitted to rotate about a horizontal axis, and especially to producers fitted with grates of the kind described in Eng. Pat. 15,074 of 1906. The grates referred to comprise a drum with radial arms of different lengths which support segmental grates provided with projecting claws, the whole forming a hollow cylindrical grate, mounted eccentrically on a horizontal axis above the water-trough in the base of the producer. The invention consists in providing horizontal or inclined doors, below the level of the water in the trough, projecting inwards from the sides of the trough in order to support the fuel. The doors are hinged along the sides of the trough and can be raised or lowered to adjust the space between the grate and the inner edges of the doors, so as to regulate the discharge of ashes and the descent of the fuel.—A. T. L.

Gas producers. A. Jabs, Zurich. Eng. Pat. 13,753, June 29, 1908.

A GAS producer for caking coals comprises a producer chamber in the lower part, surmounted by a group of narrow vertical chambers through which the fresh fuel descends, meeting the hot gases from the producer chamber and being distilled by them. These distilling chambers are made wider towards the lower end to facilitate the descent of fuel, and they are charged from the feeding hopper through vertical feeding channels of smaller cross-section than the upper ends of the distilling chambers, so that an annular outlet is left for the gas at the top of each distilling chamber.—A. T. L.

Gas producer. G. C. F. Vater, St. Louis, Mo. U.S. Pat. 916,806, March 30, 1909.

A CYLINDRICAL air receptacle is mounted in the centre of a water-pan, which is situated at the bottom of the combustion chamber of the producer. An air pipe extends upwards through the air receptacle, which supports and communicates with a conical grate. The air pipe is

perforated and has its upper end closed by the apex of the cone, which is not perforated, the perforations of the air pipe being in the same horizontal plane as the grate openings.—O. R.

Ozone; Process and apparatus for the admixture of — with gases and carburetting materials for illumination and power. O. Patin. Fr. Pat. 395,804, Jan. 7, 1908.

OZONISED air is upon leaving the ozoniser, mixed with more or less ordinary air in a mixing chamber, the proportion being controlled by valves, and the mixture subsequently carburetted by gas or oil vapour and sent into the supply main. The mixing chamber may be dispensed with and the degree of ozonisation varied by increasing or decreasing the electric current producing the ozone, by means of a rheostat.—R. L.

Illuminating gas; Process for the manufacture of — by distillation of coal and admixture of a cheaper gas with the coal-gas. H. Koppers. Ger. Pat. 207,098, March 6, 1908.

COMBUSTIBLE materials (brown coals, lignites, peat) of more recent formation than ordinary coals, are carbonised in a separate furnace, the gas is subjected to the usual condensing process and also freed from a portion of its carbon dioxide, then led through a gas producer charged with coke in order to convert a further portion of its carbon dioxide into carbon monoxide, and finally mixed with coal-gas produced in the ordinary manner.—A. S.

Electric incandescent lamps; Filament for —. J. Schilling. Berlin. U.S. Pat. 917,159, April 6, 1909.

METALLIC filaments are made by mixing a finely powdered refractory substance, and a finely powdered conductor having a negative temperature coefficient, with a solution of ammonium sulphide as binding agent, so as to form a paste. The paste is formed into filaments, and the ammonium sulphide is expelled by the passage of a current. —A. T. L.

Electric incandescent lamps; Manufacture of [filaments for] — from oxides or other basic compounds of metals. J. M. Canello. Fr. Pat. 395,360, Oct. 24, 1908.

THE patent relates to the manufacture of lamp filaments from the reducible oxides or other basic compounds of refractory metals such as molybdenum, osmium, and tungsten with or without the admixture of non-reducible oxides such as the oxides of thorium and zirconium. The reducible oxide or basic compound is very finely powdered, and the heavier particles are removed by a process of repeated levigation. The extremely fine powder thus obtained is mixed with 5 to 10 per cent. of powdered gelatin, and made into a paste with water. The paste is formed into filaments, and the filaments are dried and heated to a moderate temperature in a reducing atmosphere preferably of hydrogen. The filaments are finished by heating them electrically in a reducing atmosphere and are finally mounted in exhausted lamp-bulbs into which a trace of phosphorus or other reducing substance is introduced.—A. T. L.

Electric incandescent lamps; Process for securing [metallic] filaments to the terminals in —. Bergmann-Elektricitäts-Werke Akt.-Ges. Fr. Pat. 395,482, Oct. 19, 1908.

THE ends of the filament are covered with the material of which the leading-in wires are composed, for example, platinum, silver, nickel, copper, iron, or alloys of these metals. The filament is then held in position and the ends fused on to the ends of the leading-in wires.—A. T. L.

Electric incandescent lamps; Manufacture of filaments for — from difficultly fusible metals. Bergmann-Elektricitäts-Werke Akt.-Ges. Fr. Pat. 395,484, Oct. 19, 1908.

IN the manufacture of lamp filaments from molybdenum, tungsten, chromium, uranium, tantalum, niobium, vanadium, and similar metals, the filament is heated in an atmosphere consisting of hydrogen and nitrogen or of hydrogen and ammonia, in order to render constant the electrical properties of the filaments. The invention consists in the use of illuminating gas instead of hydrogen,

the preferred proportions of nitrogen and illuminating gas being 5 to 1. The filaments are brought gradually to a reddish-white heat, and kept at that heat for 10 seconds only instead of 4 minutes as when hydrogen is used.—A. T. L.

Drying apparatus [for peat, etc.]. W. T. Griffin, Plainfield, and B. W. Tucker, Newark, N.J., Assignors to I. Pedraza, Paris. U.S. Pat. 916,437, March 30, 1909.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Acetate of lime [calcium acetate]; Analysis of commercial —. T. S. Gladding. J. Ind. and Eng. Chem., 1909, 1, 250—252.

IN the author's method, 2 grms. of the sample are treated with 30 c.c. of water and 10 c.c. of phosphoric acid of sp. gr. 1.70, and the mixture is distilled in a long-necked flask of 300 c.c. capacity for about 1½ hours, the volume being kept constant during distillation by the continuous introduction of water free from carbon dioxide. The vapours which distil over are condensed and collected in standard alkali solution. This method has been condemned by Fresenius and Grünhut (this J., 1908, 1012), but it is pointed out that in their tests, they employed a current of steam instead of introducing water into the distilling flask and thus introduced a source of error which had previously been recognised by the author and also by Grosvenor (this J., 1904, 530). The author has tested his method with solutions containing calcium acetate and phosphoric acid in varying degrees of concentration, and obtained concordant results in all cases.—A. S.

Petroleum oils; Differentiation between — of different origin. F. Schwarz. Mitt. Kgl. Materialprüfungsamt Gross-Lichterfelde West, 1909, 27, 25—28.

AMERICAN petroleum, even the most carefully refined, is characterised by its high iodine value, 6, as against 0.7—3 for European oils, and its low specific gravity, 0.788—0.802 at 15° C. Oil with a low iodine value and specific gravity above 0.815 may generally be taken as Russian, but occasionally may prove to be Roumanian or German.

Russian oils remain liquid at -20° C., whereas Roumanian (except Bustinian) and German petroleum become more or less viscous. The lighter constituents of Russian petroleum show a higher specific gravity (0.800—0.806) than those of the Roumanian or German oils (0.780—0.794). Differentiation between these last two is practically impossible, but the quantity of German oil produced is so small that nearly all is consumed locally. Oil with a low iodine value and specific gravity of 0.808—0.815 may be Galician, Roumanian, German, or Russian "Meteor" oil. The last may be recognised by the high specific gravity of the more volatile constituents, also by its higher flashing-point (30° — 37° C.). The inferior kinds of Galician oil become very viscous on cooling; the flashing-point of Galician oil is low (26° — 32° C.) as compared with Roumanian oil (31° — 34° C.) and German oil (31° — 39° C.).—A. G. L.

Mineral oil; Examination of — for fatty oil. F. Schwarz and J. Marcusson. Mitt. Kgl. Materialprüfungsamt Gross-Lichterfelde West, 1909, 27, 17—19.

In testing mineral oils for the presence of fatty oils by heating with sodium or potassium hydroxide (Lux's test), the authors contend that if appreciable quantities of fatty matter are present, both gelatinisation and formation of a soapy lather will occur. If the sample gelatinises without forming a lather, traces of fat, or rosin, or naphthenic acids may be present. In these cases the samples should be further examined. To remove mineral acid from naphthenic acids, the ethereal solution should be shaken with a concentrated solution of sodium sulphate, not with water.—A. G. L.

PATENTS.

Retort for the destructive distillation of resinous woods. P. Brown, Troy, Idaho. U.S. Pat. 917,531, April 6, 1909.

This relates to vertical retorts for a retort furnace comprising a number of vertical ovens which are open at both ends and are arranged between two spiral flues, leading from separate combustion chambers to the stack. A removable retort for each oven is provided at its upper end with a detachable cover for charging, and with a detachable gas-outlet pipe leading to a trap-box. The wood is supported on a removable grate, and the lower end of the retort is closed by a vessel secured to it beneath the grate.—A. T. L.

Wood-tar and formaldehyde; Process for making water-soluble compounds of the condensation products of —. W. P. Thompson, Liverpool. From K. A. Lingner, Dresden, Germany. Eng. Pat. 22,122, Oct. 19, 1908.

The condensation products are heated with soap, or the process of incorporation of the tar and the formaldehyde is combined with the process of "saponification." The resulting compounds are soluble in water.—W. H. C.

Ammonia from gas-liquor; Apparatus for recovering —. Berlin-Anhaltische Maschinenbau Akt.-Ges. Ger. Pat. 208,254, Mar. 31, 1908.

In the apparatus claimed, the heat of the smoke gases from the gas-retort furnace is utilised for distilling ammonia from the gas-liquor. Two chambers are built in opposite portions of the wall of the chimney of the furnace. The gas-liquor enters the lower part of one chamber, leaves near the top, flows through a connecting pipe outside the chimney to the lower part of the other chamber, and leaves this also near the top. The vapours expelled from the liquor flow out through pipes at the tops of the chambers to a reflux condenser in order to recover the ammonia.—A. S.

Impregnating material resembling coucouhou [from pitch] for mill-boards or textile materials used for covering roofs; Process for the preparation of an —. O. Schreiber. Ger. Pat. 208,378, Sept. 13, 1905.

The impregnating material is prepared from the pitch left behind in the distillation of coal-tar, petroleum, and animal or mineral products. The pitch is heated and cold

air is forced through it: during this treatment oxidising substances such as manganese dioxide, sulphuric acid, etc., and subsequently formaldehyde, are added to the mass.—A. S.

Still for distilling crude bituminous products. H. W. Asb, Cambridge, Mass., Assignor to Warren Bros. Co., Charleston, W. Va. U.S. Pat. 917,702, April 6, 1909.

The claims are for a still with means for delivering a heating blast within, and for introducing solid foreign matter into the blast-pipe so as to be carried by the blast into the still.—A. T. L.

Montan wax; Process for the purification of —. T. Asher. Ger. Pat. 207,488, Dec. 21, 1907.

The montan wax is heated twice with nitric acid of sp. gr. 1.2—1.4, then washed, and melted, whereupon, it is stated, the asphaltic or resinous matter separates and can be removed mechanically. The wax may, if necessary, be treated with bleaching liquor before being melted.—A. S.

Apparatus for determining viscosity of liquids. Ger. Pats. 205,235, etc. See XXIII.

IV.—COLOURING MATTERS AND DYESTUFFS.

Indigoid dyestuffs. IV. Indigoid and indolignoid dyestuffs of the naphthalene series and their products of fission (Hydroxynaphthaldehydes). A. Bezdik and P. Friedländer. Monatsh. Chem., 1909, 30, 271—286. (Compare this J., 1908, 398, 743.)

The authors propose a new nomenclature for the complicated indigoid dyestuffs described in this and the previous papers. Starting from the name "lignone" as being generic for the binuclear *p*-quinones, coeruleignone becomes *bis*-3 : 5-dimethoxybenzolignone,

The compound,

is *bis*-2-methoxynaphthalenelignone, whereas the isomeric substance,

is *bis*-4-methoxy-2-naphthalenelindigo. The dyestuff of the constitution,

previously described, lies between the lignoid and indigoid class and is classed as an "indolignone," being 2-indole-1-naphthalenelindolignone. 2-Indole-3-hydroxy-1-naphthalenelindolignone,

is prepared by mixing warm solutions of equimolecular quantities of 1 : 2-dihydroxynaphthalene and isatin chloride (in benzene). It forms metallic, brown needles, dissolves in hot alcohol or glacial acetic acid with a violet colour, and dyes chrome-, iron-, and alumina-mordanted cotton greenish-blue. It is especially well fixed with a cerium mordant. 5-Hydroxy-2-naphthalene-2-indole-indigo,

prepared by warming 1 : 5-dihydroxynaphthalene and α -isatinanilide with acetic anhydride, forms coppery needles which are sparingly soluble in ordinary solvents but dissolve in concentrated sulphuric acid with a blue colour. By similarly condensing 1 : 5-aminonaphthol and

1:4-acetaminonaphthol with α -isatinilide, 5-acetamino-2-indole-1-naphthaleneindigo and 4-acetamino-2-naphthalene-2-indoleindigo,

respectively are obtained as violet needles. The production of 1-hydroxy-2-naphthaldehyde by boiling 2-naphthalene-2-indoleindigo with caustic soda is described in detail, as are also similar compounds from analogous dyestuffs.—J. C. C.

Reduction of aromatic nitro-compounds by means of sodium disulphide. J. J. Blanksma. Rec. trav. chim. Pays-Bas, 1909, 28, 105—112.

Sodium disulphide may react in two different ways with aromatic nitro-compounds. If the nitro-compounds contain halogen atoms or nitro-groups rendered mobile by the presence of nitro-groups in the ortho or para positions, these mobile groups are replaced by S_2 groups, with formation of disulphides, which may easily be converted into sulphonic acids by oxidation. If the nitro-compound does not contain mobile halogen atoms or nitro-groups, reduction takes place with formation of the corresponding amino-compound and also usually a small quantity of an azoxy-compound. The results obtained by the action of an alcoholic solution of sodium disulphide on a number of nitro-compounds are given. From 5 grms. of nitrobenzene, 4.5 grms. of aniline hydrochloride were obtained. The nitro-anisols (*o*-, *m*-, and *p*-) gave yields of 70—80 per cent. of the corresponding anisidines. *m*-Bromonitrobenzene gave a good yield of *m*-bromoaniline. *m*-Chloronitrobenzene and 3,5-dichloro- and dibromo-nitrobenzene gave yields of 70 per cent. of the corresponding amino-compounds. Reduction products were also obtained from *o*- and *m*-nitrotoluene, 3,5-dinitroanisole, the 2,4-dinitro derivatives of anisole and phenol, 3,5-dinitrotoluene, and 1,3,5-trinitrobenzene. With *o*- and *p*-chloronitrobenzene, substitution products (dinitrodiphenyldisulphides) were formed in addition to reduction products, and this happened also with *o*-dinitrobenzene. In the case of *p*-nitrotoluene there were obtained *p*-toluidine and a condensation product of *p*-aminobenzaldehyde.—A. S.

PATENTS.

Azo colouring matters [dyestuffs] and intermediate products; Production of —. J. Y. Johnson. London. From Badische Anilin und Soda Fabrik, Ludwigshafen, Germany. Eng. Pat. 25,311, Nov. 24, 1908.

By treating *p*-phenylenediaminesulphonic acid with benzoyl chloride or a substitution product thereof, compounds are obtained which probably possess the constitution, $\text{X.HN.C}_6\text{H}_3(\text{SO}_3\text{H}).\text{NH}_2$, where X represents the benzoyl or substituted benzoyl residue. When these benzoyl derivatives are diazotised and combined with α -naphthol-3-sulphonic, -3:6-disulphonic, or -3:6:8-trisulphonic acid, dyestuffs are obtained which give rise to Bordeaux-red to violet-red lakes extremely fast to light. As benzoyl compounds are mentioned benzoyl, *o*-, *m*-, and *p*-nitrobenzoyl, and the chlorobenzoyl chlorides. The condensation is effected in aqueous solution in the presence of sodium carbonate, and the product is precipitated with hydrochloric acid. In the example describing the production of the azo-dyestuff, benzoyl-*p*-phenylenediaminesulphonic acid is diazotised and combined with α -naphthol-3:6-disulphonic acid in alkaline solution.—J. C. C.

Basic dyestuffs; Production of —. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 395,793, Oct. 29, 1908. Under Int. Conv., Jan. 10, 1908.

BASIC red or violet dyestuffs giving bright shades on taunin-mordanted cotton are obtained by treating salts of dinitrophenyl- or naphthyl-pyridinium or of cyano-pyridinium or substitution products with dihydroindole

or phenmorpholine or their substituted derivatives. Example 1: A mixture of 28.15 kilos. of 2:4-dinitro-pyridinium chloride, $\text{C}_{11}\text{H}_8\text{O}_4\text{N}_3\text{Cl}$, 60 kilos. of alcohol, and 26.6 kilos. of dihydro- α -methylindole,

is boiled under a reflux condenser for 4 hours. Dilute hydrochloric acid is then added and the precipitated dyestuff collected. It forms red brown needles and dyes in shades resembling those produced by Rhodamine 6G but purer and faster to light. Example 2: To a mixture of 8 kilos. of pyridine, 60 litres of alcohol, and 29.8 kilos. of methylphenmorpholine,

is added 50 litres of a solution of cyanogen bromide in ether or benzene (containing 212 grms. of cyanogen bromide per litre). The mixture becomes hot and after 1 to 2 hours dilute hydrochloric acid is added and the dyestuff collected. Brown violet needles are obtained which dye taunin-mordanted cotton in yellower shades than are produced by the preceding dyestuff.—J. C. C.

Azo-dyestuffs dyeing on a mordant. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 395,824, Oct. 30, 1908. Under Int. Conv., Feb. 19, 1908.

THE diazo-compounds of derivatives of *o*-aminophenol or *o*-aminocresol containing halogen or nitro-groups or both, but not containing sulphonic or carboxylic groups are combined with 2:3- or 2:6-dihydroxynaphthalene or with $\beta\beta$ -aminonaphthols or with alkyl or aryl derivatives of these. On chromed wool black shades are produced which are very fast to milling and light. An example is given describing the combination of diazotised 4-nitro-2-aminophenol with 2:6-dihydroxynaphthalene in alkaline solution.—J. C. C.

Azo dyestuffs dyeing cotton direct; Production of —. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 395,960, Nov. 4, 1908. Under Int. Conv., Feb. 11, 1908.

TRISAZO-DYESTUFFS are prepared by combining a diazo-derivative of the benzene or naphthalene series with an amine, diazotising the resulting aminoazo-compound and combining it with a second molecule of the same or a different amine, diazotising the aminodisazo-dyestuff and combining it with a monoacyl-*m*-diamine containing a free position para to the amino-group. The dyestuffs produced dye cotton direct in violet to blue shades, and they can be diazotised and developed with (for example) β -naphthol on the fibre, giving blue shades fast to light and washing and capable of being discharged to a pure white with hydro-sulphite. The combination of diazotised *o*-sulphanilic acid with 1-naphthylamine-6-sulphonic acid, the diazotisation of the product, combination with 1-naphthylamine-7-sulphonic acid, further diazotisation and combination with 4-acetyl-amino-2-aminoanisole, $\text{Cl}_2\text{O.C}_6\text{H}_3(\text{NH}_2).\text{NH.CO.CH}_3$, are described.—J. C. C.

o-Hydroxyazo dyestuffs; Process for preparing —. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 208,498, March 4, 1908.

SUCH derivatives of *o*-aminophenol or *o*-aminocresols as contain no sulphonic or carboxylic acid groups, are diazotised and combined with 1,3-dihydroxyquinoline. These dyestuffs give very fast red shades on chrome-mordanted wool: they can be dyed from a dye-bath which also contains the mordant, e.g., a bichromate; thus, the wool is introduced into this bath, which is heated for some time, acetic acid is added, and the bath is further heated.—T. F. B.

Mercaptans of the anthraquinone series; Process for preparing —. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 208,640, Dec. 12, 1907.

THE usual methods for converting thiocyanates into mercaptans cannot be applied to anthraquinone thiocyanates (see Ger. Pat. 206,054; this J., 1909, 239),

since hydrochloric acid has no action, and alkali hydro-sulphides reduce the -CO-groups. It is found, however, that the conversion can be brought about by means of alkalis. 10 kilos. of anthraquinone- α -thiocyanate are made into a paste with 20 litres of alcohol, and boiled under a reflux condenser with 60 litres of a 10 per cent. alcoholic solution of sodium hydroxide, until the product is soluble in water to a clear cherry-red solution: the mixture is then diluted with sufficient hot water to effect solution, filtered, and the mercaptan precipitated by addition of hydrochloric acid containing a little sulphurous acid.—T. F. B.

Thioindigo; *Process for preparing* —. Kalle und Co. Ger. Pat. 208,499, June 30, 1907.

3-KETO-2-ANILIDOBIPHENYL(1)THIONAPHTHENE, prepared by the action of primary aromatic bases on 2-dibromo-oxythionaphthene, is dissolved or suspended in alcohol or acetic acid, and hydrogen sulphide is passed through the solution until the orange-red anilide (which is soluble in benzene) has been entirely converted into thioindigo, which is very sparingly soluble in benzene.—T. F. B.

Anthracene series; *Process for preparing vat dyestuffs of the* —. Ges. f. Chem. Industrie in Basel. Ger. Pat. 208,559, May 3, 1908.

AMINO-DERIVATIVES of β -methylantraquinone are converted into vat dyestuffs by heating with alkali hydroxides in presence of oxidising agents such as lead oxide, cupric oxide, potassium chlorate, etc. Five parts of 1-amino-2-methylantraquinone, 5 parts of lead oxide, and 20 parts of potassium hydroxide are heated at 170–180° C., with stirring, for a long time. The residual dyestuff, after extraction with water and hydrochloric acid, gives a brown vat with alkali and hydrosulphite, in which cotton is dyed fast red-brown shades. Other β -methylantraquinone derivatives furnish dyestuffs giving various shades of brown.—T. F. B.

Sulphurous acid esters from pyridine and its derivatives; *Process for the preparation of* —. H. Bucherer. Ger. Pat. 208,638, Sept. 5, 1907.

SULPHUROUS acid esters are prepared from pyridine or its derivatives by heating them under a reflux condenser with excess of a bisulphite solution. Some of the homologues of pyridine behave in an analogous manner, but others do not react with bisulphite, and hence the method can be utilised for separating different constituents of a mixture of these compounds, those not converted into sulphurous acid esters being removed from the reaction-product by distillation with steam or by extraction with ether. The sulphurous acid esters are insoluble in the usual organic solvents; they are fairly resistant to acids, but are decomposed by alkalis. They are useful for the preparation of dyestuffs and as medicaments.—A. S.

1,8-Naphthylendiamine; *Manufacture of new condensation products obtained from* —. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 7575, April 6, 1908.

SEE Fr. Pat. 388,955 of 1908; this J., 1908, 975.—T. F. B.

Red dyestuffs. W. König, Dresden, Assignor to Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pat. 913,513 and 913,514, Feb. 23, 1909.

SEE Fr. Pat. 395,793 of 1908; preceding.—T. F. B.

[1:2o]dyestuffs; *Production of new mordant* —. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 395,926, Nov. 3, 1908. Under Int. Conv., March 3, 1908.

SEE Ger. Pat. 208,498 of 1908; preceding.—T. F. B.

[1:2o]dyestuff and process of making same; *Red cotton* —. R. Schüle, Frankfurt, Germany, Assignor to Cassella Color Co., New York. U.S. Pat. 912,182, Feb. 9, 1909.

SEE Eng. Pat. 2721 of 1908; this J., 1909, 304.—T. F. B.

Polyazo dyestuffs containing two mols. of aminophenyl-naphthimidozohydrozysulphonic acid or aminophenyldihydronaphthimidozohydrozysulphonic acid; *Process for preparing* —. L. Cassella und Co. Fr. Pat. 396,100, Jan. 15, 1908.

SEE Eng. Pat. 2721 of 1908; this J., 1909, 304.—T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES YARNS, AND FIBRES.

Diazotisable substantive dyestuffs; *Production of dyeings with* —. G. Friedländer. Rev. Gen. Mat. Col., 1909, 13, 97–98.

WITH this class of dyestuffs the dyeings may be produced by diazotising the colouring matter on the fibre and combining with an amine or a phenol, or the dyed material may be passed through a bath containing a diazotised amino-compound or submitted to the action of solidogene. By these means the fastness to washing is improved and the depth of the shade increased. The process, however, is somewhat long; the dyeing is carried out for three-quarters of an hour at the boil, with 3–5 per cent. of dyestuff and 25 per cent. of Glauber's salt. The material is then rinsed and treated in a bath containing 2–4 per cent. of Azophor Red and 1–2 per cent. of sodium acetate and finally rinsed and soaped. The author has found that the process may be shortened by padding in a bath containing 3–5 per cent. of dyestuff and 3–5 per cent. of Glauber's salt, squeezing, and developing directly in a dyeing machine with a solution containing 2–4 per cent. of Azophor Red and 1–2 per cent. of sodium acetate, finally rinsing and soaping. By this method, shades are obtained which are equal in depth to those obtained by dyeing by the ordinary methods.—F. M.

PATENTS.

Scouring, bleaching, dyeing, etc., of manufactured fibrous materials; *Machine for the* —. C. Hall, Eccles. Eng. Pat. 9132, May 1, 1908.

THE material may be subjected in the machine to one, two, or three operations, in a rapid and convenient manner. The main features are a tank with three compartments (the middle one being much deeper than the others), squeezing rollers fixed between the compartments, and ordinary and auxiliary batching rollers in connection with the two side tanks. Communication is provided between the two side tanks and the middle one by means of pipes with valves. Two pieces of material may be treated simultaneously in the side compartments, by running from the auxiliary batching roller through the liquor contained in the tank and on to the ordinary batching roller. Or a piece may be given two separate treatments by running from the batching roller, through the first tank and squeezing rollers, and through the liquor in the other side tank, or subjected to three operations by leading it under the guide roller in the middle tank, as well.—F. M.

Scouring wool by means of electricity; *Process and apparatus for* —. J. M. Baudot. First Addition, dated Jan. 4, 1908, to Fr. Pat. 375,237, May 8, 1906 (this J., 1907, 963).

AN improvement in the arrangement of the electrodes and the endless cloth diaphragm is described. The negative electrode is semicircular in shape and forms a perforated false bottom to the beck. The positive electrode is circular, and is fixed upon a wooden drum, mounted upon a shaft, the bearings of which are fastened to the sides of the beck. The shaft also carries the radial arms upon which the endless cloth diaphragm (carrying transverse wooden laths, with teeth), is supported. By means of differential gearing, the positive electrode and the cloth diaphragm may be rotated at different speeds, and the movement tends to keep the surface of the electrode clean.—F. M.

Cleaning fabrics; Rotary machine for —. C. Tewes, London. From "Tecza" Dampf-Fabrik chem. Reinigung und Kunst-Färberei in Krakau, Austria Hungary. Eng. Pat. 23,026, Oct. 29, 1908.

THE material to be cleaned is placed inside a washing drum, which is of open-work construction and may be revolved by means of suitable gearing. The shaft passes through stuffing-boxes in the sides of the case which surrounds the drum. This casing carries three tanks, lying parallel to the axis, for the storage of benzene, the openings between the tanks and the interior of the case being closed by valves, the spindles of which pass through the outer covers of these receptacles. The opening in the case, through which the material to be cleaned is introduced into the drum having been tightly closed, the valve of the first benzene tank is opened and the benzene allowed to flow over the goods. The outer case is held in position and the drum is slowly revolved for about 10 minutes. The outer case is then turned until the empty receptacle reaches the lowest possible point, when the used benzene drains into it; the valve is then closed and that of another tank is opened and the operations repeated with the fresh solvent. After the final washing and draining, the interior of the case is connected, by means of a pipe, with a cooling arrangement into which the vapours of the residual benzene are conducted and condensed.—F. M.

Lace; Corrodible groundwork for —. R. Bauer, Leipzig, Assignor to R. Schiller, Plauen, Germany. U.S. Pat. 917,402, April 6, 1909.

A DURABLE corrodible groundwork for lace is obtained by impregnating a material consisting of vegetable fibres with a 15 per cent. solution of aluminium sulphate, containing some colouring matter, and then drying at a temperature of 25° C. to 30° C.—S. H. H.

Weighting of silk or half silk in the form of hanks or pieces; Process for the —. F. Müller. Fr. Pat. 395,731, Oct. 28, 1908. Under Int. Conv., Sept. 23, 1908.

WHEN tin salt is employed, the weighting cannot be carried beyond a certain point without risk of damage to the fibre, the damage becoming evident during the dyeing and finishing, on storing, or in wear. The material may however be loaded to a much greater degree and without any risk of tendering, etc., by using aluminium chloride, alone or in combination with tin salt, as the weighting agent. The handle is improved by giving a final treatment with cerium chloride. The process consists of a treatment with a solution of aluminium chloride of 30° B., followed by a passage through a bath of sodium phosphate and rinsing. The operations are repeated until the desired degree of weighting is obtained.—F. M.

Union fabrics; Dyeing of —. L. Cassella und Co., Frankfurt-on-Maine, Germany. Eng. Pat. 270, Jan. 5, 1909. Under Int. Conv., Jan. 6, 1908.

CERTAIN union fabrics, such as astrachan, sealskin cloths, etc., cannot be satisfactorily dyed by the one-bath method with a mixture of substantive and acid dyestuffs in a neutral bath, owing to the injurious effect of the boiling neutral bath upon the wool. The method is rendered practicable however, by the addition of ammonium chloride, sulphate, or acetate to the dyebath; these salts dissociate as the temperature rises, and, without interfering with the dyeing of the cotton, the slight acidity produced in the bath ensures the preservation of the wool. Example. From 3 to 5 per cent. of Oxydiamine Black J E I extra conc., 3—5 per cent. of Naphthylamine Black 4B, 3—6 per cent. of ammonium chloride, and 20—30 per cent. of Glauber's salt are added to the dyebath. The material is first dyed lukewarm and then for half an hour at the boil.—F. M.

Dyeing; Process of —. Farbenfabriken vorm. F. Bayer und Co. Fr. Pat. 395,679, Oct. 26, 1908. Under Int. Conv., Oct. 1, 1908.

THE claim refers to the dyeing of half-wool, and deals with the use of substantive cotton dyestuffs, in an acid bath, for dyeing both the wool and the cotton, the wool

being brought up to shade where necessary by the addition of a suitable wool dyestuff to the bath. A number of dyestuffs which give practically solid shades are mentioned.—F. M.

Dyeing of thread on bobbins; Process for the —. J. O. Obermaier. Fr. Pat. 396,151, Nov. 10, 1908.

IN the dyeing of "cheeses," the height of which is less and the diameter greater than is usual, it has been found that owing to the differences in density between them, the inner layers do not get such a perfect treatment as the outer layers, to which the liquors obtain freer access. The fault is not obviated by filling in the spaces left between the cheeses in the dyeing vessel with a suitable material. Perfectly level dyeings are obtained however when the cheeses are arranged in a frame in which they may be subjected to a lateral mechanical pressure. In the spaces between them are placed suitably shaped wooden blocks, and the sides of the frame are then screwed up until the pressure throughout the body of the cheese is uniform. The dye-liquor therefore must penetrate evenly into the material and it is found that the dyeings obtained are quite uniform.—F. M.

Red dyeings on fibres; Process for producing —. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 207,574, May 19, 1907.

THE products formed by the oxidation of thioindigo, are reduced by alkaline reducing agents; the fibrous material is immersed in the vat thus obtained, and oxidised by exposure to the atmosphere. The dyeings are said to resemble those produced by thioindigo both as regards fastness and shade.—T. F. B.

Textile substances; Apparatus for treating — and for mixing liquids, &c. R. Diederichs. Addition, dated Oct. 26, 1908, to Fr. Pat. 390,105, May 11, 1908. (See this J., 1908, 1016).

THE space between the two concentric vessels is enlarged and now used to contain the materials under treatment; it is also provided with a perforated bottom. By this arrangement the movement of the aspirating bell in the central compartment is not impeded; it can be made to rise and fall at any desired speed.—S. H. H.

Schreiner of textile fabrics; Means for the —. W. and T. Pickles, Burnley. Eng. Pat. 10,649, May 16, 1908.

A SUPERIOR lustre and more silk-like appearance and handle are obtained by schreiner with bowls which are more or less conical in shape—the surface of the bowl being inclined to the axis. The axes of the bowls lie parallel to each other, the smaller diameter of one bowl being contiguous to the larger diameter of the other. The fabric passing between the bowls is thus subjected to a special kind of friction, which produces the superior effect.—F. M.

Resist effects; Production of — on textile fabrics. J. Y. Johnson, London. From Badische Aniline und Soda Fabrik, Ludwigshafen a. R. Eng. Pat. 12,416, June 9, 1908.

DYESTUFFS of the indigo and thioindigo classes can be resisted by printing the material with china clay in combination with acid salts or oxidising salts of copper, zinc, aluminium, etc., but the fabrics can then only be dyed in the zinc, or vitriol, dipping vat owing to the liability of the resist to be softened and removed in the alkali-hydrosulphite vat or in the mechanical or continuous dyeing machine. The resists may be employed however when dyeing with bromo-substituted indigo or thioindigo, indanthrene, etc., in a hydrosulphite vat on the jigger, or analogous machines. A white resist is prepared by mixing together 120 parts of china clay, 120 parts of water, 200 parts of 50 per cent. gum thickening, 300 parts of lead sulphate paste, 50 parts of lead sulphate powder, 100 parts of lead nitrate, and 50 parts of zinc sulphate, then boiling, and stirring well whilst cooling. A red resist is prepared by mixing 82 parts of the white resist

with 15 parts of a solution of diazotised paranitramiline and 3 parts of sodium acetate. This mixture is printed upon material which has been prepared with β -naphthol. —F. M.

"Black-red style"; Process for the manufacture of the —. O. Imray, London. From Farbw. vorm. Meister, Lucius, und Brüning, Höchst on the Maine, Germany. Eng. Pat. 12,811, June 15, 1908.

THE improved process for producing the black-red style in calico printing consists in printing diphenylamine derivatives alone or in combination with aniline or with *p*-phenylenediamine on fabrics which are prepared with β -naphthol, then developing the black by steaming for a short time, and dyeing directly in a solution of diazotised *p*-nitramiline. The black becomes pure, full and bright and the formation of light borders round the black pattern is entirely avoided. —J. C. C.

Textiles; Method of figuring —. M. Freiberger, Budapest, Hungary. Eng. Pat. 13,896, June 30, 1908.

NITRIC acid and similar compounds have been employed, printed with wooden blocks, for producing discharge effects on indigo-dyed cloth, but could not of course be used with the usual metal printing rollers. The difficulty is overcome by printing the cloth with a mixture which has no action upon the engraving of the roller, and then liberating the active principle by a subsequent treatment. Thus salts of nitric or nitrous acids may be printed, and the free acids may afterwards be liberated by treatment with acids or acid salts. Coloured discharges and combinations may be produced by incorporating suitable dyestuffs in the printing pastes. Thus to produce white, yellow, and red effects upon a blue ground, the fabric is dyed with indigo and prepared with naphthol; the white discharge is obtained by printing with zinc nitrate and formic acid, or sodium nitrate; the yellow discharge is produced by means of lead nitrate, and the red by means of sodium nitrate together with red developing or body colours. The fabric is steamed, given a short passage through sulphuric acid of 40° B., washed, and passed through a chromate solution to develop the yellow. —F. M.

Printing colours; Manufacture of permanent — and the application thereof. O. Imray, London. From Soc. of Chem. Ind. in Basle, Basle, Switzerland. Eng. Pat. 15,352, July 20, 1908.

IN printing with vat dyestuffs, the dyestuff has hitherto been incorporated in a reducing paste and printed, and the reduction and fixation have then been effected by steaming; or, the dyestuff has been reduced and the leuco derivative printed with the necessary thickening. The drawbacks incidental to these methods are overcome by mixing the dyestuff with dextrin, gum, or other thickening and then reducing with alkali hydrosulphite. The printing colour may be prepared in open vessels, as it keeps well, and the mixture may contain much less alkali than in the older methods. Steaming alone is necessary to fix the colour and the steaming may be conducted without the exclusion of air or the use of special apparatus. —F. M.

Printing of fabrics. E. Siefert-Schwab, Neunkirchen, Austria. Eng. Pat. 19,216, Sept. 12, 1908.

A SPECIAL effect is produced when the raised parts of a fabric alone are printed. The process consists in carrying the fabric in a stretched condition over the engraved roller in such a manner that it only just touches the roller. Thus only the raised parts, and particularly the weft threads (which are caused to protrude, where they intersect the warp, by the longitudinal stretching of the fabric) are able to receive the colour. To ensure perfect contact between all the intersections of the weft and warp threads and the roller, a light, elastic pressure is exerted at the back of the fabric at the place where it touches the roller. The pressure applied in an ordinary printing machine is much too great to give the desired effect, and it is stated that a foulard machine without levers and having an engraved lower roller (fitted with a

doctor and colour trough) is well adapted for the purpose. The upper roller is covered with soft indiarubber and its weight is sufficient to produce the necessary pressure. —F. M.

Designs and colour effects on textile fabrics; Production of —. J. Hübner, Cheadle Hulme, England. U.S. Pat. 917,298, April 6, 1909.

ORNAMENTAL effects are produced on textile fabrics by embossing or impressing the fabrics in the wet state after they have been treated with mercerising agents either with or without tension; and colour effects are produced on dyeing the impressed fabrics. —S. H. H.

Designs on fibrous materials; Production of —. Dr. Lövinsohn und Co. Fr. Pat. 395,609, Oct. 23, 1908.

CERTAIN aniline dyestuffs, e.g., Victoria Blue, are melted and the resulting liquid used as the printing material. A printing ink which does not dry quickly may be mixed with the melted colour. —S. H. H.

Vulcanised fibre; Manufacture of —. British Vulcanised Fibre, Ltd., and T. E. Briggs, Manchester. Eng. Pat. 6300, Mar. 21, 1908.

SUITABLE chemicals such as aluminium hydroxide or sulphate, ammonium borate or phosphate, sodium silicate, etc., are incorporated with the fibre during its manufacture, or the prepared sheets are impregnated with the salts, or coated with asbestos paint or other fireproofing composition. Fibre treated in this way is fire-resistant; it will not flame when exposed to heat but merely chars. —F. M.

Fireproof fibre and method of making same. K. P. McElroy, Washington, D.C., and C. Ellis, New York, Assignors to Fireproof Products Co., N.J. U.S. Pat. 914,300, Mar. 2, 1909.

A WAXY, non-volatile covering, insoluble in water, is given to fibrous bodies, e.g., textile materials, wood, paper, etc., by treating them with fused hexachloronaphthalene. On heating, the hexachloronaphthalene gives off vapours which retard the combustion of the material. In some cases the material is treated with a solution of a metallic salt, as in the usual fireproofing processes, sharply dried, and then treated with the hexachloronaphthalene; in this way the salt is protected from the action of water. —S. H. H.

Ramie and other fabrics; Process of rendering — water repellent and permanently colouring same without dyestuffs. A. M. Hart, London. Eng. Pat. 13,020, June 18, 1908.

RAMIE or other textile is rendered water-repellent and dyed at the same time by the following process: 3 lb. of casein are made into a homogeneous mixture with water and added to a mixture of 1 lb. of gum tragacanth with 1 lb. of water; 1 pint of sweet oil and half a pint of caustic soda (17° T.) are stirred in and then 1 lb. of dry colour (first prepared by boiling a dry pigment with water for an hour, allowing to settle, decanting the surplus water and drying the residue) mixed into a smooth paste with water is added and the whole brought with water to a volume of 2 gallons. The mixture is boiled for about an hour, stirring the whole time, and the yarns or fabrics are passed through the mixture, then between rollers into a bath of water containing 15 per cent. of alum, thence into clean water and again between rollers, being finally dried in the air. —J. C. C.

Textile materials; Removal of lye from — [after mercerising]. J. Matter, Laackon, Prussia. Eng. Pat. 7605, April 6, 1908.

SEE Fr. Pat. 392,400 of 1908; this J., 1908, 1201. —T. F. B.

Reserving woollen threads in dyeing union goods with sulphurised dyestuffs; Process for —. A. G. Bloxam, London. From Chem. Fabr. Griesheim-Elektron, Frankfurt, Germany. Eng. Pat. 22,549, Oct. 23, 1908.

Impregnating material. Ger. Pat. 208,378. See III.

VII.—ACIDS, ALKALIS, SALTS, AND NON-METALLIC ELEMENTS.

Pyrites; The increasing consumption of —, and its supply. B. Wetzig. See X.

Hydrogen peroxide; Determination of acids in —. H. Endemann. Z. angew. Chem., 1909, 22, 673—674.

DIRECT titration of hydrogen peroxide solutions in the cold with phenolphthalein as indicator gives only half the amount of acid present, and to find the whole quantity it is necessary to heat the hydrogen peroxide with excess of alkali, and then to titrate the excess with standard acid. Fifty c.c. of the sample are gently heated in a platinum basin with 10 to 15 c.c. of $N/5$ sodium hydroxide solution until evolution of oxygen has ceased, after which the liquid is cooled and titrated with $N/5$ hydrochloric acid, with phenolphthalein as indicator. For technical purposes it is sufficient to determine the amount of free acid in hydrogen peroxide solutions by direct titration in the cold, and to multiply the result by two.—C. A. M.

PATENTS.

Phosphoric acid and Glauber's salt; Process of making —. E. H. Strickler, New York. U.S. Pat. 917,502, April 6, 1909.

THE mixture of Glauber's salt and phosphoric acid, formed by digesting native calcium phosphate with sodium bisulphate solution, in combining proportions, is concentrated and the sodium sulphate separated by crystallisation. The sodium sulphate, thus obtained, is recrystallised, after adding lime to remove free acid.—F. SOEX.

Nitric acid; Manufacture of commercially pure —. Salpetersäure Ind.-Ges. First Addition, dated Nov. 2, 1908, to Fr. Pat. 374,237 of April 11, 1906. (See this J., 1906, 758; 1907, 760.)

THE mixture of gases, obtained by the process described in the principal patent, is cooled by refrigeration to a temperature somewhat above or below 0° C., according to the proportion of nitrogen peroxide present, and in this way acid of 60 per cent. strength, or over, is obtained in one operation. The concentration of the acid produced is found to increase in a marked degree, as the temperature of condensation is reduced.—F. SOEX.

[Salts of] *nitric acid; Apparatus for the manufacture of —.* G. Kettler. Fr. Pat. 396,161, Nov. 11, 1908. Under Int. Conv., Nov. 13, 1907.

THE apparatus consists of a furnace, which is heated by the combustion of a mixture of gas and air passing through it, and contains a spiral of refractory metal or porcelain, through which passes a mixture of nitrogen and oxygen. The temperature of the mixture is thus brought to 1300°—1400° C. The front part of the spiral is further heated by being enclosed in a tube, in which a mixture of benzene or other inflammable vapour and oxygen is burned, and the temperature of the gas is thus raised to about 2000° C. A further increase to 2400°—2600° C. is effected by injecting a mixture of acetylene and oxygen into the flame issuing from the spiral, or an electric arc may be disposed in front of the nozzle. The flame, which now contains nitric oxide, enters a sheet iron pipe of comparatively large rectangular section, slightly inclined in the direction of the flame, and enclosed in a vessel filled with a solution of lime or other base, which completely surrounds the pipe. In this pipe peroxidation takes place, and, when desired, the solution can be introduced as a shower through a grating arranged in the upper surface of the pipe, thus suddenly cooling the flame and absorbing the oxide with the formation of nitrate, the solution being pumped back into the vessel until neutralised. A special opening is provided for observing the flame as it leaves the spiral.—F. SOEX.

Sulphuric acid; Simultaneous manufacture, concentration, and purification of —. G. C. de Briailles. First Addition, dated Oct. 19, 1908, to Fr. Pat. 393,665 of Oct. 31, 1907. (See this J., 1909, 139.)

THE addition relates to an improved apparatus for realising the process described in the principle patent. A stoneware vessel encloses a porous pot in which is the anode of platinum wire; granules of retort carbon or coke and antimonial lead are packed outside the porous pot and surround a rod of antimonial lead which acts as the cathode. The vessel is closed, gas-tight, by a stoneware cover, and a mixture of liquid sulphurous acid and sulphuric acid (45° B.) is introduced. Sulphuric acid is produced at the anode and becomes more and more concentrated as electrolysis proceeds, and hydrogen or pure sulphur, according to the voltage, is liberated at the cathode.—F. SOEX.

Sulphuric acid; Construction of lead chambers for the manufacture of —. R. Moritz. Fr. Pat. 395,694, Oct. 26, 1908.

INSTEAD of the closely attached wooden framework generally employed for supporting sulphuric acid chambers, it is proposed to adopt a stout external suspending frame, not in direct contact with the lead chamber. The walls of the chamber are attached, by a series of projecting leaden strips, each extending from top to bottom, to fairly rigid iron tie-rods hanging from the external roof and attached below to the sheet-iron casing round the floor of the chamber. The top of the chamber is preferably arched, and from it project upwards strips of lead which are secured between iron plates, suspended by wires from the framework above; this allows of free expansion. The floor of the chamber is supported by reinforced concrete or sheet iron, perforated so that a leak may be readily located, and the angle between the floor and the wall is also encased in sheet iron which may be perforated, so as to hasten cooling and prevent the corrosion usual at this part. Glover and Gay-Lussac towers may be constructed on the same principle, which is said to allow more uniform expansion and contraction and minimise corrosion of the lead.—F. SOEX.

Copper nitrate; Manufacture of —, chiefly for use in agriculture and viticulture. H. Gouthière et Cie and P. Ducaucel. Fr. Pat. 395,806, Jan. 7, 1908.

A SOLUTION of copper nitrate for use in agriculture and viticulture is made by mixing solutions of commercial calcium nitrate and copper sulphate. The product is claimed to be most active if prepared just before use, and the calcium sulphate also formed is said to be of service to the soil.—F. SOEX.

Potassium chloride and other salts; Vessel for the refining of —. Maschinenfabr. Bikan, Akt.-Ges. zu Magdeburg. Ger. Pat. 207,887, March 26, 1907.

IN the refining of potassium chloride and other salts by washing them with water or suitable solutions, a double vessel is used, the inner chamber of which is perforated. After the covering or washing liquor has run through into the outer chamber, the inner one is lifted bodily out, carried over a suitable receptacle, and emptied. According to the present patent, the inner chamber is mounted on pivots or hinges on one side, and its contents emptied out by raising the other side.—A. S.

Alkali thiosulphates; Process for the preparation of —. Destrée et Cie. Ger. Pat. 208,633, May '06, 1908.

THIOSULPHATES are prepared by treating a solution of a bisulphide or a hydrosulphide with a bisulphite, the latter being added gradually and the mixture warmed to 60° C. The preparation of sodium thiosulphate in this way may be represented by the equations:

—A. S.

Calcium carbide; Process and apparatus for making — J. S. Seymour, Whitney Point, N.Y. U.S. Pat. 916,495, March 30, 1909.

THE finely powdered raw materials are intimately mixed with air and fuel and injected into a combustion chamber in the form of a blast, which impinges upon a bed of the mixture to be acted on. The region of highest temperature where chemical reaction takes place, is kept clear of excess of material, and the incoming mixture is preheated by the issuing hot gases and finished product.—O. R.

Silicon; Production of — G. O. Seward, East Orange, N.J., and F. von Kugelgen, Holcombs Rock, Va. Assignors to Virginia Laboratory Co., New York. U.S. Pat. 916,793, March 30, 1909.

A porous mixture of silica and carbon or some carbonaceous reducing agent is subjected in an electric furnace to a temperature above that at which silicon carbide remains stable. By keeping the are deeply immersed in the mass, a cooler and non-oxidising atmosphere is maintained around the reducing zone, and in this atmosphere the volatilised element is condensed.—C. A. W.

Peroxide of hydrogen; Method of making durable solutions of — J. Arndts, Paderborn, Germany. Eng. Pat. 6919, March 28, 1908.

SEE Ger. Pat. 196,370 of 1907; this J., 1908, 448.—T. F. B.

Peroxide of hydrogen; Process for electrolytically producing — G. Teichner, Nuremberg, Germany. U.S. Pat. 916,900, March 30, 1909.

SEE Fr. Pat. 388,527 of 1908; this J. 1908, 898.—T. F. B.

VIII.—GLASS, POTTERY, AND ENAMELS.

Felspar, flint, and china clay; Action of heat on binary mixtures of — A. Heath and J. W. Mellor. Trans. Eng. Ceram. Soc., 1907—1908, 7, 80—100.

Two bodies may begin to react and actually flux together at temperatures below the melting point of either. Thus, felspar, melting at 1150°C ., begins to react with quartz and china clay below 1000°C . The less fusible constituents of a body are attacked by the more fusible materials to form a viscous solution. If the process were allowed to complete itself, the ware would lose its shape. Pottery chemistry is therefore a chemistry of arrested reactions, and deductions from phenomena associated with completed reactions are often misleading. The progress of the reaction, however, can be followed empirically by measuring the contraction, porosity, or specific gravity at different stages of the firing. The porosity figure obtained by the ordinary soaking method is only the apparent porosity, owing to the presence of air bubbles completely surrounded by glassy flux impermeable to liquid. The authors describe how to obtain the porosity *in vacuo*, and explain how to calculate the true porosity. A piece of felspar fired in china biscuit gave the following figures:—0.3 per cent. porosity by ordinary soaking, 6.12 per cent. porosity by soaking *in vacuo*, and 15.15 per cent. true porosity. But it is doubtful if the results obtained justify the trouble of deducing "true porosity." Contraction is primarily an effect of the surface tension of the more fusible constituents of the mixture. If bubbles of gas are developed in the body, the body will "bloat," thus masking the real contraction. A body containing a high proportion of flint, may expand on firing, owing to the changes in volume which flint undergoes when heated. Three sets of experiments were made with the felspar and china clay mixtures. One set was fired in the earthenware glost oven, another in the earthenware biscuit, and the third in the china biscuit oven. Tables are given of the contraction and porosity, but the errors of experiment are great. Roughly speaking,

increased contraction attends the addition of china clay to felspar, and the authors compare this with the effect of quartz on the softening of felspar, and of bone on the softening of china. The apparent porosity curves run fairly consistently with the contraction curves and with one another. Microscopic examination showed development of sillimanite crystals in the china biscuit oven in the mixtures: felspar 45 to kaolin 55, and felspar 75 to kaolin 92.5 per cent. Under ordinary conditions of firing, felspar can dissolve approximately 20 per cent. of china clay to form a clear solution, and 15 per cent. of flint.—H. H. S.

"Spit-out"; The adsorption and dissolution of gases by silicates. B. Moore and J. W. Mellor. Trans. Eng. Ceram. Soc. 1907—1908, 7, 1—20.

"SPITTING," a bubbled appearance of the surface of the glaze, is often attributed to the glaze itself, but the authors opine that at least 80 per cent. of cases of "spitting" are due to moisture or organic matter in the body. Organic matter may find its way into the body in several ways—imperfect oxidation in the biscuit oven of carbonaceous matters in the bone and clays; reducing gases in the glost or biscuit oven; tarry matters condensing on the cooler parts of the ware in the enamel kiln and finding their way into the body; the "resist" on ware in "acid decoration" working into the body; and the decomposition of hydrocarbon gases by red-hot porous earthenware causing carbon to deposit in the pores. Associated with this is the brown patching of green china, which is often accompanied by "spitting." The "greening" is caused by ferrous phosphate, which, if oxidised, would become brown, and any organic matter present would be simultaneously oxidised (see this J., 1906, 265). Earthenware is remarkably tenacious of moisture, which the biscuit may imbibe through the unglazed parts. Old ware is particularly liable to "spit" for this reason. Moisture may also appear to act as a reducing agent by cutting off the supply of oxygen, the steam preventing the combustion of hydrocarbons until the kiln is at a fairly high temperature, when sudden oxidation takes place with consequent "spitting." When "spitting" is a glaze effect, the phenomenon is more complex. It may be due, as in the body, to absorption of carbon or hydrocarbons; hot glazes absorb oxygen, and the combustion of the hydrocarbons may take place below the surface of the glaze. The bubbles may be caused by the chemical reactions in the glaze, if the temperature be not high enough to give a glaze sufficiently mobile to clear itself of bubbles. The presence of sulphates leads to "spitting." Seger found that the greater the acidity of the glaze, the less is its carrying capacity for sulphates, a bisilicate glaze saturated with sulphates containing 4 per cent. of sulphur trioxide in solution, whereas a trisilicate contained only 2 per cent. Hence if the glaze dissolves silica from the body, sulphur trioxide, sulphur dioxide, and oxygen would be ejected from the glaze. Also, when lead volatilises from a glaze saturated with sulphates, the glaze becomes more acidic and sulphur oxides are given off. To this cause, the authors attribute tendency of fritted lead glazes to blister more readily than raw lead glazes; the fritted bisilicate would become more acidic during the reaction and consequently less able to hold sulphates. Sulphates may also cause "spitting" by reduction to sulphites. Finally, a glaze may "spit" on cooling, having taken up an abnormal amount of gas, and the phenomena of devitrification, which may be overcome by alumina, is similarly accompanied by "spitting."—H. H. S.

Glazes; Solubilities of metallic oxides in — III., IV., and V. C. E. Ramsden. Trans. Eng. Ceram. Soc., 1907—1908, 7, 21—36.

IN a previous paper (this J., 1906, 266) the author dealt with the solubilities of nickel and manganese oxides in glazes maturing at about 1050°C . III. *Chromium oxide*.—The solubility is seldom greater than 1 per cent. It varies with the composition of the glaze and can be increased by adding silica to a lead glaze; reducing the boric anhydride whilst maintaining the acidity with silica; adding about 0.5 per cent. of tin oxide to the glaze; lowering the alumina as much as is

consistent with the prevention of devitrification; replacing the zinc oxide by lead oxide (which is contrary to the results obtained with oxides of nickel, manganese, and copper, but similar to iron oxide); or by replacing part of the lead oxide by alkalis. In the absence of R_2O bases, the proportion of lead oxide must not be lower than 0.7 molecular part in an unfritted glaze. If the lead oxide exceeds 0.7, it can be partly replaced by lime or baryta. The solubility seems to be greater at $1050^\circ C.$; at $1100^\circ C.$ the glazes are not so clear. The quicker the cooling the more likely is the glaze to be free from coloured separations. When clear the lead glazes are yellow-green. The colours are made browner by alumina, clay, tin oxide, baryta, and lime, the last named producing an orange shade. The finest greens are obtained in a slightly reducing atmosphere. A bright green, quite distinct from that of lead glazes, results with alkaline glazes, and this is made yellower by alumina. Volatilisation from a transparent chromium glaze is small, but if the glaze be saturated with the oxide, there is condensation on the fireclay box covering the tiles. *IV. Iron oxide.*—The solubility varies from 3 to 14 per cent. It can be increased by adding silica; lowering the alumina (though this will impoverish the colours); replacing lime by lead in a lead glaze (contrary to the results with oxides of nickel, manganese, and chromium, but agreeing with those obtained with copper oxide); or adding baryta or magnesia. In a lead glaze, the silica may be replaced by boric acid up to $0.5 B_2O_3$, and in an alkaline glaze up to $1.5 B_2O_3$. In the absence of R_2O bases the lead must not be lower than 0.7 PbO in an unfritted glaze. The solubility varies directly with the temperature, but the colours are impoverished at 1100° . The quicker the cooling after complete fusion, the clearer the glazes. The colour imparted by iron oxide is the well-known brown. In a lead glaze it is improved by alumina, clay, and boric acid, and greatly augmented by barium. Far more oxide is required to give the same tint in leadless glazes; it is strengthened by silica, alumina, and boric acid. No volatilisation of iron has been observed. *V. Copper oxide.*—The solubility is 3 to 8 per cent. It can be increased by adding silica, replacing silica by boric anhydride; or lowering the alumina or kaolin. In the absence of R_2O , the lead oxide should not be less than 0.7 molecular part. If it exceed this, a small portion may be replaced by zinc oxide or magnesia. Lime and baryta have little influence. The colours are generally spoilt at $1100^\circ C.$, and the turquoise tint of the alkaline glaze is destroyed above $1000^\circ C.$ Separations from the glazes are less, the quicker the cooling. The colour of the lead glazes is green, made browner by adding kaolin or copper oxide and by a higher temperature. The alkaline glazes are blue-green, and turquoise is obtained at a low temperature in the absence of alumina and by raising the silica. Volatilisation of copper is considerable when the glaze is saturated with oxide, and is greater in lead than in alkaline glazes. Decomposition of the surface takes place in a few months in lead glazes unless the proportion of boron exceeds $0.5 B_2O_3$, and to a less extent in alkaline glazes, when again the iridescence diminishes with increase of boric anhydride.

In the subsequent discussion, Solon referred to a magnificent brown which the Japanese obtain by introducing nickel oxide into the body and volatilising this oxide at 1200° — $1400^\circ C.$ —H. H. S.

Copper red; Development of — in a reducing atmosphere.
L. Franchet. Trans. Eng. Ceram. Soc., 1907—1908, 7, 71—79.

"ROUGE-FLAMBE" seems to have been developed originally by the Chinese, its first occurrence being probably accidental. It was introduced to Europe by Ebelmen and Salvétat, who analysed the glaze from a Chinese vase and obtained the following figures:—silica 73.9 per cent., alumina 6.0, iron oxide 2.1, lime 7.3, soda 3.1, potash 3.0, copper oxide 4.6. In 1879, at Sèvres, Lauth examined the effect with a view to manufacturing it on the large scale, but his resources did not enable him to build a special oven for the purpose. Consequently, the cooling was much slower than in the small experimental oven; it was impossible to keep the atmosphere in the necessary reducing condition; and "greening" took place. By

adopting a down-draught oven of two cubic metres capacity with three fire-mouths, and putting the regulating damper at the base of the chimney, the present author is able to manufacture the copper red industrially with a loss of less than four per cent. The body used is a mixture of kaolin and pegmatite vitrefying at cone 10. The glaze must contain alkalis, lead, and a quantity of tin oxide greater than that of copper oxide, the best results being obtained with 10 per cent. of lead oxide, 3 of copper oxide, and 8 of tin oxide. A better red is produced by fritting the copper glaze before use; the fritting need not take place in a reducing atmosphere. The glaze, with a little gum tragacanth added, is best pencilled on (2 mm. thick), as the irregularities produced by the brush give more varied effects than in dipping or spraying. The ware should be fired in closed saggars (unglazed); in open saggars, the reducing gases come much more easily into contact with the vases, but so does the subsequent oxidising atmosphere. The reducing fire lasts 9 hours; at cone 0.12 the oxidising fire is started and goes up to cone 10, lasting 12 hours. The cooling must be done as quickly as possible; the pieces are drawn 48 hours after the fires are extinguished.—H. H. S.

Reverberatory furnace for burning porcelain, porcelain enamel, faience and pottery, with oil, wood or gas firing.
J. B. Nicolas, A. Yvernaud, and J. B. Coindeau. Fr. Pat. 395,302, Aug. 31, 1908.

A NUMBER of fire-grates are placed around a central chamber containing the goods to be burnt. The flames from the grates pass up to the crown of this chamber through flues, then down through the chamber itself, emerging into a canal placed below the chamber. The hot gases then ascend a second series of flues and pass through a second chamber placed above the first into the chimney.—A. G. L.

Glass articles; Fire glazing or finishing of —. M. Cummins, Manchester. U.S. Pat. 916,959, March 30, 1909.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Building stone; Kessler's "fluates" for protecting — against frost. A. Hanisch. Mitt. Tech. Gewerbe Museums in Wien, 1909, 19, 44—46.

THE author subjected various limestones and sandstones that are used for building in Vienna to freezing and thawing 25 times. It was found that the untreated stones crumbled rapidly, but those that had undergone the Kessler "fluating" process possessed a most satisfactory resistance. This process is described as treating the stone with silicofluorides, with the result that resistant double-silicates are formed.—H. H. S.

Trass-lime mortar; Influence of the method of mixing on the strength of —. H. Burchartz. Mitt. kg. Materialprüfungsamt, Gross-Lichterfelde West, 1909, 27, 38—45.

THE author shows that the best results are obtained with trass-lime mortars (with or without the addition of sand)

if the trass is most intimately mixed with the lime. The official method of the German union for the testing of materials of construction does not secure sufficiently intimate mixing.—A. G. L.

PATENTS.

Plastic material and process of making the same. W. E. Carson, Riverton, Va. U.S. Pat. 915,060, March 9, 1909.

THE plastic materials consist of mixtures of lime (3 or 6 parts) with hydrated alumina, e.g., bauxite (1 part) and only sufficient water (6 or 4 parts) to slake the lime and to leave a dry powder after the excess of water has evaporated. The water may be added to a mixture of lime and bauxite, or, preferably, lime may be slaked with water containing bauxite in suspension. The hydrated alumina may be replaced by hydrated ferric or chromic oxide. The resulting materials set and harden on further addition of water. In practice they are mixed with 85 or 88 parts of dry slaked lime, and 3 parts of sand or filling material is added to 1 of the mixture.—A. G. L.

Aluminous materials [for abrasives]; Treatment of —. A. C. Higgins, Worcester, Mass. U.S. Pat. 916,866, March 30, 1909.

ALUMINA or other aluminous material is fused, and the fused product is chilled in the furnace into a pig or mass of practically uniform character, and subsequently crushed.—O. R.

Preserving wood and the like. B. Diamand, Idaweiche, Germany. U.S. Pat. 917,265, April 6, 1909.

A VESSEL is filled with the wood and an impregnating liquid. A part of the liquid is then withdrawn, while the entry of air is prevented so as to produce a vacuum within the vessel. The liquid is then again introduced into the vessel, while any gases given off by the wood are allowed to escape. The liquid is then again partially withdrawn while entry of air is prevented, after which the liquid is again forced in under pressure, and the whole contents of the vessel maintained under pressure for some time.—A. G. L.

Preserving wood; Process for — by permanently fixing large quantities of metallic salts in the wood. J. Gerlache. Fr. Pat. 396,235, Nov. 14, 1908.

THE wood is impregnated with an aqueous solution containing free ammonia and ammonia compounds of copper and zinc (e.g., ammoniacal solutions of copper sulphate and zinc chloride).—A. G. L.

[Silica] bricks; Treating —. G. Dallavedova. Fr. Pat. 395,463, Oct. 19, 1908.

IMMEDIATELY after burning, the bricks are immersed for 3–4 days in sea-water or other saline or acid liquid. After air-drying, the bricks are heated to 100° C., and when thoroughly dry are immersed for several minutes in hot tar or in a hot mixture of oil and tar.—A. G. L.

Waste gases from ring-kilns; Process for utilising — especially for the preliminary heating of bricks. H. Köddewig. Fr. Pat. 396,233, Nov. 14, 1908.

AN annular or ring kiln is provided with a long external tunnel, through which the raw bricks travel on endless bands or rails in one direction, whilst the air which has been used for cooling the burnt bricks, together with hot products of combustion from the burning chambers, traverse the tunnel in the opposite direction.—A. G. L.

Rotary kiln for cement. Soc. Anonyme des Ciments Français. Fr. Pat. 395,978, Nov. 5, 1908.

THE burning zone of a rotary kiln is surrounded by a fixed envelope, which communicates at the top, by means of valved pipes, with the open air and with a second narrow envelope, which completely surrounds the kiln at a point in its upper part where the drying of the cement material takes place. This second envelope communicates with the interior of the kiln by a tuyère revolving with the kiln.

By this arrangement the hot air from the outside of the burning zone is utilised to assist the drying of the materials. Hot gases from the chamber at the base of the chimney may also be used for the same purpose, by providing a valved pipe leading from this chamber to the hot-air conduit described above. If this second device is used, the chimney must be partially closed by a damper.—A. G. L.

X.—METALS AND METALLURGY.

Pyrites; The increasing consumption of —, and its supply. B. Wetzig. Z. angew. Chem., 1909, 22, 721–724.

THE export of pyrites from Spain in 1870 was 200,000 tons, whilst in 1907 the export from the port of Huelva alone was 2,600,000 tons. In addition, 400,000 tons were shipped from Portuguese ports, and over 100,000 tons from Seville, the total export from the Huelva district thus exceeding 3 million tons. The consumption of pyrites for the Leblanc process has remained stationary during the last 30 years, and the increased export is required chiefly for use in the manufacture of superphosphate and ammonium sulphate. In 1907 the production of superphosphate reached nearly 5 million tons, an increase of 300,000 tons on the preceding year. No exact estimate can be formed of the quantity of pyrites still available, but Vogt has given the following figures for the Huelva district:—Rio-tinto mine, 130 million tons; Tharsis mine, 30 million tons; and other parts of the district, 10 million tons. The author considers the estimate for the Rio-tinto mine to be too low, but the quantity of pyrites containing over 15 per cent. of copper is probably less than 130 million tons. It is doubtful whether the whole of the Tharsis pyrites is of saleable quality, but the estimate for the other parts of the district is too low. At the present price, the annual export from Huelva is not likely to increase. With reference to the future demand for pyrites, other possible sources of sulphur are considered. The sulphur ore of Sicily is unsuitable for export unless the sulphur content is first increased to 30 or 40 per cent., and the use of this ore otherwise than locally is improbable. The residues left after the extraction of copper from low-grade copper-pyrites, as formerly practised in the Huelva district, do not form, as is often supposed to be the case, an additional source of sulphur, owing to the wasteful methods which were adopted. Attempts to convert native calcium phosphate into a soluble phosphate without the use of sulphuric acid have all been unsuccessful. By melting the insoluble phosphate with silica, a product similar to Thomas slag is obtained, costing about the same as superphosphate but less efficient as a manure. Nitric acid obtained from atmospheric nitrogen is not at present cheap enough for the manufacture of superphosphate. The decomposition of the native phosphate by heating with sulphurous acid under pressure is incomplete, and the recovery of sulphur dioxide by heating the calcium sulphite is impracticable owing to the formation of calcium sulphate and sulphide. The demand for pyrites is thus likely to continue to increase unchecked, and an increase in price may be confidently expected.—A. T. L.

Pig-iron in the electric furnace; Production of — from pyrites residue. F. E. Carcano. *Electrochem. and Met. Ind.*, 1907, 7, 155—156.

WHILE admitting that at the present time the electric furnace cannot in general compete with the blast-furnace for the production of pig-iron, the author draws attention to a case where it has been able to do so. About 100,000 tons of pyrites ash containing 46—57 per cent. of iron with about 2 per cent. of sulphur are yearly abandoned in Italy, because it would be difficult to treat such a powdered material rich in sulphur in the blast-furnace, especially in the absence of suitable iron ore and cheap coke. Water power is however available close to these refuse heaps, and in Lombardy, where the experiments were carried out, the kilowatt-hour costs only 0.09d., whereas small coke and coal dust cost respectively about 10s. and 16s. 8d. per ton, while furnace coke such as is used for the blast-furnace would cost £2 1s. 8d. per ton. Two types of electric furnace were used. In the first, two groups of electrodes were in series, with a carbon hearth and magnesia lining, and the gas and flame were allowed to escape. The second was an arc furnace with a vaulted roof for the recovery of the gases. The latter is the more economical for a permanent plant. The cost of making pig-iron in the first furnace works out at £2 9s. 10d. per ton, and in the second two or three shillings less. In the same locality if a blast-furnace were used, the cost of making pig-iron would be £3 0s. 5d. per ton. Not only therefore was the cost less, but there was no preparation of raw material. The following materials have been obtained:—

	Sulphur.	Phosphorus.	Manganese.	Silicon.
Foundry iron, . . .	0.046	0.063	2.23	3.53
Open hearth iron . . .	0.031	0.070	1.44	5.68
Spiegel	0.015	0.069	11.25	3.30
Silico-spiegel	0.020	0.065	12.66	8.90

In comparing the electric furnace with the blast-furnace, it should be remembered that:—(1). It is possible to use impure ores directly in the electric furnace which cannot be so used in the blast-furnace. (2). Coals of various kinds may be used. (3). It is easy to make castings direct, or to convert rapidly the pig-iron into a special steel in a second electric refinery furnace. (4). Silicon, manganese, or other elements can be easily incorporated with the steel.—A. H. C.

Steels; Study of the gases evolved by the action of cupric salts upon —. E. Goutal. *Compt. rend.*, 1909, 148, 988—991.

WITH a view to completing his previous work in connection with the potassium-cupric-chloride method for the determination of the total carbon in steels, etc. (this J., 1899, 521), the author has investigated the gaseous products evolved during the process of dissolution by which the carbonaceous residue is obtained for combustion. By treating one portion of the steel with the slightly acidified double chloride in a current of pure nitrogen, with suitable washing and absorption arrangements, the carbon dioxide and carbon monoxide in the gaseous products were quantitatively determined; whilst, by a modification of the process, the total carbon in the gases derived from the treatment of another portion of the steel was estimated, results thus being obtained for residual carbon, carbon evolved as dioxide, carbon evolved as monoxide, and carbon evolved as other unidentified gases. It was found that the total carbon in the gaseous products derived from different kinds of steel varied between 0.01 per cent. and 0.05 per cent. (calculated on the steel), about half of which was due to carbon dioxide occluded by the carbonaceous residue, from which it was expelled on desiccation. The author concludes that the loss of carbon experienced in the potassium-cupric-chloride process, as usually conducted, may be entirely obviated by heating the reagent to boiling during the dissolution of the steel, mixing the gaseous products with excess of pure oxygen, passing the mixture slowly over a heated platinum spiral and absorbing

the resulting carbon dioxide; and by omitting to dry the carbonaceous residue before the final combustion.

—W. E. F. P.

Special steels; Analysis of —. J. Pepin-Lehalleur. *Monit. Scient.*, 1909, 23, 263—264.

THE author discusses the methods proposed by Blair (this J., 1908, 902), and describes those which he has found most satisfactory in practice. For the separation of molybdenum from other metals by means of ether, it is best to take a special portion of the metal. The solution of the metal in hydrochloric acid of sp. gr. at least 1.12, should have a volume of 60 c.c. and be shaken twice with 40 c.c. of ether. Under these conditions only about 2 mgrms. of molybdenum remain in the acid solution. The ethereal solution should not be washed with hydrochloric acid. The ether is distilled off from the solution, the residue evaporated with sulphuric acid until white fumes appear, then re-dissolved in water, and the molybdenum precipitated by passing hydrogen sulphide through the hot solution. The precipitated sulphide is heated to bright redness in a current of hydrogen sulphide. Vanadium may be determined accurately by Campagne's method (this J., 1903, 1149). The author first precipitates it as manganese vanadate in ammoniacal solution, and then dissolves the precipitate in concentrated hydrochloric acid. In absence of tungsten, chromium may be determined by converting it into chromate, reducing this with Mohr's salt (ferrous-ammonium sulphate), and then titrating the excess of ferrous salt with permanganate. For determining tungsten, silicon, and chromium when present together, the metal is dissolved in hydrochloric acid, a small quantity of nitric acid added, the solution evaporated to dryness, the residue dissolved by means of hydrochloric acid and potassium chlorate, and the solution evaporated. The residue is now dissolved in boiling dilute hydrochloric acid, and after standing for 1 hour, the solution is decanted through an ashless filter, and the residue washed by decantation twice with dilute hydrochloric acid and once with dilute nitric acid. The solution (A) is set aside. The residue is treated with 50 c.c. of boiling dilute ammonia solution which dissolves the tungstic acid and a small proportion of the silica, and the solution is filtered through the paper used previously, the latter being then washed with ammoniacal water. The filter-paper and insoluble matter are incinerated, weighed, treated with hydrofluoric acid in the usual manner, and again weighed, the difference representing the chief proportion of the silica. The ammoniacal solution is concentrated, treated with 5 c.c. of nitric acid, evaporated to dryness, the residue heated to dull redness for 5 minutes, weighed, treated with hydrofluoric acid, and again weighed. The difference corresponds to the remainder of the silica, and the weight of the final residue represents the tungstic acid. The residue left from the determination of the chief quantity of the silica is fused with bisulphate, the product dissolved in water, added to solution (A), and the chromium determined in the usual manner. Tests for the qualitative detection of molybdenum, and of vanadium in presence of chromium are also given.—A. S.

Ferro-nickel; Cast — spoiled by working at too high a temperature. E. Heyn and O. Bauer. *Mitt. kg. Materialprüfungsamt Gross-Lichterfelde West*, 1909, 27, 1—7.

Two pieces of ferro-nickel, which showed fissures on working, were examined. Their composition was: Nickel, 5.5 per cent.; carbon, 0.09; manganese, 0.59; silicon, 0.22; phosphorus, 0.01; sulphur, 0.03; and copper, 0.12 per cent. Microscopic examination showed a coarse structure, similar to that of cast ingots; on reheating for one hour at 900° C. the structure became fine-grained. On working reheated samples it was found that fissures were produced if the temperature to which the samples were heated was too high. But the maximum temperature permissible depends not only on the time of reheating, but also on the size of the pieces heated. Thus, pieces with a cross-section of 10 by 10 mm. could be heated safely for periods up to

2 hours at 1200—1300° C.; but pieces with a cross-section of 40 by 55 mm. could not be heated much above 1100° C. without showing fissures on subsequent working.

—A. G. L.

Welding and hard-soldering. C. Diegel. Chem.-Zeit., 1909, 33, 427—428.

THE plates to be welded (in making stills, boilers, dryers, etc.) formerly consisted entirely of wrought-iron, but at present mild steel is almost exclusively used. Siemens-Martin steel with a tensile strength of 30—40 kilos. per sq. mm. being the most suitable. The iron should contain less than 0.01 per cent. of phosphorus, if possible, and certainly not more than 0.04. Too much sulphur, copper, or silicon, or too little manganese render the iron hot-short. The manganese should not be less than 0.4 per cent. for 0.01 per cent. of silicon; but iron with 0.75 per cent. of manganese and 0.15 per cent. of silicon can be readily welded. Mild steel becomes brittle at about 300° C. or on cooling after being heated to above 1000° C.; in the last case, heating for a short time to 900° C. restores the original tenacity. The different methods of welding iron are as follows:—1. Electrically, by passing a large ampère and low voltage current between the superimposed pieces. 2. By means of the arc; either by an arc formed between one of the pieces of iron and a carbon rod; or, by an arc formed between two carbon rods and deflected magnetically; or else, by forming an arc between one of the pieces to be joined, and an iron rod, which melts and flows into the space between the two pieces. 3. The thermite process. 4. Autogenous welding by melting the two edges together in a gas flame (hydrogen, acetylene or coal-gas and oxygen). 5. Welding by hammering or rolling, the pieces being heated in a coke-fire or by water-gas, both gas and air being supplied to the burner under pressure in such quantities as to give a reducing flame. Thin sheets, up to 6—8 mm. in thickness, are preferably joined by a hard solder. Brass is generally used, but copper and bronze are also employed. Increasing content of zinc renders the solder more fusible, but diminishes its tenacity; by adding 4—10 per cent. of silver the solder becomes easily fusible and strong. As flux, borax, or "Perlinax" is used.—A. G. L.

Electrochemistry of the solution of gold in potassium cyanide. J. B. Ekeley and A. L. Tatum. Western Chemist and Metallurgist, 1909, 5, 19—23.

MCLAURIN in 1893 (this J., 1893, 359) showed that the presence of oxygen is necessary for the solution of gold in potassium cyanide. Following the lines of Christy's researches (this J., 1901, 259; 1902, 779), the authors constructed a cell composed of electrodes of gold on the one hand and oxygen (platinised platinum in oxygen) or the other in an electrolyte of potassium cyanide. With cyanide solutions of concentrations varying from 0.05 to 0.45 per cent., in all cases much larger quantities of gold were dissolved with the external circuit closed than when this was open, and the results indicate that were it possible to supply oxygen at a sufficiently rapid rate to the platinised platinum and exclude all oxygen from the cyanide solution, then the solubility would be directly proportional to the current according to Faraday's law. Measurements of the potential of gold in cyanide solutions against the oxygen electrode gave results agreeing with the measurements of Christy and others against the normal calomel electrode. Considered electrochemically the solution of gold in potassium cyanide may be represented by the equation: $4Au + 8K' + 8CN' + 2H' + 2OH' + 2O' = 8K + 4Au(CN)_2' + 4OH'$, the gold dissolving on account of the formation of innumerable short-circuited gold-oxygen cells. The four charges carried by the oxygen ions may, however, be supplied in other ways. If furnished by mechanical means, gaseous hydrogen would be evolved as solution of the gold proceeded: $2Au + 4K' + 4CN' + 2H' + 2OH' = 4K + 2Au(CN)_2' + 2OH' + H_2$. The solution of gold in a cyanide solution containing cyanogen bromide is represented by the equation: $2Au + 3K' + 3CN' + Br' + CN' = 2K + 2Au(CN)_2' + K' + Br'$.

—A. S.

Cyanide lixiviation [of gold and silver ores] by agitation.

W. M. Brodie. Eng. and Min. J., 1909, 87, 695—696.

IN the Brown or Pachuca tank, which consists of a tall tank having a conical bottom, with a central air lift (see this J., 1908, 1065), the compressed air which is introduced at the bottom of the tank, causes an active circulation of the pulp by inducing an upward current of the solution containing the slimes, through the central air lift. The circulation is however impeded if fine concentrates or sands collect in the conical bottom, round the air-lift pipe. In order to overcome this, a series of pipes is arranged either round the central air-lift pipe or attached to the inner walls of the tank, extending from just below the working surface of the solution to within 6—18 in. of the lower end of the air-lift. When material has settled in the cone and the air supply is turned on, solution passes down these pipes and washes away everything in the apex of the cone, thus allowing the accumulation to sink and in turn be washed away. The circulating pipes, which are generally three or four in number, have their upper ends fitted with return elbows, so that ore fed into the tanks, or coarse settlements thrown up by the lift, may not fall down the pipes. The great advantage of the circulating pipes is that a much larger proportion of sands can be stirred effectively than in any other of the customary agitation vats, so that complete sliming of the ore is unnecessary.—F. R.

Silver cyaniding; Recovery of metals from solutions in —.

M. R. Lamb. Eng. and Min. J., 1909, 87, 705.

IN order to reduce the large quantity of zinc required to precipitate the precious metals from rich cyanide solutions, the author proposes that about 85 per cent. of the values be removed by electrolytic deposition and the remainder be precipitated in zinc boxes, thus removing the difficulty of electrolytically treating solutions containing very small amounts of silver or gold.—F. R.

Borax in assay fluxes. J. E. Clennell. Eng. and Min. J., 1909, 87, 696.

IN order to ascertain whether the use of borax as an assay flux gave rise to any loss of precious metal, comparative tests were made on a quartzose ore containing iron oxide, using fluxes free from, or containing varying amounts of borax. It was found that the presence of 5—10 grms. of borax in the flux, per assay ton of ore, was advantageous as it increased the fusibility of the charge, but when larger proportions of borax were used, the slag became hard and stony and the lead button was only separated from it with difficulty. There was no evidence that borax carried any appreciable amount of gold into the slag, but when too large a proportion of borax was used, a film of lead almost invariably broke off the button and adhered tenaciously to the slag, giving rise to mechanical loss.—F. R.

Determining vanadic and arsenic acids and vanadic and antimonie acids in presence of each other. Edgar. See XXIII.

Copper production of the world. H. R. Merton and Co., March, 1909. [T.R.]

THE world's production of copper in 1908 amounted to 748,625 tons, compared with 713,865 tons in the previous year, 429,626 tons 10 years ago, and 279,391 tons in 1891. For three years the production by the principal countries has been as follows:—

	1906.	1907.	1908.
	tons.	tons.	tons.
Australasia	36,250	41,250	39,500
Canada	25,466	25,615	29,570
Chile	25,745	26,685	38,513
Germany	20,340	20,490	20,200
Japan	42,540	48,535	43,000
Mexico-Bolco	10,830	10,975	12,400
Mexico, miscellaneous	49,795	45,590	25,170
Peru	8,505	10,575	15,000
Russia	10,490	15,000	20,085
Spain and Portugal	49,320	49,675	52,585
United States	409,650	392,520	425,175
Total	714,100	713,865	748,625

Platinum; Its occurrence and extraction. W. Geibel.
Z. f. Elektrochem., 1909, 15, 212—218.

THIS is a prize essay, containing besides descriptions of the direct methods of extraction of the metal itself, also those of the separation of the various associated metals from the crude platinum. The entire subject is classified as follows:—I. Occurrence and extraction. II. Geographical and geological data, etc. III. Description of the individual deposits. IV. Methods of extraction. V. Statistics as to prices and production. VI. Winning the ore, and separating the platinum metals. VII. Working process. VIII. Uses. It is shown that whilst the deposits worked in 1879 yielded 5 oz. of metal per ton, the present average is much below 1 dwt. There is some platinum in all the streams running east or west from the Urals, and there is much probability that those running northwards may contain it in quantity. More elaborate and scientific methods of operating are employed in the larger workings than those used in the small and scattered workings. This fact explains how that in these larger workings economy of labour can be afforded, and thus deposits of lower grade can be turned over to profit. It is still estimated that at least 10 per cent. of the total platinum found is stolen.

PATENTS.

Sulphide ores or products; Treatment of —. W. Hommel, London, and The Metals Extraction Corporation, Ltd., London. Eng. Pat. 6511, March 24, 1908.

THE ore is roasted in order to remove the bulk of the sulphur; it is not advantageous however to eliminate the whole of that element but only such portion as will pass away in an oxidising calcination. The product is then mixed with a certain amount of carbon or carbonaceous matter, together with residues produced in the later part of the process, and subjected in a blowing furnace to an air-blast. The whole of the zinc, together with some small amounts of lead and silver, is volatilised and condenses in the flues in the form of oxide. The residue contains nearly the whole of the lead, silver, gold and copper, and may be treated in any suitable manner or the recovery of these metals. The zinc oxide product, after suitable agglomeration, is mixed with some form of carbon and distilled for the metal in the usual manner, the residue in this case being again employed in the preliminary distillation, as above.—C. A. W.

Oxides and sulphides; Reduction of metallic — for the purpose of obtaining the corresponding metal. E. Chatillon. Fr. Pat. 395,658, Jan. 3, 1908.

THE process is particularly applicable to the case of antimony, existing either as oxide or sulphide. The mineral sulphide having been melted in a furnace of appropriate design, it is run into a receptacle and subjected to the action of a current of air which may either be blown in or passed over the surface. When the oxidation, which is never complete but results in a mixture of oxide with oxysulphide and unreduced sulphide, has come to a stop, the current of air is cut off, and reduction effected by blowing in industrial gases rich in hydrogen, hydrocarbons, and carbonic oxide, such as coal gas, water-gas, or gases obtained from the distillation of wood. The metallic vapours produced in the reduction are led into a double condensing chamber, of which the interior compartment has walls composed of filtering tissues, the filtered gases passing away through a chimney. The process may be carried out in a furnace with inclined hearth with a cavity in the lower portion to serve as a receptacle for the molten ore. Moreover, in order to prevent volatilisation, it is convenient to cover the mass with some inert fusible material, such as common salt.

—C. A. W.

Muffle furnace; Hardening —. A. Mergler, Cologne, Germany. Eng. Pat. 17,367, Aug. 18, 1908.

A GRATE is provided close to one side of the muffle. The hot gases from this grate first pass over a partition placed close to this side of the muffle, then down beneath the partition and the muffle, next horizontally beneath the muffle, then up past the other side of the muffle, and finally over the top of the muffle to the flue, which is

placed close to the partition. The muffle is supported on a number of transverse ridges, which form passages through which the hot gases pass.—A. G. L.

Furnace; Ore-reducing —. G. F. Rendall, New York, Assignor to American Reduction Co., New Jersey. U.S. Pat. 916,487, March 30, 1909.

THE furnace, used in calcining ores, comprises a revolving chamber which is connected by means of a conduit with an externally heated retort, the latter being used for the production of combustible gas. Means are provided for mixing this gas with air as it passes into the calcining chamber, and also for preventing any further combustion in the receiver where the residual portions are collected.

—C. A. W.

Alloy; [Bearing metal —]. W. G. Black, St. Louis, Mo. U.S. Pat. 912,645, Feb. 16, 1909.

THE alloy, which consists of copper 50—60, iron 40—50, nickel 4—6, lead 6—15, and aluminium 0.25—0.5 per cent., is made by adding the nickel to the previously melted iron and when these have alloyed, adding the copper and aluminium and after well stirring, finally adding the lead. The mixture is again well stirred before pouring. The percentage of lead determines the relative softness of the alloy, and the nickel is said to act as a lubricant when the alloy is used as a bearing metal.

—F. R.

[Gold and silver] Assaying; Process of —. J. C. Hames, Goldfield, Nev. U.S. Pat. 913,129, Feb. 23, 1909.

THE finely divided ore, say half an assay ton, is mixed, preferably dry, with three times its weight of a mixture, substantially consisting of 1 part of gum camphor, 20.736 parts of iodine, and 41.471 parts of potassium iodide, then adding water equal to 14 times the weight of the ore and stirring the whole. The gold is precipitated from the solution by the addition of 0.75 dram of sodium amalgam and is afterwards recovered by the usual methods. In assaying for silver, the same method is employed, except that instead of the amalgam, an amount of sodium cyanide equal in weight to the ore, is added, the silver being afterwards precipitated from the solution with zinc shavings or dust. The zinc precipitate is dissolved in nitric acid and the silver determined in the solution.

—F. R.

Gold; Extraction of — from cyanide solutions with simultaneous regeneration of the alkali cyanide. P. de Wilde. Fr. Pat. 396,170, Nov. 11, 1908. Under Int. Conv., Nov. 20, Nov. 28, and Dec. 16, 1907.

THE cyanide solution containing dissolved gold is slightly acidified by addition of hydrochloric acid or sodium bisulphate. In order to collect the liberated aurous cyanide, which is present in so small a quantity that the liquid appears absolutely clear, a small amount of cuprous chloride, dissolved in a concentrated solution of common salt or in hydrochloric acid, is added and the mixture agitated for a few minutes. The precipitate of cuprous cyanide, which settles rapidly after a short rest, is found to have carried down with it the whole of the aurous cyanide. The liquid having been decanted off, the precipitate may be treated with moderately concentrated hydrochloric acid, when the cuprous cyanide will be dissolved without decomposition, the gold compound being left untouched. The solution of cuprous cyanide may then be employed again. The acidified solutions of cyanide deprived of their gold are subsequently treated with a slight excess of caustic alkali, when the resulting mixture is ready for the treatment of a fresh quantity of ore. Certain varieties of carbon, such as those obtained by calcining nitrogenous animal products with potassium carbonate likewise possess the property of absorbing and fixing large quantities of aurous cyanide.

—C. A. W.

Ores and the like; Calcining, desulphurising, agglomerating, and sintering —. F. D. Weeks, Salida, Assignor to Ohio and Colorado Smelting and Refining Co., Colo. U.S. Pat. 916,903, Mar. 30, 1909.

THE apparatus consists of a stationary annular grate on to which the material is fed by means of a hopper

which moves in a rotary path along the surface. The material having been ignited by means of a burner affixed to the hopper, the combustion is maintained by a current of air which is drawn down through the mass, the strength of the draught being regulated by an exhauster arranged to that end. Finally the roasted product is swept from the grate-surface by means of a scraper attached to the hopper and movable therewith.—C. A. W.

Cast iron; Method and product for soldering — with metals or alloys. G. Fano fu Gustavo and G. Voghera. Fr. Pat. 395,283, Oct. 15, 1908.

The solder consists essentially of a metallic salt easily decomposable by heat, a deoxidising agent, melting at the temperature of fusion of the metal by which the actual joint is made, and a small quantity of an energetic oxidising agent, this last being used when the iron has a high content of carbon (5 to 6 per cent.). The soldering metal should fuse at a temperature below the melting point of the most fusible of the metals it is required to solder. In the composition specified, zinc chloride, 38 parts; sodium borate, 60 parts; potassium permanganate, 2 parts, the action depends upon the breaking down of the first into chlorine, which cleans the surface of the iron, and zinc, by which the actual weld is made. —C. A. W.

Iron and steel articles; Coating of — with a view to preserving them from rust. Langbein-Pfanhauser-Werke A.-G. Fr. Pat. 395,409, Oct. 16, 1908. Under Int. Conv., Dec. 21, 1907.

THE objects of iron or steel, having previously received a coating of lead, are covered with zinc electrolytically. In this way there is produced at the surface of contact of the two metals an alloy of lead and zinc which, since it shows the potential of zinc, offers the same protection against rust as would a coating of that metal alone. A smaller deposit of zinc may be employed if, subsequently, the object be brought to a temperature such that the formation of the alloy is extended through the entire coating.—C. A. W.

Alloy of magnesium and iron or of iron and a magnesium alloy; Production of an — suitable for the deoxidation of cast iron and steel. Chem. Fabr. Griesheim-Elektron. Fr. Pat. 396,009, Nov. 6, 1908.

THE direct addition of magnesium to molten iron or steel is not possible without the risk of an explosion. It is however found that the addition may be made at the moment when the bath is passing from the solid to the liquid condition, that is when it constitutes a thick pasty mass. As such a procedure would not be possible in practice, it is preferable to prepare previously a ferro-magnesium alloy in the above manner and to add this to the bath as in the ordinary addition of ferro-manganese. If it be desired to add nickel, aluminium, or other metals to the molten bath, these may be alloyed with the magnesium which is then used in the preparation of the ferro-alloy as before.—C. A. W.

Aluminium alloys; Method of obtaining —. J. A. Boutes. Fr. Pat. 395,331, Oct. 6, 1908.

UNDER ordinary conditions it is not possible to obtain aluminium containing more than 5 to 6 per cent. of heavy metals without impairing its mechanical properties. The fact that a solution saturated with any substance is able to take up a certain proportion of another substance which may be soluble in the original solvent is applied to the production of ternary and quaternary aluminium alloys. To this end, the several metals, in the liquid condition, are added one by one to the molten solvent. The process may be modified by melting first of all the metal with the highest melting point and proceeding in the reverse order, finally adding the requisite amount of aluminium. In this way alloys such as aluminium-

silver-copper and aluminium-copper-nickel-zinc may be obtained, excelling in malleability and ductility those of the binary type.—C. A. W.

Tantalum; Manufacture of metallic —. Siemens und Halske A.-G. Fr. Pat. 395,730, Oct. 28, 1908. Under Int. Conv., Nov. 16, 1907.

TANTALIC acid or other oxygen compound of tantalum is reduced by carbon at a white heat. It is found that a pure metal can be obtained in this way if all access of air be excluded during the operation. To this end the reduction may be operated in a current of hydrogen and, in order to avoid as far as possible the formation of carbonic acid, such a proportion of carbon is taken as will lead to the production of carbon monoxide alone. In one method of heating, the mixture of oxide and carbon is pressed into sticks, a little tantalum powder being added if necessary to give the requisite conductivity, and the whole brought to the particular temperature by the passage of the electric current. Although the metal may absorb large quantities of hydrogen, this can subsequently be removed by fusion in the electric furnace under reduced pressure.—C. A. W.

Ores; Process for preventing the concretion of — in mechanical roasting furnaces. E. W. Kauffmann. Fr. Pat. 395,848, Oct. 31, 1908.

IN the roasting of sulphide ores, the great rise in temperature produced by the oxidation of the sulphur may lead to the fusion of the smaller particles, which consequently tend to become agglomerated. In a mechanical roasting furnace of the upright type having, for example, five floors, this effect would be most noticeable on the second and third floors where the oxidation is at an early stage and the content of sulphur is high. It is therefore proposed to increase the velocity with which the ore travels over these floors and in this way reduce the disengagement of heat in the same proportion. To this end the teeth fitted to the radial arms in the zones in which concretion may occur are arranged at a greater inclination to the line of flow, and thus present a greater working surface, than on the other floors.—C. A. W.

Tin-plate; Removal of tin from — by means of chlorine. H. von Schütz. Fr. Pat. 395,999, Nov. 6, 1908. Under Int. Conv., Nov. 15, 1907.

THE tin-plate, packed on the floor of the chlorination chamber, is freed from moisture by submitting it to a current of hot air. The chamber having been exhausted, the cooled material is subjected to the action of the gases obtained by allowing liquid chlorine and liquid air to spontaneously evaporate into the vacuum. In this way a further cooling is obtained, so that the temperature, which tends to rise as a consequence of the heat of reaction, never becomes too high. Moreover the pressure produced never becomes much greater than atmospheric pressure, and the gases, which pass into the chamber through several tuyères, act uniformly on the material. The liquid stannic chloride as it drops from the metal is collected in a gutter and run off from time to time, and in order to remove the last traces, a current of water is passed in, after which the plates are again dried by the action of heated gases. After removal to a second chamber where they are gently heated and become covered with a film of oxide, the plates are rolled out and cut up into pieces of the required shape. The washing with water may be omitted, when the last traces of chloride will be removed in the final heating in the second chamber.—C. A. W.

Zinc from zinciferous lead and other low-grade zinc alloys; Process for the recovery of —. D. Coda. Ger. Pat. 207,019, June 21, 1907.

AN alloy of copper or of copper and aluminium with lead is added to the fused alloy containing zinc, in order to concentrate the zinc in a dross which is practically free from silver and can be distilled. Good results are obtained with an alloy containing about 94 per cent. of lead and 5 of copper, obtained by reduction of a mixed ore con-

aining radium. The alloy can be easily melted with inciferous lead, and is said to have the power of withdrawing from the latter about 10 per cent. of its weight of zinc, forming a dross, which yields metallic zinc on distillation. The patentee ascribes the action of the alloy to a physical modification of the copper caused by the presence of small quantities of radium.—A. S.

Electric smelting in British Columbia. Times Eng. Suppl., May 5, 1909, 19. [T.R.]

DURING 1908 the Canada Zinc Company erected at Nelson, British Columbia, an electric smelter for the treatment of mixed ores of lead and zinc by the method of F. T. Snyder. (This J., 1907, 879.) This plant has been installed for smelting 15 tons of ore per day with provision for an increase to 40 tons. It is situated on the water front of Kootenai Lake and represents an investment of £22,000.

The ore as received by rail or water, first enters a sampling department where it is crushed to the size of wheat, and sampled for analysis. From the sampling department, it is bedded down after mixing with the requisite fluxes, etc., in storage bins holding 100 tons each. From the bedding bins the ore is fed automatically by a feeder to a roaster of the McDougald type specially modified for roasting the mixed lead zinc ores. This roaster consists of a number of circular hearths superposed upon each other to reduce radiation, down which the ore is stirred by arms projecting from a central vertical revolving shaft. From the roaster the red-hot finished ore, which by this time has lost most of its sulphur, falls into a revolving cooler which delivers it cold and dry to the storage bins for the electric furnace. The electric furnace, similar in appearance to an ordinary lead or copper water-jacketed furnace with electrodes for carrying electricity, in place of tuyères for taking in a blast, receives the roasted ore at the top and melts it down into slag. The lead produced, sinks through this slag and passes into a crucible at the bottom of the furnace. The zinc is vaporised and led to condensers, where it condenses into a sump and is ladled out into pigs.

The ore of the Slocan district is exceptionally high in silver (shipments in excess of 100 oz. to the ton being common) and this silver is not a direct constituent of the galena but of an associated grey copper ore (freibergite), assaying, when picked out, 4000 to 5000 oz. of silver to the ton.

With heat generated in the charge of ore and not having to penetrate from the outside (through retort or furnace walls, &c.), the retort can be enlarged to a point where machinery can replace hand labour with corresponding decreased labour costs per ton. No heat having to pass through the walls, these can be made thick and mechanically strong. With internal electrical heat it is not necessary to keep the retort horizontal; it can be placed vertically and the ore either fed in from the top or forced in from the side. Certain other advantages follow from the vertical position. Any lead in the charge, instead of falling against and corroding a hot wall, will fall to the bottom and can be collected separately from spelter. But the principal advantage from the electrical firing is that the residues can be so strongly heated as to melt them, whereby not only is it possible to completely expel the zinc as vapour, but the residues can be removed by the low-labour plan of tapping off slag. But the principal advantage of the electric furnace is that the zinc in the charge is no longer oxidised, and may be condensed

and saved. The slag, being freed from the burden of dissolving this zinc, requires less iron and can be compounded to carry away lower lead and silver values. From 800 to 1200 horse-power hours are required per ton of material fed into the furnace, varying with the zinc content of the charge. This amount of electricity can be generated from steam with the coal required (2250 lb.) per ton of ore by the retort method of zinc smelting. The use of electricity, however, involves the cost of electrodes. In practice this has been found to vary from £5 to £20 per ton of furnace charge, varying with the composition of the charge and the physical character of the electrodes.

PATENTS.

Electrolytic parting of gold bullion and gold alloys; Process for the —. Norddeutsche Affinerie, A.-G. Ger. Pat. 207,555, Sept. 22, 1908.

The electrolytic parting is effected in solutions containing excess of hydrochloric acid or chlorides with either an asymmetric alternating current or with both a direct and an alternating current working either in parallel or in series. The process is carried out with current-densities of 500–1000 ampères per sq. m., and the solution of gold chloride forming the electrolyte may be cold, in which case it should contain at least 3 per cent. of free hydrochloric acid; or warm, when the amount of free acid must be less than 1 per cent.—A. S.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

Mutton tallow; Mixed glycerides of palmitic and stearic acids in —. A. Bömer, Z. Untersuch. Nahr. Genussm., 1909, 17, 353–396.

IN a former communication (this J., 1907, 974) the author showed that the most insoluble glyceride in beef and mutton fats was tristearin, of which the former fat contained about 1.5 per cent. and the latter about 3 per cent. In the present paper it is shown that a very large number of fractional crystallisations is required to separate the glycerides of the saturated fatty acids in mutton fat. The mixed glycerides thus separated were dipalmitostearin (4 to 5 per cent.) and palmitodistearin (4 to 5 per cent.). The presence of tripalmitin is doubtful, and in any case this compound cannot form any considerable proportion of the saturated glycerides. The dipalmitostearin after repeated recrystallisation melted at 57.3° C. (57.5° C. corr.), or about 2.3° C. higher than the similar glyceride isolated by Hansen from mutton fat. It had a saponification value of 201.4 (theory, 201.8) and the amount of stearic acid, determined by Hehner and Mitchell's method, in its separated fatty acids agreed with the theoretical amount. The palmitodistearin melted at 63.0° C. (63.3° C. corr.), whilst the glyceride separated by Hansen (this J., 1902, 553) melted at 62.5° C., and that isolated by Kreis and Hafner (this J., 1904, 755) at 63.0° C. Both of these mixed glycerides showed the same m.p.s. whether crystallised from a solution or solidified after melting.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, &c.

(A.)—PIGMENTS, PAINTS.

Thioindigo and indigo; Use of — as pigments for oil-paints. E. Täuber. Chem.-Zeit., 1909, 33, 417–418.

THE author describes further experiments with different preparations of indigo and thioindigo, all of which have confirmed his former conclusions (this J., 1908, 1073) that both pigments when used in oil-paints fade in the course of a few weeks. He is unable to confirm the statement of Eibner (this J., 1909, 373) that there is a fundamental difference in this respect between indigo and thioindigo. Pure synthetic indigo, however, proved not only to have more colouring power, but also to be considerably more stable than natural indigo or artificial indigo precipitated with alumina. Moderate heat accelerates the bleaching process. Thus layers of oil-paints containing these pigments, which at the ordinary temperature took several weeks to fade, were bleached in one or two hours when exposed in the dark to a temperature of 40° to 60° C. Conversion of indigo or thioindigo into alkali salts of their sulphonic acids obviates their instability as pigments in the presence of oil. This is attributed to these sulphonated salts being insoluble in oil, and it is suggested that it may be possible to prepare serviceable oil-paints from thioindigo red and allied compounds by converting their sulphonic acids into metallic salts completely insoluble not only in oil but also in water.—C. A. M.

PATENTS.

Amorphous carbon; Apparatus for the preparation of — by decomposition of hydrocarbons. J. Machtoff, K. Bosch, F. Closs, and G. and T. Boehm. Ger. Pat. 207,520, Nov. 9, 1907.

IN the preparation of amorphous carbon by the decomposition of hydrocarbons by means of an electric spark (see Fr. Pat. 364,034; this J., 1906, 894), claim is made for the use of a series of connected decomposition chambers, only the first of which is provided with a sparking device. The chambers are connected by tubes provided with non-return valves. On passing the spark, the pressure produced in the first chamber by the explosion, and the flame, pass on to the second chamber, causing explosion of the hydrocarbon therein; and so on throughout the series.—A. S.

Soot; Process for increasing the yield of — from coal-tar, coal-tar pitch, and similar substances. Rütgerswerke, A.-G. Ger. Pat. 208,600, May 24, 1908.

THE raw materials (coal-tar, coal-tar pitch, etc.) are first extracted with a suitable solvent, the solution is separated from the residual "free carbon," and is then either as a whole, or after expelling the solvent, burnt in the usual manner for the production of soot. The "free carbon" has the same composition and may be used for the same purposes as soot. As suitable solvents, naphthalene and heavy coal-tar oils are specified, and special claim is made for the use of the former.—A. S.

(B.)—RESINS, VARNISHES.

Turpentine; Determination of petroleum in —. J. H. Coste. Analyst, 1909, 34, 148–151.

AS the result of further work, the author still maintains that Armstrong's method, if properly applied, is the most trustworthy one for the determination of petroleum spirit in turpentine (see this J., 1908, 694). Petroleum oil

should be determined by distillation of the original sample in a current of steam, and petroleum spirit by polymerisation of either the distillate from this process, or another portion of the original. In discussion, L. M. Nash stated that petroleum spirit could be detected in turpentine, and its quantity determined fairly accurately, by shaking the sample in a graduated tube and comparing the resulting froth with that produced by similarly shaking mixtures of known composition. The amount of frothing is in direct proportion to the quantity of petroleum spirit present, turpentine itself giving no froth.—W. P. S.

Colophony; A colour reaction of —. J. Sans. Ann. Chim. Analyt., 1909, 14, 140—141.

Ox gently heating a minute quantity of colophony with 1 or 2 c.c. of methyl sulphate, a rose coloration changing to violet and then to deep violet is obtained. On increasing the temperature the colour disappears, leaving only a faint brown tint. This reaction is very characteristic and is given by resins, soaps, etc., containing traces of colophony. It is more simple than Halphen's test (this J., 1909, 151), and the coloration is more distinctive than those obtained in Liebermann's reaction. Neutral ethyl sulphate gives a similar coloration. In the author's opinion the colorations are due to traces of free sulphuric acid, invariably present in methyl and ethyl sulphates, and the test may be employed conversely, to determine the degree of purity of those compounds.—C. A. M.

Shellac; Analysis of —. H. Endemann. Z. angew. Chem., 1909, 22, 676—677.

In analysing shellac by the author's method (this J., 1907, 1207) it is essential to have the residue left after the evaporation with hydrochloric acid thoroughly dry. If it does not yield a clear solution in alcohol after the addition of one drop of acid, the drying has been insufficient, and the evaporation must be repeated with fresh portions of hydrochloric acid. The test for rosin by means of sulphuric acid and sugar should be applied to the alcoholic extract, not to the original shellac, the colouring matter in which has a disturbing influence on the results. Further examination of samples of genuine shellac have confirmed the author's conclusion that the proportion soluble in alcohol is only about 8 per cent. Granular lacs (*Körnerlacke*), however, form an exception, and may yield as much as 16 per cent., due to matter extracted from fragments of twigs and insects present as impurities. When these lacs are used in the preparation of shellac, the impurities remain in the filter-bag, and are sold as "refuse shellac." This contains as much as 70 per cent. of shellac and fat, and in the powdered form can only be recognised by microscopical or chemical examination. The trihydroxypalmitic acid previously found in hydrolysed shellac is oxidised by alkaline permanganate to sebacic acid and δ -hydroxycaproic acid. When heated to about 130°—140° C., it loses a mol. of water and is converted into an amorphous elastic anhydride, insoluble in alcohol. By long continued boiling with sodium hydroxide this anhydride can be again hydrated. The acid separated from the new product, however, now crystallises in needles, which also lose a mol. of water when heated. Shellac which had been adulterated with a considerable quantity of rosin gave these needles directly.—C. A. M.

(C.)—INDIA-RUBBER, &c.

Latex of Ficus elastica; Presence of a rennet in —. V. Cayla. Caout. et Gutta-percha, 1909, 6, 2852.

A SMALL quantity of latex was obtained from incisions in a *F. elastica* grown under glass. Of this, five drops were added to five c.c. of sterile cow's milk, contained in a test-tube. The latex was very faintly acid, but not sufficiently so to neutralise the natural alkalinity of the milk. After 10 minutes' incubation at 45° C., no change could be detected, but in 15 minutes the milk was completely coagulated. The existence of vegetable rennets is already known, one such occurring, for example, in the latex of the fig tree, another *Ficus*. The presence of such an enzyme in rubber latex may have an important bearing upon methods of coagulation, and the author raises the question as to whether its presence in the latex examined is the result of the growth of the plant under abnormal conditions, or whether the rennet also occurs in the latex of trees grown under normal conditions.

—E. W. L.

Guayule rubber. I. and II. T. Whittelsey. J. Ind. and Eng. Chem., 1909, 1, 245—249. (See this J., 1903, 1250, 1358; 1905, 203; 1906, 704; 1908, 633, 1123.)

THE guayule shrub (*Parthenium argentatum*) contains about 9 per cent. of "pure rubber," calculated on the dry substance of the whole plant. The crude rubber contains about 20 per cent. of resin. It softens more quickly on the rolls than most other rubbers, but can be used in place of many of the African rubbers. The amounts of guayule rubber received at New York were 850,000 lb. in September, 929,500 lb. in October, and 1,444,000 lb. in November, 1908.

Distribution of rubber in different parts of the shrub.—Different parts of the plant were extracted with water and with alcohol, and then the rubber extracted with carbon tetrachloride. The following results were obtained:—

	Dry weight.	Rubber.	Weight of rubber.	Rubber, per cent. of total.
	grms.	per cent.	grms.	
Trunk bark	349	21.4	74.7	25.7
Root bark	127	19.5	24.8	8.5
Branches and leaves	1918	9.7	186.0	64.0
Trunk wood	404	0.0	0.0	0.0
Root wood	255	2.0	5.1	1.7
Totals	3053	—	290.6	99.9

Thus the dry substance of the whole plant contains 9.5 per cent. of rubber. The percentage of rubber in the air-dried plant is 7.8. The trunk wood contains no rubber, but yields to alcohol an elastic resin, which when dried in a steam oven, becomes insoluble in alcohol, acetone, and carbon tetrachloride. Unless special care be taken, some of this resin may be returned as rubber in the analysis of the plant. It is possible that the "rubber" extracted from the root-wood is also really a resin analogous to that

yielded by the trunk wood, but insoluble in alcohol. This question is being further studied. In view of the results given above, the relative amounts of wood and of bark were determined. The trunks of the shrub contain 46.4 per cent. of bark and 53.6 per cent. of wood, whilst two plants weighing 235 grms. and 152 grms. contained 54.6 and 57.8 per cent. of bark respectively. It would appear, therefore, that the use of an efficient decorticating device before extracting the rubber would result in considerable economy.—A. S.

Ebonite and vulcanite: Manufacture of — [from waste materials]. O. C. Immisch, Finchley, Eng. Pats. 28,159 and 28,365, Dec. 24, 1907.

(1). WASTE ebonite or vulcanite, reduced to powder, or in the form of shavings, is filled into a mould, where it is subjected to considerable pressure in order to consolidate it, the mould being cold during this process. The mould is then locked and heated to a certain critical temperature, dependent upon the amount of sulphur present in the waste, but which is in the neighbourhood of 400° F. At this temperature an abnormal expansion of the material takes place, resulting from the fact that sulphur, when heated to about 400° F., undergoes a physical change and assumes a semi-plastic condition. A high degree of compression is thus brought about in the mass, and a dense product obtained when the mould is allowed to cool and opened. (2). Waste ebonite or vulcanite is reduced to such a state of division (turnings or shavings), that the bulk of it per unit weight is considerably greater than that of the same material in a granulated or pulverised condition. It is then placed in a cold mould, of greater capacity than the volume of the article required, subjected to a high pressure, and the mould clamped and heated at about 280° F. for a time depending on the dimensions and weight of the mould. While the mould is cooling, it is subjected to further pressure, and when cool it is locked and heated to a temperature of over 400° F. Finally the mould is allowed to cool, before being opened. In the manufacture of articles of large dimensions, it is desirable to provide means, such as a spring, for taking up any excessive pressure produced by the change of physical condition in the ebonite at 400° F., in order to avoid damage to the mould.—F. W. L.

XIV.—TANNING, LEATHER, GLUE, SIZE.

Tanning materials; Notes on some western (U.S.A.) —. J. H. Russell and F. O. Sprague. J. Amer. Leather Chem. Assoc., 1909, 4, 92—95.

THE native tanning materials at present used by Californian tanners consist only of oak and Mexican bark, the former being far the most important and constituting the main source of tannin on the West Coast. Analysis of this oak bark shows it to contain about 5 per cent. more tannin than a good quality Eastern rock oak bark. Although the proportion of tannin to non-tannins is greater in the Californian than in the Eastern oak, the difference is not great enough to account for their very different action in the tannery. This difference is chiefly due to dissimilar bacterial conditions in eastern and western yards. The oak bark liquors in Californian yards do not develop acid as do oak bark liquors in Eastern tanneries. What a Californian tanner terms "souring his liquors," consists mainly of a viscous fermentation causing the liquors to become stringy and jelly-like, but not developing sufficient acid to de-lime or plump the goods. Leather tanned with the extract prepared from this bark is much redder than that tanned with the bark itself and resembles hemlock leather. The so-called "Mexican" bark is very similar in many ways to mimosa bark but it gives a light reddish colour to leather, different from the pink of mimosa. Tanners

claim that it makes the leather plump but light and porous, and that the fibre has very little tensile strength. "Koa" bark has been used for tanning in the Hawaiian Islands and is said to give a leather similar to that tanned with Californian oak-bark but of redder colour.—S. H.

Chestnut wood: Analysis of —. W. K. Alsop. J. Amer. Leather Chem. Assoc., 1909, 4, 95—99.

THIS article is the result of research made on the lines suggested by Kerr (J. Amer. Leather Chem. Assoc., 1909, 77) for the analysis of spent chestnut wood. By extraction of the wood with water in the Teas extractor and subsequent analysis of solutions of different concentrations, it is apparent that the amount of extractive matter obtained from chestnut wood, depends upon the time of extraction and the rate of boiling, or amount of water passing on to the wood. Some substances soluble in the water are yielded almost indefinitely. In this method of extraction, the amount of tannin as shown by the hide powder method, increases to some extent as the extraction is prolonged. The author states that the method proposed by Kerr does not yield a definite amount of tannin but is influenced by the conditions of extraction as with the usual one, the proportional increase not being very different by the two methods. Tables are given showing results obtained several years ago in the extraction of chestnut wood, by the use of the Reed extractor and also by the Procter extractor, and the increase in tannin by prolonged treatment is about the same in both methods. On account of the practical impossibility of duplicating in the laboratory the conditions that prevail in the tannery, the author considers it extremely difficult to devise a general method of analysis of new and spent wood, that will give the yield as to extractive matter or tannin, that should be realised at the works.—S. H.

Tanning and treating skins, etc.; Tumblers for —. C. S. Bedford, Leeds, and H. Brewer and J. T. Hardy, Nottingham. Eng. Pat. 21,582, Oct. 12, 1908.

THE tumbler is provided, on its internal periphery, with dash-boards parallel, with one exception, to the main axis of the tumbler. The dash-board which forms the exception is inclined downwards towards the trunnion end plate of the tumbler, and, being provided with a return board along its inner edge, forms a trough along which liquid can travel towards the trunnion-end. Here the trough is connected with a box-shaped trough or spout which passes along the end plate of the tumbler towards the centre, where it communicates with a flanged gland pipe passing through the hollow trunnion. Whilst the tanning or other process is in operation, this pipe is kept closed by a cock, which is opened when the process is at an end, the tanning or other liquor being thus removed from the interior of the tumbler.—E. W. L.

Tanning machine. F. H. Tocum, London, Ontario. U.S. Pat. 916,821, March 30, 1909.

THE machine described comprises a vat, in which, near the top, is mounted a shaft, provided with radial arms. Inclined to the arms are plates provided on their inner faces with guideways to take the ends of the bars which support the hides. These bars are allowed a limited motion towards and from the axis of the shaft. Suitable means are provided for rotating the shaft.—E. W. L.

Sulphite-cellulose lyes; Process for purifying — for the purpose of obtaining a preparation suitable for the tannery. A. Kumpfmiller. Ger. Pat. 207,776, Aug. 1, 1906.

THE lye is first freed from the main portion of the sulphurous acid and calcium sulphite it contains by heating or by treatment in a vacuum. It is then treated with ozone, whereby the remainder of the sulphurous acid and calcium sulphite are converted into sulphuric acid and calcium sulphate respectively, the greater portion of the latter separating out. On now adding precipitated barium carbonate, the dissolved sulphuric acid and sulphate are precipitated. The liquor thus purified is suitable for use as a tanning and filling material for hides.—A. S.

Lithographic stones [from hides]; Substitutes for —.
E. T. Day, London. Eng. Pat. 21,239, Oct. 8, 1908.

Raw hides are unhaired and dried as usual. The hides are then immersed in a saturated solution of barium chloride for one day, and allowed to dry naturally. When nearly dry, they are again immersed for six hours in barium chloride solution, and again dried. When nearly dry, the hides are immersed in a weak solution of sulphuric acid (1:3000) for 12–24 hours. The hides are next dried on frames, rubbed with sand-paper, washed with a 10 per cent. solution of gelatin, dried, immersed in formalin, again dried, and polished. The whole process is then preferably repeated. Instead of using barium chloride as above, the hides may be washed with "a saturated solution of barium carbonate," allowed to dry, immersed in a saturated solution of barium hydroxide, and then treated as before.—A. G. L.

Skins; Machine for applying liquid to —. W. B. Turner, Melrose, Assignor to Turner Tanning Machine Co., Peabody, Mass. U.S. Pat. 917,683, April 6, 1909.

SEE Fr. Pat. 375,747 of 1907; this J., 1907, 936.—T. F. B.

XV.—MANURES, &c.

[Soils]. *Bacteriological-chemical investigations.* O. Lemmermann, H. Fischer, H. Kappen, and E. Blanck. Landw. Jahrbh., 1909, 38, 319–364. Chem. Zentr., 1909, 1, 1187–1188.

THE results of subjecting a number of soils of different kinds to different treatments are given. It was found that the nature and course of the reactions taking place in the soil could be studied most accurately in the soils themselves under conditions approaching the natural ones as closely as possible. By the use of a sand culture method (glass sand moistened with a nutrient solution), it was not possible to detect differences in the decomposition of organic nitrogenous compounds with soils of widely different character, nor could the actions of various fertilisers be differentiated. It was observed, however, that the action of denitrifying bacteria was weaker in the case of peaty soils than in that of mineral soils; in both cases the action was considerably increased by addition of lime, but other fertilisers had no noticeable effect. In the case of soils in which, in the natural condition (earth culture), denitrification was very weak, this became much stronger when the soil was added to a sand culture, whilst when the soil was introduced into a nutrient solution (liquid culture), all nitrate was decomposed in a short time. The nitrate-nitrogen was for the most part converted into protein-nitrogen. With these soils, an action of stable manure could be observed only with earth cultures. By means of earth cultures it was found that ammonium sulphate when added to soils manured with Thomas meal and kainite, was utilised to a greater extent by peaty soils than by clayey soils. Of the ammonia-nitrogen utilised, most was converted into nitrate-nitrogen, especially in the peaty soils. The quantity of nitrogen and the relative proportions of the different forms of nitrogen compounds in sandy and clayey soils were not appreciably altered by sterilisation, but in humic soils the quantity of nitrogen capable of being liberated (as ammonia) by magnesia was increased. The nitrogen compounds of sterilised mineral soils were, however, more easily decomposed by bacteria than those of sterilised humic soils. With earth cultures nitrification proceeded more vigorously in clayey than in sandy soils. In soils which were sterilised and then treated with a suspension of the same soil unsterilised, the original nitrifying power was not regained during the time of the experiments. Drying the soils also weakened the nitrifying power, and no denitrification took place in dried soils. Sterilisation also weakened the power of the soil to decompose calcium cyanamide. In natural soils formation of ammonia and nitrification may proceed side by side. In general, the authors conclude that in order to obtain an accurate notion of the reactions in the soil, experiments must be made

with the fresh natural soil and analytical determinations must be made throughout the course of the experiments, not only at the beginning and end.—A. S.

Soil fatigue caused by organic compounds. O. Schreiner and M. X. Sullivan. J. Biol. Chem., 1909, 6, 39–50.

COWPEAS were grown repeatedly on a sandy loam soil until the yield, which was very good at first, became poor, although on the same soil, wheat and potatoes would grow well. The cause was found to be due to the presence in the "sick" soil of a substance toxic to cowpeas. By mixing the soil with a large quantity of water and distilling with steam, a turbid distillate was obtained, a portion of which, when filtered, proved much less satisfactory than distilled water as a medium for the growth of cowpeas. By standing and also by extraction with ether, a quantity of fine, needle-shaped crystals was separated from the distillate. A saturated aqueous solution of these crystals proved to have a very marked retarding action on the growth of cowpeas. The soil which had been subjected to steam distillation gave much better yields of cowpeas than the untreated soil.—A. S.

Phosphate rocks; Determination of iron oxide and alumina in —. T. S. Gladding. J. Ind. and Eng. Chem., 1909, 1, 249–250. (See this J., 1909, 102.)

FIVE grms. of the phosphate rock are boiled for 1 hour with 50 c.c. of hydrochloric acid (1:1), the solution is filtered, treated with a few c.c. of hydrogen peroxide solution, boiled to oxidise the iron and expel oxygen, cooled, and made up to 250 c.c. 25 c.c. of the solution (=0.5 gm. of sample) are heated to boiling, a slight excess of ammonia added, and then sufficient hydrochloric acid to just redissolve the precipitate. The clear solution is treated with 1 gm. of ammonium oxalate, boiled, and the calcium oxalate filtered off. The filtrate is evaporated with 5 c.c. of concentrated sulphuric acid until white fumes are evolved, in order to destroy the excess of oxalic acid, then cooled, treated with 50 c.c. of water and 5 c.c. of concentrated hydrochloric acid, and boiled until it becomes clear. It is then made up to 150 c.c., and the iron and aluminium precipitated as phosphates. The iron oxide is determined in 50 c.c. of the original solution of the phosphate rock by the bichromate or permanganate method.—A. S.

Cyanamide; Its manufacture in France, and its part in agriculture. Ch. Pluvinage. Bull. Soc. d'Encouragement, 1909, 111, 549–562.

Manure; Method of treating —. F. A. Goeckeler, Worcester, Mass., U.S.A. Eng. Pat. 5999, Mar. 18, 1908. Under Int. Conv., Mar. 18, 1907.

FRESH manure is treated with sulphuric and hydrochloric acids in sufficient quantity to fix the ammonia and salts, and to effect deodorisation, though not in sufficient quantity to decompose the manure. The resulting product may be exposed to the air for a long time without emitting foul odours or loss of valuable constituents. Suitable proportions claimed for this purpose are half a pint of a mixture of the acids in about equal proportions and 3 pailful of water to 128 cubic feet of manure. In cases where insufficient ammonia or ammonium compounds are in the manure, ammonium salts may be added to the mixture of acids.—C. A. M.

Phosphoric acid or substances [manures] containing phosphoric acid soluble in citric acid or water; Preparation of — from natural phosphates. N. A. Langlet. Fr. Pat. 396,195, Nov. 12, 1908. Under Int. Conv., Nov. 14, 1907.

THE invention relates to the preparation of phosphoric acid or a phosphate soluble in citric acid or water, for use as a manure, by treating the raw insoluble phosphate, such as apatite, with an ammonium salt, so as to liberate ammonia and produce phosphoric acid or a soluble phosphate, the ammonium salt being subsequently regenerated. Three cases are possible, according to the ammonium salt used:—(1). The calcium salt formed is soluble. When insoluble diacalcium phosphate is the other product,

the soluble calcium salt is separated from it by solution, and calcium carbonate is precipitated from the liquid by treatment with ammonia (obtained in the process) and carbon dioxide, thus regenerating the ammonium salt; when, by the use of more ammonium salt, phosphoric acid or monocalcium phosphate have been formed, the mixture is dissolved and di- or tricalcium phosphate first precipitated by ammonia, and then calcium carbonate is precipitated from the residual solution as before. (2) The calcium salt formed is sparingly soluble (e.g., the sulphate). Monocalcium phosphate or phosphoric acid is produced by using a sufficient quantity of the ammonium salt, and is then separated by solution from the insoluble calcium salt, which is treated with ammonia and carbon dioxide to recover the original ammonium salt. (3) When the ammonium salt is decomposed by heat (e.g., the sulphate or phosphate), it may be first heated (with or without steam) to drive off all or part of the ammonia, and the residual acid or acid salt may be used for treating the phosphate as above.—F. SOMER.

XVI.—SUGAR, STARCH, GUM, &c.

[Sugar] Cane; Relation between added water per cent. on —, and dilution per cent. of normal juice. H. Pellet. Internat. Sugar J., 1909, 11, 193—195.

THE author criticises the conclusion of Coombes (this J., 1909, 102) that the quantity of water added and calculated per cent. of cane cannot be higher than that expressing dilution of normal juice. As a preliminary it is remarked that the only way to calculate the water added to a given weight of cane is to measure the water entering at the mills, and, taking account of the temperature, obtain the water consumed in the mills for a given weight of crushed cane. This water only mixes incompletely with the juice present in the bagasse; consequently the juice extracted is more dilute than it would have been had the water been uniformly distributed over the bagasse, and the dilution of the extracted mixed juice is always greater than that calculated from quantity of water entering per cent. of cane. It also explains why there has been more difficulty in decreasing the richness of the bagasse when diluting 15 to 18 per cent. than when 24 to 35 per cent. of water is used.—L. J. DE W.

Sugars; Spontaneous oxidation of the —. A. P. Mathews. J. Biolog. Chem., 1909, 6, 3—20.

LEVULOSE, galactose, dextrose, maltose, and lactose oxidise rapidly in the presence of air if their solutions are alkaline, but not if they are neutral or acid. It would appear, therefore, that for oxidation it is necessary that a salt of the sugar be formed. This salt ionises and the sugar residue forming the anion is in a condition in which it readily decomposes, and is then easily oxidised. Of the sugars, levulose oxidises the most rapidly in alkaline solution; the others oxidise at about the same speed and about one-fourth as fast as levulose. With all the sugars examined, though less markedly in the case of levulose, there is an acceleration of the velocity of oxidation and decomposition as the reaction goes on. This is attributed to the fact that by the decomposition of each sugar molecule, several reducing molecules are produced, and hence the concentration of the reacting substances is increased. Oxidation is most rapid in $N/1$ sodium hydroxide in the case of levulose, and in about $N/2$ sodium hydroxide in the case of the other sugars. With stronger alkali, the rate of oxidation is reduced. The above results indicate that under the term of oxydases there have hitherto been confused two classes of substances: one which renders the oxygen active; the other—the more important class—which causes dissociation of the reducing substances, and thus renders them active.—A. S.

PATENTS.

Calcium sucate; Apparatus for making —. J. F. Pool, Philadelphia, Pa., Assignor to The American Sugar Refining Co., Jersey City, N.J. U.S. Pat. 912,887. Feb. 16, 1909.

This invention has for object the weighing and conveying of the lime and the feeding of the same into the cooling

apparatus, in a practically dust-proof case, and without handling. The apparatus includes a feed hopper, the neck of which is provided with a number of independent, co-acting valves, by means of which the quantity of powdered lime introduced into the weighing hopper below, can be controlled. The weighing hopper is mounted on the platform of a weighing scale, and is connected, above, to the feed hopper, and below, to a conveyor casing, by contractile and expansible tubes of closely woven cloth or other material impermeable to the powdered lime. The bottom of the weighing hopper is closed by a pair of overlapping and swinging valves, by means of which the weighed quantity of lime is discharged into the conveyor casing, to be carried from thence to a dust-proof hood at the top of the cooler of the calcium sucate apparatus, which may be of any desired character, e.g., that described in U.S. Pat. 861,893 (this J., 1907, 1023).—L. E.

Sugar masscutes with regular crystals; Process for obtaining crude — whereby economy is effected in the steam used for heating the vacuum apparatus. F. Tiemann. Fr. Pat. 395,753, Oct. 28, 1908. Under Int. Conv., Aug. 5, 1908.

THE masscuite pans are intercalated as elements in the multiple effect system, and are heated by steam at a temperature of 70° — 100° C. from this system (triple or quadruple effect). Owing to the low temperature of this steam, the slow concentration of the masscuite can be so regulated that the crystals already present increase in size and the formation of a further quantity of small crystal is avoided. A considerable economy of steam is also effected. To keep the masscuite in motion, a stirrer is used, or steam, from the same source as that used for heating, is injected directly into the masscuite.—L. E.

Bagasse; Process for drying wet material consisting of pieces, e.g., cane —. F. Tiemann. Fr. Pat. 395,863 Oct. 31, 1908. Under Int. Conv., March 4, 1908.

THE material passes downwards through a shaft and is subjected therein to the action of transverse currents of hot gases. Two opposite walls of the shaft, which diverge towards the base to allow for increase in bulk of the descending material, consist of louvre-boards inclined downwards towards the interior. One of these walls is divided longitudinally into sections to which funnels are adapted externally, so that gases from different sources or at different temperatures, may be introduced at different heights of the shaft; this contrivance also prevents loss of heat. After traversing the material, the gases pass out through the opposite louvre-wall.—L. E.

[Starch] syrup; Process of refining —. C. B. Duryea Cardinal, Canada. U.S. Pat. 916,683, March 30, 1909. SEE Fr. Pat. 380,680 of 1907; this J., 1908, 32.—T. F. F.

Maltose; Process of making —. C. B. Duryea, Cardinal, Canada. U.S. Pat. 916,685, March 30, 1909. SEE Eng. Pat. 11,799 of 1907; this J., 1908, 238.—T. F. F.

XVII.—BREWING, WINES, SPIRITS, &c.

Yeast; A yeast-poison in —. F. Hayduck. Spiritusind. 1909, 32, 127—128, 139—141, 150—151.

THE presence of a yeast-poison of a protein nature in certain cereals (this J., 1908, 85) led the author to see for a similar poison among the proteins of yeast itself. For convenience in manipulation, the present experiments were carried out on dried yeast, but similar searches with fresh yeast are in progress. It was found that when top-fermentation distillery yeast, rapidly dried at a high temperature (70° C.), was extracted with water acidulated with hydrochloric acid, an extract highly poisonous to bottom-fermentation beer yeast was obtained. On the other hand, the extract from yeast slowly dried in the air was non-poisonous. In neither case was it

extract, prepared with pure water, poisonous; in fact, pure aqueous extracts were rather stimulating. The difference in the behaviour of yeast slowly dried and that tried rapidly is attributed to the destruction of the poisonous protein by the activity of the tryptic enzyme in the former case. The poisonous extract is most readily obtained in a highly active condition by digesting 20 grms. of rapidly dried yeast with 2 litres of 0.1 per cent. hydrochloric acid for 2 hours at 50° C.; sulphuric and acetic acids do not extract the poison. The filtered extracts should be neutralised accurately with sodium hydroxide before testing. Whilst an extract of distillery yeast is poisonous to beer yeast, that of the beer yeast itself is stimulating; distillery yeast is stimulated by extracts both of beer yeast and distillery yeast. As in the case of the cereals, these peculiarities are due to the inhibitive action of calcium salts on the poisonous action of the protein; distillery yeasts are far poorer in calcium salts than bottom-fermentation beer yeasts, and therefore yield more poisonous extracts. If the calcium salts be eliminated as completely as possible, extracts may be prepared which are poisonous to both types, and which immediately lose their poisonous properties on the addition of a little chalk. The removal of calcium salts may be effected before extraction or by subsequent treatment of the extract. The treatment in the former case consists in making a preliminary extraction of the dried yeast with dilute hydrochloric acid or, still better, with pure water, before the extraction of the poison is started. Extracts made under these conditions show an increased toxicity towards beer yeast, but are still non-poisonous to distillery yeast; such a procedure readily yields an extract from beer yeast which is poisonous to beer yeast. A more highly poisonous extract is obtained by drying the yeast in a fresh state, than after keeping it for some time before drying; the latter condition is equivalent to slow drying. The most powerfully poisonous of all the extracts were prepared by eliminating the calcium salts from ordinary extracts by dialysis with chloroform water for 24–48 hours, and subsequent removal of the chloroform. In this way extracts prepared from beer yeast, which were either stimulating or only moderately poisonous before dialysis, were brought into such a condition that 95 per cent. of the cells of beer yeast were killed within 2 hours. By this method also it was possible to convert a distillery yeast extract, previously stimulating to distillery yeast, into one which was distinctly poisonous to distillery yeast. These observations form the foundation of a new explanation of many of the instances of degeneration or sickness of the yeast which occur in practice. They also illustrate the general theory of Delbrück with regard to the vital processes of cells, depending on the fine balance of activities summed up in the term "physiological condition."—J. F. B.

Starch in barley; Saccharification and polarimetric determination of —. F. Schubert. Oest.-Ungar. Zeits. Zuckerind. und Landw., 1909, 17; Z. Spiritusind., 1909, 32, 157.

For many reasons the polarimetric determination of the dextrose produced by the saccharification of starch is preferable to the cupric reduction method, but the processes hitherto described do not yield concordant results because the products are not of constant composition. The author has modified Geschwendner's and Parow and Lemmann's methods (this J., 1906, 870; 1908, 84) and claims that the results are concordant and satisfactory, and that none of the dextrose undergoes secondary decomposition. He uses as the saccharifying agent, an acid brine containing 100 grms. of salt and 0 grms. of hydrogen chloride per litre. Twenty grms. of barley grist are treated with 100 c.c. of this reagent in a 200 c.c. graduated flask, and the mixture is heated for 5 hours in a vigorously boiling water-bath provided with a constant level arrangement and a means for preventing superheating. An oil-bath provided with a thermo-regulator at a temperature of 98°–100° C. offers certain advantages. After cooling, the contents of the flask are diluted to the mark, filtered without clarification, and polarised. Since the true polarisation value of the

dextrose solution is not immediately established after dilution, the reading should be checked after standing for some little time. 1° Ventzke corresponds to 0.2941 grm. of starch and 1 circular degree to 0.8514 grm. of starch, with the 200 mm. tube. It is noted that it is not necessary to heat the liquid for 5 hours continuously; the saccharification may be interrupted and completed the next day if desired.—J. F. B.

Beetroots; Report on Collettes' process for extracting juice from — in the distillery. Lindet. Bull. Soc. d'Encour., 1909, 111, 468–472.

The employment of beetroots as raw material for the manufacture of alcohol, increases yearly. The advantages possessed by the process patented by A. G. and R. Collette (see this J., 1907, 1023), are the small cost of installation, the automatic working, the reduction of manual labour, and the thorough extraction attained. The amount of juice extracted (130 to 150 litres per 100 kilos. of beetroot), and the degree of extraction (0.2 per cent. of sugar being left in the exhausted cossettes), are such as are obtained under the best conditions of the diffusion process. The process is not suitable for sugar manufacture, since, owing to exposure to the air, the juice would be darkened by the oxydases of the beetroot, and the treatment with sulphuric acid which prevents this in the distillery process, should not be permitted in the sugar-house. The process, first installed in the Seclin distillery in 1907, was, in 1908, being worked in 13 factories.—L. E.

Helianthus tubers as a material for the production of spirit. J. Kocks. Z. Spiritusind., 1909, 32, 161.

ANALYSIS of various samples of *Helianthus* tubers shows that they contain 27.38–27.98 per cent. of dry substance, which consists of 11.69–14.06 per cent. of protein, 8.11–13.60 per cent. of sugar (laevulose), 58.33–60.52 per cent. of inulin (and other substances yielding sugar on hydrolysis with acids), and small proportions of fat, ash, and cellulose. The author has measured the yields of alcohol obtained by fermenting with beer yeast the tubers themselves or the expressed juice, either with or without preliminary treatment with dilute sulphuric acid, and distilling the fermented wash. The following numbers represent the yields of alcohol in litres obtained in four cases, from 100 kilos. of the tubers:—

	I.	II.	III.	IV.
Juice fermented, without sulphuric acid	5.16	5.16	5.33	4.07
Juice fermented, with sulphuric acid	8.21	8.10	9.40	6.60
Tubers fermented, without sulphuric acid	5.92	7.90	6.38	—
Tubers fermented, with sulphuric acid	8.83	7.90	7.97	—

—T. H. P.

Colour of turbid worts; Determination of the —. H. Roeder. Z. ges. Brauw., 1909, 32, 169–171.

When the colour of turbid worts is measured by means of iodine solution, better results are obtained by rendering the water, to which the iodine solution is added, turbid by the addition of an alcoholic colophony solution, yeast cells, isinglass, or hordein. When, however, comparison is made with prepared colour standards, this method cannot be employed, and it becomes necessary to clarify the wort. Such clarification cannot be effected by repeated filtration or centrifuging, but the author finds that if 100–120 c.c. of the turbid wort be vigorously shaken several times with 2–3 grms. of precipitated barium sulphate and filtered, until the liquid passing through the filter is bright, this liquid will have the same sp. gr. as, and will retain all the colour of, the original wort. Worts clarified in this way do not become turbid again even after standing for 24 hours.—T. H. P.

Cider; Composition of —. B. T. P. Barker and E. Russell. Analyst, 1909, 34, 125–134.

THE results of analyses of seven samples of cider, each made from a selected variety of apple, are given, and

also of six other samples which were blends collected from various sources and representing the type of cider which finds its way on to the market. The total solids contained in the samples varied from 2.1 to nearly 8 per cent.; the acidity, expressed as malic acid, from 0.22 to 0.59; the tannin, from 0.01 to 0.37; and the alcohol, from 2.7 to 6.69 per cent., by weight. The ash of the first seven samples lay between 0.246 and 0.441 per cent., whilst in the case of the blended ciders it varied between 0.308 and 0.346. The alkalinity of the ash (all the samples) varied from 0.02 to 0.156 per cent., and the phosphoric acid from 0.013 to 0.025 per cent. A comparison of these results with the standards suggested by various authorities (a synopsis of these standards is given in the paper) shows that whilst they may be of use in limiting the amount of adulteration of cider, they still leave a considerable scope for sophistication of pure-juice ciders of average quality. A test is described by means of which the presence of even small quantities of apple juice may be detected in ciders. The liquid under examination is concentrated by evaporation to one-tenth of its bulk and is then shaken with an equal volume of ethyl acetate; when separation has taken place, the ethyl acetate solution is drawn off and poured over the surface of a little lime-water contained in a test-tube. A yellow coloured zone appears at the junction of the two liquids if as little as 0.1 per cent. of apple juice be present. In a genuine cider this reaction is obtained without concentration. In an entirely artificial cider (even if tannin has been added) the characteristic reaction does not occur. In the discussion, F. J. Lloyd drew attention to the fact mentioned by Allen that boric acid is present in all genuine cider (see this J., 1902, 922), and suggested that this might be employed for distinguishing between genuine and artificial ciders. The presence of tannin in apple-juices also afforded a means of detecting artificial cider, which did not as a rule contain tannin.—W. P. S.

PATENTS.

Fermentation vessels; Quicksilver [mercury] closure for —. W. Lazarus, Kiel, Germany. U.S. Pat. 912,581, Feb. 16, 1909.

This invention depends on the discovery, that the resistance opposed by a funnel to the flow of a gas, is greater when the gas passes through the funnel from the base to the point, than when it passes in the opposite direction, whereas, with liquids, the reverse is the case. The apparatus consists of a U-tube, *a*, containing mercury, and provided, in its ascending limb, *a'*, with one or more funnels, *b*, the points, *c*, of which are directed downwards. To prevent the retention of mercury on the walls of the tube, a small quantity of water is placed on the mercury column in the ascending limb. To prevent this water from being carried away with the escaping gas, one or more bell-shaped, or other contrivances, *n*, are placed in the ascending limb, a very narrow space between the rim of the bell and the wall of the tube, being left for the passage of the gas.—L. E.

Alcohol; Process and apparatus for purifying crude —. E. G. Hager. Fr. Pat. 395,971, Nov. 5, 1908.

SEE GER. Pat. 200,980 of 1907; this J., 1908, 993.—T. F. B.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, AND DISINFECTANTS.

(A.)—FOODS.

Wheat flour, dough, and fermented dough; Sugar content of fine —, and diastatic power of wheat flour. H. J. von Liebig. Landw. Jahrb., 1909, 38, 251—271. Chem. Zentr., 1909, 1, 1256—1257.

The sugars present in wheat flour are dextrose and sucrose, the respective quantities being 0.1—0.4 and 1—1.5 per cent. calculated on the dry substance. By the action of a diastatic enzyme, maltose is formed on digesting the flour with water and also in the dough. The production of reducing sugar in the dough proceeds vigorously at a favourable temperature: for example, after 14 hours at 30—40° C., 4.6 per cent. of reducing sugar (reckoned as dextrose) were formed. The sucrose content, on the other hand, shows little variation in the dough. The increase of the dextrose (maltose) content of the dough gradually slackens considerably. When dough prepared from the finest quality of flour was fermented at 30° C. with the usual quantities of yeast, water, and salt, the loss of sugar amounted to from 1.42 to 2.05 per cent. in 2 hours, the reducing sugar being acted upon much more strongly than the sucrose. The diastatic power (Lintner) of wheat flour was about one-third of that of an average malt in the case of dark coarse flours, and about one-seventh in the case of the finest "extract flours." The extracts to be used for determining the diastatic power of wheat flours, should be prepared by making the flour into dough, and kneading this with water to separate the starch from the gluten. The values obtained represent only the action on dissolved starch. The starch-liquefying power of the diastase of wheat flour is quite insignificant compared with that of malt diastase. The author suggests that the wheat diastase is a weak so-called translocation-diastase which becomes active in the dough. (See also J. L. Baker and H. F. E. Hulton, this J., 1908, 368.)—A. S.

Benzaldehyde in almond flavouring extract; Determination of —. W. Denis and P. B. Dunbar. J. Ind. and Eng. Chem., 1909, 1, 256—257.

The method is based on the precipitation of benzaldehyde as its phenylhydrazine by means of a reagent composed of 1 c.c. of phenylhydrazine, 1.5 c.c. of glacial acetic acid, and 20 c.c. of water, prepared immediately before use. Two 10 c.c. portions of the almond extract are treated respectively with 10 c.c. and 15 c.c. of the reagent in stoppered flasks, and after shaking, the mixtures are allowed to stand over night. 200 c.c. of water are then added to each flask, the precipitates collected in Gooch crucibles on asbestos, washed with cold water and then with 10 c.c. of 10 per cent. alcohol, and dried *in vacuo* over sulphuric acid or for 3 hours at 70—80° C. in a vacuum oven. It is advisable to make the second determination with 15 c.c. of reagent, because, although most almond extracts contain only about 1 per cent. of oil of bitter almonds, occasionally samples are met with containing as much as 6 per cent. of benzaldehyde. The method gives results corresponding to 97—99 per cent. of the theoretical ones, and the accuracy is not affected by the presence of benzoic acid or nitrobenzene.—A. S.

Casein; Note on the hydrolysis of — with hydrochloric and sulphuric acids. Z. H. Skraup and W. Türk. Monatsh. Chem., 1909, 30, 287—288.

F. KITSCHER has stated that by the hydrolysis of casein with sulphuric acid, much less glutamic acid is produced than when hydrochloric acid is used. The authors have carried out the operation on the one hand by boiling casein for 6 hours with six times its quantity of fuming hydrochloric acid and on the other by boiling for 18 hours with nine times the quantity of 33 per cent. sulphuric acid. In each case the amount of glutamic acid was about the same: 100 grms. of casein gave (1), 22.3 grms. of the crude hydrochloride, and (2), 20.3 grms.—J. C. C.

(B.)—SANITATION; WATER PURIFICATION.

PATENTS.

Water purifying apparatus. F. C. Pulsford, Leicester. Eng. Pat. 12,711, June 13, 1908.

THE apparatus is essentially a measuring device which delivers definite volumes of the crude water to chemical tanks; the solutions from the latter are then mixed with the main volume of the water, which is also measured by the apparatus and delivered into the mixing tank. The apparatus consists of a tank divided into compartments; the measuring vessel is mounted on a spindle in this tank and is also divided into a number of compartments connected to each other by means of suitable pipes or tubes. The water is delivered into the central or largest compartment of the measuring vessel, the smaller compartments being filled at the same time by the water flowing through the connecting pipes. When the vessel is full, it tips and delivers the contents of its various compartments into corresponding compartments in the outer tank. The water from the smaller compartments, which may be of any predetermined capacity, is conducted to the tanks containing chemicals and thence to the mixing tank, whilst the bulk of the water is delivered directly to the mixing tank. By means of a lever and valve, the supply of water is cut off when the measuring vessel tips, but is turned on again when the vessel automatically assumes its normal or upright position. The measuring vessel may also have the form of a double tipping arrangement, the compartments on one side being filled while the ones on the other side are discharging. The volume of water measured each time the vessel is filled and discharged may be regulated by means of adjustable weights fitted to the sides of the vessel.—W. P. S.

Raising sewage or other liquid by air pressure. J. B. Allott and A. M. Philps, Nottingham. Eng. Pat. 13,655, June 27, 1908.

THE claim is for improvements in the apparatus described in Eng. Pat. 28,789 of 1904, and consists in arranging the air inlet and exhaust valves of a pair of "ejectors" so that only one is emptied at a time, and that if the one that is being filled becomes full before the other is empty, compressed air is admitted to the former to stop the inflow of sewage and to prevent it rising up to the level of the valves.—W. H. C.

(C.)—DISINFECTANTS.

PATENT.

Manufacture of copper nitrate. Fr. Pat. 395,806. See VII.

XIX.—PAPER, PASTEBOARD, &c.

PATENTS.

Paper; Method and means of treating — A. M. Meinke, Winchester, Mass., Assignor to T. N. Tripp, Lynn, Mass. U.S. Pat. 916,469, Mar. 30, 1909.

THE process consists in laying down the fibres on the surface of the partially dried, but uncalendered, web, first on one side and then on the other. The web is subsequently compressed. In the apparatus described, an ironing device,

having a curved surface for engaging the web, is situated adjacent to the drying cylinders, and means are provided for stretching the web and for drawing it over the surface of the ironing device.—W. P. S.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

Laudanosine; Complete synthesis of — A. Pictet and M. Finkelstein. Compt. rend., 1909, 148, 925—927.

WHEN sodium hypobromite acts upon dimethylhydrocaffeic amide, homoveratrylamine is produced. Starting from eugenol, homoveratryl chloride was obtained. These substances condense under the action of sodium hydroxide to form homoveratryl-homoveratrylamine, $(\text{CH}_3\text{O})_2\text{C}_6\text{H}_3\text{CH}_2\text{CH}_2\text{NHCOCH}_2\text{C}_6\text{H}_3(\text{OCH}_3)_2$. When this substance is treated with phosphorus pentoxide, a molecule of water is removed, with the formation of dihydropapaverine. The dihydropapaverine is treated with methyl chloride and reduced with tin and hydrochloric acid, when racemic methyltetrahydropapaverine is produced. This base has been resolved by Pictet and Athanasesco (this J., 1900, 1036, 1139) into its optical isomerides, of which the dextro-rotatory modification is identical with natural laudanosine.—F. SHDN.

Ketones; Catalytic preparation of — J. B. Senderens. Compt. rend., 1909, 148, 927—929.

ORDINARY ether can be prepared in a good yield by the catalytic action of aluminium oxide (see this J., 1909, 219). Besides this, the only other ether which can be made to give a satisfactory yield by this method is dimethyl ether. Acetone can be made by passing the vapour of acetic acid over precipitated aluminium oxide heated to 300°—380° C. (this J., 1908, 185). Fairly good yields of the corresponding ketones are obtained in a similar manner from propionic and butyric acids, but only a poor yield from isobutyric acid. Ethyl acetate passed over aluminium oxide heated to 380°—420° C. gives a good yield of acetone, together with some ethylene. Thorium oxide, which is a poor catalyst for the production of ethers, gives good results for the preparation of ketones. The thorium oxide must be heated to 380°—420° C. while the acid vapours are passed over. Diethylketone, dipropylketone, and diisopropylketone were prepared in this way. Formic acid gives formaldehyde when passed over heated aluminium oxide. If thorium oxide heated to 250° C. is used, a considerable amount of carbon dioxide is produced, with some formaldehyde, and unchanged acid.—F. SHDN.

Diphenylamine; Determination of — as tetrabromodiphenylamine. W. Dreger. Z. ges. Schiess- und Sprengstoffw., 1909, 4, 123.

DIPHENYLAMINE in alcoholic solution reacts with bromine to form tetrabromodiphenylamine:

THIS bromo-derivative is insoluble in water, sparingly soluble in alcohol, readily soluble in benzene, xylene, chloroform, and ethyl acetate, especially on warming; it melts at 102° C., and crystallises in reddish needles having a silky lustre. For the determination of diphenylamine in the commercial product, the sample is dissolved in alcohol, or if already in ethereal solution, the ether may be driven off by adding alcohol and warming. Excess of bromine is then added, drop by drop, with constant stirring. The solution is next mixed with twice its volume of water and the whole boiled until the alcohol and excess of bromine are driven off and the bulk is reduced to one-half—constant stirring is needful. The precipitate of

tetrabromodiphenylamine is transferred to a funnel, or Gooch crucible, connected to a water pump, and washed with warm water to remove the last traces of alcohol and bromine, and lastly dried at 98°—100° C. until of constant weight. Smaller quantities may be estimated by evaporating to dryness in a previously weighed glass vessel. If it be desired to determine the diphenylamine contained in gelatinised nitro-cotton, the nitro-compound is gradually decomposed by means of soda lye in a capacious flask. The flask is closed by a doubly perforated stopper fitted with a stoppered funnel, and a bent tube attached to a condenser, which communicates with a suitable receiver. The free diphenylamine and any camphor that may be present are carried into the receiver which contains ether. The distillate is well shaken with common salt; the ether completely dissolves the diphenylamine and any camphor, and the determination is then completed as before indicated.—J. W. G.

Tartaric acid; Determination of — in commercial products. P. Carles. J. Pharm. Chim., 1909, 29, 381—382.

SENSITIVE litmus paper is the most satisfactory indicator for the acidimetric titration of tartaric acid. According as the standard alkali employed may be caustic potash or soda, strips of sensitive litmus paper are plunged half-way in solutions (1:120) of either pure neutral potassium tartrate, or of Rochelle salt. The strips show a delicate blue shade in the immersed portion, which is the neutral tint to be worked to. In the solution of bitartrate to be titrated, similar bands are immersed in the same way, and phenolphthalein is also used as a rough indicator to regulate the addition of the standard alkali. When the blue shade appears in the moistened litmus paper, the liquid is boiled, and then tested with a fresh band. When the shade of this and of the control band are identical, the reading is taken.—J. O. B.

Bismuth poisoning and a non-toxic substitute for bismuth for use with Röntgen rays. L. Lewin. Münch. med. Wochenschr., 1909, 56, 643—645. Chem. Zentr., 1909, 1, 1345.

THE author describes the symptoms of bismuth poisoning and argues against the designation of bismuth subnitrate poisoning as a nitrite poisoning, pointing out that similar symptoms to those produced by bismuth subnitrate can also be caused by other compounds of bismuth, for example, bismuth-potassium tartrate, bismuth subgallate (dermatol), and bismuth oxyiodide gallate (airol). The substitution of other bismuth compounds, e.g., the carbonate, for bismuth subnitrate in working with Röntgen rays is thus no safeguard against poisoning. [In preparing radiographs of interior parts or organs of the body, bismuth compounds have been administered in order to outline such parts before exposure to the rays.] It has been found that an efficient, non-toxic substitute for bismuth salts in such work is the magnetic oxide of iron.—A. S.

Iodine pentoxide; Preparation of pure —. M. Guichard. Compt. rend., 1909, 148, 923—925.

ALTHOUGH the solubility of iodic acid in water is very great, in nitric acid of sp. gr. 1.4 it is only 0.67 gm. per 100 grms. of solvent. Hence if nitric acid is added to an aqueous solution of iodic acid, and the liquid concentrated, iodic acid is deposited in the form of fine crystals. Impure iodic acid can be purified by crystallisation from nitric acid. A good yield of iodic acid can be obtained by the following process. A horizontal tube is connected to the neck of a retort, and filled with iodine moistened with fuming nitric acid. A mixture of fuming nitric acid and phosphorus pentoxide is gently heated in the bulb of the retort, when nitrogen pentoxide passes over the iodine, converting it into iodic acid. The contents of the tube are dissolved in water, evaporated, and the residue dried at 220° C. 100 grms. of fuming nitric acid produce 20 grms. of iodic pentoxide, a much greater yield than has been obtained hitherto with the same reagents.—F. SHDN.

PATENTS.

p-Ethoxyphenylamidomethyl alkaline sulphites and process of making same. R. Lepetit, Garressio, Italy. Eng. Pat. 21,389, Oct. 9, 1908.

p-ETHOXYPHENYLAMINOMETHYL sulphites are obtained by heating *p*-phenetidine with formaldehyde and an alkali bisulphite, in presence of excess of 95 per cent. alcohol and only sufficient water to dissolve the product when boiling. Thus, 1000 grms. of *p*-phenetidine are dissolved in 3 litres of 95 per cent. alcohol, 571 c.c. of 40 per cent. formaldehyde are added and then 1420 c.c. of sodium bisulphite solution (38° B.); the mixture is heated to 60° C., one litre of warm water is added, and the whole is boiled for a short time; after 24 hours the product is filtered off, and is obtained quite pure. It is easily soluble in hot water, slightly soluble in alcohol, insoluble in ether or chloroform. Acids precipitate the free acid from aqueous solutions of the salt. The salts possess the antineuralgic and antipyretic properties of *p*-phenetidine, without its toxic effects.—T. F. B.

Tartaric acid; Manufacture of —. G. F. Berry, London. Eng. Pat. 22,029, Oct. 17, 1908.

THE raw material (potassium bitartrate) is ground to powder and added to a 50 to 60 per cent. cold solution of calcium chloride. After stirring well, the mass is neutralised with chalk or milk of lime and again agitated for about four hours. After settling, the clear liquid containing calcium and potassium chlorides is run off, and the residue of calcium tartrate is washed with cold water and converted into tartaric acid and calcium sulphate by means of sulphuric acid. The tartaric acid solution thus obtained is decolorised by animal charcoal, freed from any lead and arsenic it may contain by precipitating these metals as sulphides, and after filtering is purified by crystallisation.—O. R.

Guaiaicol compounds. F. Hoffmann-La Roche and Co., Bale, Switzerland. Eng. Pat. 24,072, Nov. 10, 1908. Under Int. Conv., Oct. 5, 1908.

CLAIM is made for the production of a new compound, hexamethylenetetraminetrignuaicol, which crystallises in brilliant needles becoming soft above 80° C., and melting to a turbid liquid at about 95° C. It is readily soluble in alcohol and chloroform, and yields guaiaicol on distillation in a current of steam. It may be obtained by the interaction of guaiaicol and hexamethylenetetramine in concentrated aqueous solution, or by treating a solution of formaldehyde with an ammoniacal solution of guaiaicol containing the necessary amount of ammonia to form hexamethylenetetramine.—C. A. M.

Formic aldehyde-containing composition, and process of making the same. H. S. Blackmore, Mount Vernon, N.Y. U.S. Pat. 917,706, April 6, 1909.

THE composition consists of formaldehyde, a fixed vegetable oil such as maize oil, and a medicating agent, such as eucalyptol.—A. T. L.

Anhydromethylenecitric acid; Preparation of the esters of —. Farbenfabrik vorm. F. Bayer und Co. Fr. Pat. 395,447, Oct. 17, 1908. Under Int. Conv., Jan. 3, 1908.

CLAIM is made for the production by the usual methods of esters of anhydromethylenecitric acid. The methyl ester melts at 76° C., the ethyl ester at 55° C., and the amyl ester at 52°—53° C.—F. SHDN.

Phenoxydialkylaminopropanols and their acyl derivatives; Preparation of —. Etab. Poulenc Frères and E. Fourneau. 1st and 2nd Additions, dated May 2, 1908, to Fr. Pat. 395,470, Dec. 28, 1907. (See this J., 1909, 442.)

THE process described in the principal patent (*loc. cit.*) for the production of phenoxydialkylaminopropanols, has been extended to the following substances. *p*-Cresol is condensed with dichlorhydrin, and the product treated with dimethylamine. *p*-Methylphenoxydimethylaminopropanol thus produced, is a colourless basic oil, boiling

at 175°—176° C. at 10 mm. Starting with thymol instead of *p*-cresol, 1-methyl-4-propylphenoxymethylaminopropanol is produced, which boils at 177° C. at 11 mm. Guaiacol gives rise to 1-methoxy-2-phenoxydimethylaminopropanol, which crystallises from ether and melts at 60°—61° C. Naphthoxydimethylaminopropanol melts at 81°—82° C., and boils at 217° C. at 17 mm. *p*-Nitrophenoxymethylaminopropanol crystallises from 60 per cent. alcohol in yellow leaflets, melting at 81°—82° C., and forms a picrate melting at 153° C. Phenoxypropanol-aniline is prepared by heating together aniline and phenoxypropane oxide, and crystallises from alcohol in fine needles melting at 57° C. Using phenetidine in place of aniline, phenoxypropanolphenetidine is produced, which crystallises from dilute alcohol in fine white needles melting at 95° C. Methylphenoxypropanolphenetidine crystallises from dilute alcohol and melts at 91° C. —F. SHDN.

Colloidal silver or silver oxide; Process for obtaining preparations containing —. L. Sensburg. Ger. Pat. 208,189, July 30, 1907.

PREPARATIONS containing colloidal silver or silver oxide are obtained by treating aqueous solutions of silver salts with alkaline solutions of such tannin-substances (catechu, catechin, catechu-tannic acid, gambier, kino, etc.) as yield protocatechuic acid and phloroglucinol when fused with potassium hydroxide. The colloidal solutions thus produced are freed from alkali and salts by dialysis, and then evaporated to dryness, preferably in a vacuum. The products are soluble in water and are valuable therapeutically, possessing both the antiseptic properties of colloidal silver and the astringent properties of tannin-substances.—A. S.

Eugenol- and isoeugenol-acetamide; Process for preparing N-substituted aminomethyl compounds of —. A. Einhorn. Ger. Pat. 208,255, Aug. 8, 1907.

NEW compounds, which are of value as local anaesthetics, are produced (1), by the action of formaldehyde and secondary bases on eugenol- or isoeugenol-acetamide, $\text{CH}_3\text{O.C}_6\text{H}_3(\text{C}_2\text{H}_5)\text{O.CH}_2\text{CO.NH}_2$; (2), by the action of secondary aliphatic bases on the methylol derivatives of the above compounds. The aminomethyl group attaches itself to the amino group of the eugenol derivative.—T. F. B.

p-Aminophenol and methyl-p-aminophenol; Process for separating —. Chem. Fabr. auf Actien, vorm. E. Schering. Ger. Pat. 208,434, Aug. 29, 1907.

"METOL," the sulphate of methyl-*p*-aminophenol, always contains *p*-aminophenol sulphate as an impurity. In order to separate the two bases a solution of their salts is agitated with an aldehyde, such as benzaldehyde, preferably in slightly acid solution, *e.g.*, with acetic acid. If benzaldehyde is used, the benzyldine-*p*-aminophenol is completely precipitated after a short time, and filtered off, and the excess of benzaldehyde is removed by boiling. —T. F. B.

1-Aryl-2,4-dialkyl-5-halogenmethyl-3-pyrazolones; Process for preparing —. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 208,593, Feb. 5, 1908. Addition to Ger. Pat. 206,637, Oct. 3, 1907.

THE process described in the principal patent for preparing 1-aryl-2,4-dialkyl-3-halogenmethyl-5-pyrazolones (this J., 1909, 325) is applied to preparing the isomeric 1-aryl-2,4-dialkyl-5-halogenmethyl-3-pyrazolones from 1-aryl-2,4-dialkyl-5-methyl-3-pyrazolones.—T. F. B.

Mesityl oxide; Process for preparing —. M. Kohn. Ger. Pat. 208,635, Nov. 16, 1907.

ACETONE is condensed by means of alkalis to diacetyl alcohol, and the latter is heated with a very small quantity of some dehydrating agent (*e.g.*, one per cent. of sulphuric acid by volume).—T. F. B.

1-Alkyl-2-alkoxy-pyrimidine derivatives; Process for preparing —. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 208,639, April 25, 1908.

2-ALKYLOXYPYRIMIDINES are readily alkylated in the 1-position, *e.g.*, by treatment with a dialkyl sulphate in presence of alkali. The products may be used in the preparation of 1-alkylpurine derivatives.—T. F. B.

Aminoarylsulphonic acids; Manufacture of acid derivatives of —. Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on Main, Germany. Eng. Pat. 17,139, Aug. 14, 1908. Under Int. Conv., Aug. 19, 1907.

SEE Fr. Pat. 392,857 of 1908; this J., 1909, 107.—T. F. B.

Mercury salts of p-aminophenylsulphonic acid; Process for producing —. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 396,192, Nov. 12, 1908. Under Int. Conv., Nov. 19, 1907.

SEE U.S. Pat. 914,408 of 1909; this J., 1909, 442.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENTS.

Photographic sensitive surfaces. E. S. Donisthorpe. London. Eng. Pat. 5641, March 13, 1908.

SENSITIVE emulsions are applied to flexible, opaque supports, such as black paper or pigmented celluloid.—T. F. B.

Photographic sensitive surfaces. F. W. Donisthorpe, Bath. Eng. Pat. 7087, March 31, 1908.

AN emulsion is coated on an opaque, rigid support, such as black glass or ebonite. The negatives can be printed by any of the contact processes not requiring transmitted light.—T. F. B.

Film for cinematograph and like apparatus; Manufacture of —. Soc. Anon. des Plaques et Papiers Photographiques A. Lumière et ses fils, Lyons, France. Eng. Pat. 16,114, July 29, 1908. Under Int. Conv., June 3, 1908.

A LAYER of gelatin or similar non-inflammable colloid, which is coated with a sensitive emulsion, is supported by a film of collodion, celluloid, etc., during the photographic operations, to ensure the gelatin film, when separated subsequently, being of the same dimensions throughout its length.—T. F. B.

Colour plates or screens for colour photography; Manufacture of —. J. H. Christensen, Holte, Denmark. Eng. Pat. 20,971, Oct. 5, 1908. Under Int. Conv., Jan. 25, 1908.

COLOUR screens are formed of small particles produced by the emulsification of a coloured medium in a liquid. For example, a solution of shellac or other resin in spirit is divided into three parts, which are coloured with the colours of which it is desired to compose the screen. These coloured solutions are each "emulsified" by shaking

them with turpentine: after standing some time, the larger particles settle, and it is possible to draw off portions of each mixture with particles of approximately the same size. These are now spread on a glass or other support, either separately or after mixing together, and the whole is heated gently or subjected to pressure to amalgamate the particles and produce a homogeneous layer. A layer of sensitive emulsion may now be applied to the screen. The resin may be replaced by gelatin, gum, or albumin.

—T. F. B.

Films: Process for the manufacture of continuous — M. Ratignier and H. Pervillac et Cie. Fr. Pat. 395,665, Jan. 4, 1908.

ANY of the solutions employed in the manufacture of artificial silk may be used for making films by this process, which is characterised by the fact that the film is kept in a stretched condition throughout its manufacture, thus avoiding shrinkage and yielding a product having a very smooth surface and a high degree of transparency. From a reservoir, in which the level of the liquid is maintained constant, the solution flows out on to the surface of a slowly revolving drum. The flow and the width of the film are regulated by means of an adjustable slide in the wall of the reservoir, which is set to leave a space of a desired dimension between its lower edge and the surface of the drum. The lower part of the drum is surrounded by a mantle in which the coagulating liquid is circulated. The film after passing through this liquid is detached from the drum and, its edges engaging with two parallel endless bands which serve to keep it in position, is led around a number of perforated drums upon which the operations necessary to ensure complete coagulation, washing, etc., are carried out, after which the film is dried upon a cylinder.

Pyrophoric substances. Fr. Pat. 396,198. See II.

Separating p-aminophenol and methyl-p-aminophenol. Ger. Pat. 208,434. See XX.

XXII.—EXPLOSIVES, MATCHES, &c.

Explosives: Chlorate and perchlorate — Girard and Laroche. Monit. Scient., 1909, 23, 217–252.

RECENT methods of manufacture have enabled a class of chlorate and perchlorate explosives to be produced—notably those of the Street type known in France as cheddites, which are safe to manufacture, store, handle, and use. Ammonium perchlorate being stable and yielding gaseous decomposition products is, in the opinion of the authors, well adapted to be used to a greater extent than hitherto. It does not begin to decompose until a temperature of 135° C. is attained, and then only with extreme slowness and after long heating at that temperature as follows: $\text{NH}_4\text{ClO}_4 = 2\text{H}_2\text{O} + \text{O}_2 + \text{Cl} + \text{N}$. The rate of decomposition increases with rise of temperature, but is regular throughout. The general method of preparing cheddites is as follows:—Castor oil is heated to 70° C.,

by steam in a double-walled vessel. Mononitronaphthalene, which may be used with, or replaced by, another nitro-derivative, is added, and then the melted and homogeneous mass is mixed with the requisite proportion of warm, dry, and powdered sodium or potassium chlorate with a wooden spatula. 25 kilos. of explosive can be made in about 7 minutes. The process is completed by pouring the material on to a wooden table, allowing it to cool to 30°–35°, and then rolling it with a wooden roller. The rolling process is repeated when the mass is cold. The finished explosive assumes the form of small grains. Two individuals of the class, officially designated Type 60 and Type 41, were experimented on. Their composition was as follows:—

	Type 60.	Type 41.
Potassium chlorate.....	80	80
Mononitronaphthalene	12	12
Castor oil	6	8
Picric acid	2	—

Effect of shock.—In this case the following standard explosives were used for purposes of comparison:—No. 1 dynamite (75 per cent. of nitroglycerin), gelatin-dynamite (*Dynamit-gomme*), smokeless powder, French mining powder, French sporting powder. The last two were in either grains or powder, as were also the cheddites. In each case 8 grms. were uniformly distributed over a circular steel anvil of 140 mm. diam. To ascertain whether shock or combustion were propagated, a train 10–20 cm. long was laid from the explosive along the anvil or on sand. Shock was communicated by a 35-kilo. weight which was allowed to fall from various heights either directly on the explosive layer, or on a cylinder of the same diameter as the anvil, weighing 6 kilos., and resting on the layer. From the figures given it appears that when decomposition took place, the standard explosives detonated or burnt with more or less violence with propagation in the majority of cases, while the cheddites detonated feebly without propagation of either shock or combustion. The stability of cheddites is increased by prolonged storage: they are quite insensible to any shock likely to occur during manufacture or handling. They can only be usefully exploded by fulminate. *Resistance to friction.*—100 grms. each of cheddites No. 60 and No. 41 were spread over a steel surface. A bullet coated with German silver was fired from a gun of 8 mm. bore inclined at 10° to the horizontal. 25 grms. burnt with feeble detonation in the track of the bullet. *High temperatures and flame* cause cheddites to burn more or less rapidly. There is no detonation with large or small masses. When burnt under very varied conditions the fire was easily extinguished by a small amount of water. *Resistance to the action of strong sulphuric acid.*—Masses of a few grms. to 50 kilos. weight burnt briskly when acid of 66° B. was used; there was no detonation even when the substance was enclosed in wooden cases. *Resistance to low temperatures.*—On cooling to –20° C., the plasticity was unaltered, and the sensitiveness to shock was not increased. *Resistance to heating.*—Heated for 8 days at a temperature of 90°–100° C., the cheddites remained soft. At 200° the oil decomposed, the nitro-compounds were volatilised, and the mass dried and blackened. At the decomposing temperature of the chlorate, the explosives deflagrated sharply. They safely withstood a prolonged temperature of 120° C., and showed resistance to water vapour and water. Eschweiler has tested cheddites having the following composition:—

	Type 41 N.	Type 60 N.
Sodium chlorate	80	80
Dinitrotoluene	—	2
Nitronaphthalene	12	13
Castor oil	8	8

The results obtained by tests analogous to those already given show them to have the same qualities as Nos. 41 and 60. All four types are said to stand the official

English heat test for a longer period than is officially demanded. A list of chlorate and perchlorate explosives formerly proposed and patented, is appended. It contains details of two ammonium perchlorate explosives which have the following composition:—

	Type C.	Type B.
Ammonium perchlorate.....	50	82
Sodium nitrate.....	30	—
Dinitrotoluene.....	15	13
Castor oil.....	5	5

“B,” though more powerful, should not be used in mine galleries as ammonium perchlorate yields hydrochloric acid gas by explosive decomposition, and to prevent this sodium nitrate should be admixed.—J. W. G.

Determining diphenylamine [e.g., in gelatinised nitro-cotton]. Dreger. See XX.

Explosives in coal mins. Chem. and Drug., April 24, 1909. [T.R.]

UNDER the Coal Mines Regulation Act, 1896, a Secretary of State, on being satisfied that any explosive is or is likely to become dangerous, may by order prohibit the use of it in any mine, either absolutely or conditionally. A new order declares that the order of December 17, 1906, “shall take effect as if the explosives named and defined in the schedule to this order were named and defined in the first schedule to that order.” The explosives mentioned are amasite, dominite, and St. Helen’s powder, and in each case the order sets forth the conditions upon which these may be used. The Home Secretary also gives notice that, by an Order dated recently, he has removed the explosives saxonite and geloxite from the list of permitted explosives for use in mines to which the Explosives in Coal Mines Order of December 17, 1906, applies. The Order takes effect as from Monday, May 3, inclusive.

PATENT.

Explosive compounds and their manufacture. G. Lezinsky. Fr. Pat. 395,635, Oct. 24, 1908. Under Int. Conv., Nov. 1, 1907.

SEE U.S. Pat. 909,915 of 1909; this J., 1909, 384.—T. F. B.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS.

PATENTS.

Viscosity of liquids; Apparatus for the determination of the —. W. Graaff and Co., Ges.m.b.H., and H. Mikorey. Ger. Pats. 205,235, March 17, 1905; 207,177, Feb. 8, 1906; and 207,178, May 1, 1906.

(1). A PROPELLER-SCREW is rotated in the liquid of which the viscosity is to be determined, and the driving-power developed by the screw is measured by fitting the frame carrying the propeller-shaft with a pointer and scale, the pointer coming to rest when the driving-power of the screw is balanced by the resistance of the frame. Special claim is made for combining the screw, frame, pointer, and scale in a connected whole, which can be used with liquids contained in different kinds of receptacles. (2). The turbine which drives the propeller-screw is fixed on the propeller-shaft, but is movable in its casing in an axial direction. (3). Instead of a turbine, an electric motor is used to drive the propeller-screw, the armature of the motor being fixed to the propeller-shaft.—A. S.

INORGANIC—QUANTITATIVE.

Silver: Determination of — iodometrically, using potassium chromate as precipitant. F. A. Gooch and R. S. Bosworth. Amer. J. Sci., 1909, 27, 302—304.

UTILISING the fact that silver may be completely precipitated with a sufficient excess of potassium chromate, even

in the presence of nitric acid, the authors have devised a volumetric method of determining this metal, which consists in dissolving the precipitated chromate in ammonia, reprecipitating by boiling to a small volume, and then titrating iodometrically, either the chromate ion combined with the silver, or that of the excess of potassium chromate remaining after precipitation with a known amount of this reagent.—F. SOBX.

Mercury: Determination of — by electro-analysis with a gold cathode. F. M. Perkin. Faraday Soc., March 30, 1909. [Advance proof.]

DETERMINATION of mercury electrolytically with a gold cathode gives somewhat high results, and it is considered that a gold electrode cannot be satisfactorily employed for analytical purposes. A rotating silver electrode also gives values which are too high. Mercury is best deposited upon a mercury cathode, and this is done very rapidly if a rotating anode be used.—F. SOBX.

Arsenic; Volumetric determination of small amounts of —. L. W. Andrews and H. V. Farr. Amer. J. Sci., 1909, 27, 316—320.

ABOUT 20 c.c. of the solution to be examined are mixed with 50 c.c. of a solution made by dissolving 20 grms. of stannous chloride crystals and 40 grms. of tartaric acid in 1 litre of 40 per cent. hydrochloric acid, and the mixture is maintained for 2—3 hours at 35°—40° C. in a well-stoppered bottle, until the precipitated arsenic has completely subsided. The precipitate is transferred to an asbestos filter with the aid of a little strong hydrochloric acid, free from chlorine, and washed, and then asbestos and precipitate are returned to the bottle with an amount of N/100 or N/10 iodine solution, 10—100 per cent. above that indicated by the equation, $\text{As} + 5\text{I} + 7\text{NaHCO}_3 = \text{Na}_2\text{HAsO}_4 + 5\text{NaI} + 7\text{CO}_2 + 3\text{H}_2\text{O}$; enough of a 5 per cent. solution of sodium bicarbonate or sodium phosphate is added to maintain neutrality throughout the reaction, and, when all the arsenic is dissolved, the excess of iodine is titrated with N/100 or N/1000 arsenite solution. For quantities of arsenic smaller than 0.5 mgrm., N/1000 solutions may be employed, but in this case a correction must be made for the amount of iodine required to produce the end-reaction. The process is said to be accurate, fairly rapid, and widely applicable. It is suggested that mirrors obtained by the Marsh method might be accurately determined by titration with iodine.—F. SOBX.

Vanadic and arsenic acids and also vanadic and antimonie acids; Determination of —, in the presence of one another. G. Edgar. Amer. J. Sci., 1909, 27, 299—301.

VANADIC and arsenic acids may be determined in the presence of each other by a process of differential reduction. One portion of the solution containing the acids is boiled with tartaric or oxalic acid, until the blue colour of vanadium tetroxide indicates complete reduction; the solution is then cooled, nearly neutralised with potassium bicarbonate, and an excess of standard iodine solution is added; this is followed by an excess of bicarbonate, and the solution is allowed to stand half an hour, when the excess of iodine is removed with standard arsenious acid and the solution titrated with iodine. Another portion of the solution, acidified with sulphuric acid, is heated in a closed pressure flask for 1 hour on the steam bath with strong sulphurous acid solution; the excess of sulphur dioxide is removed by boiling in a current of carbon dioxide, and the solution is then cooled, nearly neutralised with potassium bicarbonate, iodine added, and the process finished as before. In the first portion the vanadium is reduced to tetroxide, the arsenic acid being unaffected, but in the second portion both vanadium and arsenic are reduced. Re-oxidation takes place according to the equation, $\text{As}_2\text{O}_3 + \text{V}_2\text{O}_4 + 3\text{I}_2 + 3\text{H}_2\text{O} = \text{As}_2\text{O}_5 + \text{V}_2\text{O}_5 + 6\text{HI}$. Antimonie and vanadic acids are determined by a similar process.—F. SOBX.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Gases occluded in the lavas of the last eruptions of Mont Pelée and Vesuvius; Analysis of —. Grossmann. Compt. rend., 1909, 148, 991–992.

THE gases, which were obtained by heating the finely powdered rocks *in vacuo*, were found to have the following percentage composition by volume at 0° C. and 760 mm. pressure:—

	Mont Pelée (1902).		Vesuvius (1906).	
	Andesite from the summit.	Pumice, 9th July.	Lava from Boscotrecase.	Lapilli thrown upon Ottajano.
Volume of gas from 100 grms. of rock . . .	8 c.c.	2.5 c.c.	66 c.c.	65 c.c.
Carbon dioxide . . .	85.00	78.01	24.6	58.1
Oxygen	—	—	1.5	2.41
Nitrogen	5.42	6.61	9.2	17.6
Hydrogen	5.02	2.12	50.6	2.41
Carbon monoxide	7.46	11.11	11.1	17.2
Methane	—	—	2.6	—
Residual gas	—	2.12	1.5	1.4

Neither acetylene, ethylene, propylene, nor benzene was found in the samples, but traces of helium and argon were discovered in the Mont Pelée pumice and the Boscotrecase lava respectively, rare gases being absent in the case of the Ottajano lapilli. The great difference in composition between the gases from the Vesuvian products is remarked upon and regarded as probably supporting the contention of Lacroix that the lapilli which fell upon Ottajano during the 1906 eruption were composed of old volcanic material and did not represent the actual lava flow of that date.

—W. E. F. P.

Fungi; Chemistry of the higher —. Part III. Diastases of fungi. J. Zellner. Monatsh. Chem., 1909, 30, 231–246. (Compare this J., 1908, 94.)

THE author has studied the chemical action of the enzymes contained in 19 species of wood fungi, by observing their action on potato starch. He finds that:—(1) Amylolytic enzymes are generally contained in wood fungi. (2) The enzymes retain their activity in the dried fungi for a considerable time. (3) Their action is partly or completely inhibited by the presence of even a small quantity of inorganic acids or bases, but dilute organic acids give rise to an increased action. (4) The diastatic degradation proceeds most rapidly between 40° and 60° C.; the optimum temperature is about 50° C., and the action is stopped at 70° C. (5) Compared with malt, the diastatic power of the fungi is very small. (6) The products of the enzymatic hydrolysis are primarily substances of the dextrin group, and finally, in addition to dextrin, chiefly dextrose. Maltose could not be detected with certainty. (7) Other carbohydrates (such as inulin, arabinose) are not attacked by the ferments.—J. C. C.

Sugar; Decomposition of — during the respiration process. P. B. Jensen. Ber. Deutsch. Botan. Ges., 1908, 26, 666. Chem.-Zeit., 1909, 33, Rep. 153.

IF during the alcoholic fermentation of dextrose, hydroxylamine hydrochloride be added to the liquid, small quantities of the oxime of dihydroxyacetone are formed. Also, after the fermentation is complete, dihydroxyacetone can be identified as its methylphenylosazone by addition of acetic acid and methylphenylhydrazine. Dihydroxyacetone itself can be fermented, with production of alcohol and carbon dioxide. According to the author, alcoholic fermentation may be divided into two stages, the decomposition of dextrose with formation of dihydroxyacetone, and the splitting-up of the latter into alcohol and carbon dioxide. Hence zymase must consist of two different enzymes, *dextrase* and *dihydroxyacetonease*. If fermentation of sugar be carried out in glycerol solution, the dextrase alone is active, and dihydroxyacetone is the final product. Dihydroxyacetone can be decomposed by means of oxydase, but no alcohol is produced. By addition of oxydase to a fermenting sugar solution, the normal process of respiration of plants can be imitated. Dihydroxyacetone is produced from the dextrose by the action of the dextrase of the yeast, and is then decomposed by the oxydase with formation of carbon dioxide and water.—A. S.

New Books.

CHEMICAL TECHNOLOGY AND ANALYSIS OF OILS, FATS, AND WAXES. By Dr. J. LEWKOWITSCH, M.A. Fourth Edition, entirely rewritten and enlarged. Three volumes. Macmillan and Co., Limited, St. Martin's Street, London. 1909. Price £2 10s.

THREE 8vo volumes, containing:—VOL. I.: 540 pages of subject matter, and an appendix with additional matter of two pages. The volume contains 54 illustrations. VOL. II.: 786 pages of subject matter, and an appendix with additional matter of 21 pages, followed by indexes of botanical names and zoological names for the entire work. There are 20 illustrations. VOL. III. 379 pages of subject matter, and an appendix with tables, &c., of 6 pages, followed by the alphabetical index of the entire work. There are 28 illustrations in Vol. III.

The text of the entire work, as divided between the three volumes, is classified for each volume as follows:—
VOL. I. (i.), Classification of oils, fats, and waxes—Their physical and chemical properties. (ii.), Saponification of fats and waxes. (iii.), Their constituents. (iv.), Preparation of the fatty matter for examination—Preliminary tests. (v.), Physical methods of examining oils, fats, and waxes. (vi.), Chemical methods of examination—Quantitative tests. (vii.), Chemical methods—Qualitative tests. (viii.), Examination of mixed fatty acids. (ix.), Examination of unsaponifiable matter. (x.), Detection and quantitative determination of rosin. (xi.), Application of foregoing methods to the systematic examination of oils, fats, and waxes. (xii.), Examination by strictly scientific methods. **VOL. II.** (xiii.), Commercial preparation of the raw materials used in the industries of the oils, fats, and waxes. (xiv.), Technology of the natural oils, fats, and waxes: Methods of preparing, refining, and examining them, and detecting adulterations. A. Oils and fats—Glycerides. (a), Liquid fats, or oils. (b), Solid fats. B. Waxes. (a), Liquid waxes. (b), Solid waxes. **VOL. III.** (xv.), Technology of manufactured oils, fats, and waxes. Technical and commercial examination of the products of the oil, fat, and wax industries. A. Industries having for their object the refining of oils and fats, and their application to commercial uses. B. Industries in which the glycerides undergo a chemical change, but are not saponified. C. Industries based on the saponification of oils and fats. (a), Candle industry. (b), Fatty acid industry. (c), Soap manufacture. (d), Glycerin manufacture. D. Technology of waxes (candles, polishes, and emulsions). (xvi.), Technology of waste oils, fats, and waxes, and the commercial products derived therefrom. I. Waste oils and fats. A. Fats from refining vegetable oils and fats. B. Waste animal fats. C. Mixed waste greases. II. Waste waxes.

THIRD REPORT OF THE WELLCOME RESEARCH LABORATORIES AT THE GORDON MEMORIAL COLLEGE, KHARTOUM. ANDREW BALFOUR, M.D., B.Sc., F.R.C.P., Director, Medical Officer of Health, Khartoum, &c. Baillière, Tindal and Cox, 8, Henrietta Street, Covent Garden, London. 1908. Price 21s. net.

LARGE quarto volume, containing 477 pages of subject matter, including 27 pages of index, and illustrated by 28 coloured plates, 51 reproductions of black and white drawings, 263 reproductions of photographs, and 19 maps and plans. The subject matter is classified as follows:—
I. INTRODUCTION. **II. TRYPANOSOMIASIS IN THE ANGLO-EGYPTIAN SUDAN.** By R. G. Archibald. **III. KALA-AZAR IN THE ANGLO-EGYPTIAN SUDAN.** By S. Lyle Cummins. Observations on Kala-azar in Kassala Province. By L. Bousfield. **IV. REPORT OF TRAVELLING PATHOLOGIST AND PROTOZOOLOGIST.** By C. M. Wenyon. Some interesting reptiles collected on the Upper Nile. Poisonous snakes of the Anglo-Egyptian Sudan, etc. By R. T. Leiper. **V. REPORT ON ECONOMIC ENTOMOLOGY.** New mosquitoes from the Sudan. By H. H. King and F. V. Theobald. **VI. THE HEALING ART AS PRACTISED BY THE DERVISHES.** By Hassan Effendi Zeki. **VII. REPORT ON THE PHYSICAL CHARACTERS OF SOME NILOTIC NEGROID TRIBES.** By D. Waterston. **VIII. NOTES ON ETHNOGRAPHICAL SPECIMENS COLLECTED BY DR. A. MAC TIER PIRRIE.** **IX. REPORT ON THE CHEMICAL SECTION.** By William Beam. (i.), Special research on gum arabic. (ii.), Chemical composition of Nile waters, etc. (iii.), Poisonous well waters. (iv.), Limestones and limes. (v.), Gypsum deposits, Red Sea province. (vi.), Detection of well pollution by means of fluorescein. (vii.), Chemical composition of some Sudan grains. (viii.), Analyses of oil seeds, earthnuts, safflower, cotton seeds, castor oil seeds, sesame, sesame-cake. (ix.), Some Sudan fats and oils. Heglig fruit. Shea butter. Zawa oil. Ben oil. (x.), Sudan gums. Hashab gum. Tapping for exuding gums. Origin of gum. Conditions affecting its production, etc. Analyses of soils from gum districts. Talh gum. Gum of *Acacia arabica*. Kuk gum. Gums from *Acacia suma* and *Odina fruticosa*. Sabakh gum. Tartar and Wa gums, etc. **X. NOTES ON THE CHEMISTRY OF SUDAN GUMS.** By E. S. Edie. (i.), Pentoses in gums. (ii.), Changes in viscosity.

(iii.), Sugar in gums. (iv.), Optical activity of gums. (v.), Their molecular change. (vi.), Bacterial origin. (vii.), Gum bacilli. (viii.), Gum and beetles. (ix.), Bacterium found in Hashab gum.

LABORATORY MANUAL OF DYEING AND TEXTILE CHEMISTRY. By J. MERRITT MATTHEWS, Ph.D. John Wiley and Sons, New York, U.S.A. 1909. Price \$3.50. Chapman and Hall, Ltd., London. Price 15s.

Svo volume, containing 349 pages of subject matter, and an alphabetical index. Pages 325 to 349 are devoted to an appendix, chiefly containing tables, technical calculations, etc. The subject matter is classified and grouped as follows:—**I.** Chemical study of the fibres. **II.** Scouring textile fibres. **III.** and **IV.** Bleaching of wool and cotton. **V.** Classification of dyestuffs. **VI.** Application of acid dyestuffs. **VII.** Testing the fastness of colours. **VIII.** Application of basic dyestuffs to wool, silk, and cotton. **IX.** Representative basic dyestuffs. **X.** Application of substantive dyestuffs to cotton, wool, and silk. **XI.** Application of mordant dyestuffs to wool. **XII.** Developed dyestuffs on cotton and silk. **XIII.** Sulphur dyestuffs on cotton. **XIV.** Use of logwood in dyeing. **XV.** The minor natural dyestuffs. **XVI.** Mineral dyestuffs. **XVII.** Vat dyes. **XVIII.** Testing dyestuffs, and their reactions. **XIX.** Miscellaneous dyeing tests. **XX.** Testing the fastness of colours. **XXI.** Analysis of textile fabrics.

TRAITE COMPLET D'ANALYSE CHIMIQUE APPLIQUEE AUX ESSAIS INDUSTRIELS. Par J. POST et B. NEUMANN. Avec la collaboration de nombreux chimistes et Spécialistes. Deuxième édition française entièrement refondue. Traduite d'après la troisième édition allemande et augmentée de nombreuses additions. Par le Dr. L. GAUTIER. Tome premier. Troisième Fascicule. Librairie Scientifique A. Hermann et Fils, rue de la Sorbonne, 6, Paris. 1909. Price 8.50 fres.

Svo volume, containing 860 pages of subject matter, and 45 illustrations. Forming part iii. of the entire work, the whole of this volume is devoted to Chapter IX., which treats of the following metals, their ores, extraction, details as to sampling, analysis, etc. A. Iron. B. Metals other than iron, and comprising: (i.), Copper. (ii.), Lead. (iii.), Silver. (iv.), Gold. (v.), Zinc. (vi.), Cadmium. (vii.), Nickel and cobalt, and alloys of nickel. (viii.), Tin and alloys of tin. (ix.), Bismuth and its alloys, etc. (x.), Antimony and its alloys. (xi.), Arsenic. (xii.), Mercury and amalgams. (xiii.), Aluminium and alloys (xiv.), Platinum. (xv.), Chromium. (xvi.), Tungsten. (xvii.), Uranium. (xviii.), Vanadium. (xix.), Molybdenum.

PATENTS, DESIGNS AND TRADE MARKS. TWENTY-SIXTH REPORT OF THE COMPTROLLER-GENERAL. 98. Price 2½d.

This report deals with the work of the Patent Office during the year 1908. The number of applications for patents and for registration of designs and trade marks during that year, as compared with the two preceding years, is shown by the following table:—

	1906.	1907.	1908.
Patents—			
Applications	30,030	28,915	28,598
Specifications—			
Provisional	21,025	19,568	19,495
Complete	18,243	18,829	17,746
Sealed	14,707	16,272	16,284
Designs—			
Applications	22,001	24,928	24,907
Registered	21,212	24,039	24,389
Trade Marks—			
Applications	11,414	10,796	10,645
Registered	4,731	6,255	5,965

EAST INDIA (TRADE). TABLES RELATING TO THE TRADE OF BRITISH INDIA WITH BRITISH POSSESSIONS AND FOREIGN COUNTRIES, 1903-4 TO 1907-8. [Cd. 4595.] Price 1s. 1d.

ORDER IN COUNCIL MAKING REGULATIONS UNDER SECT. 2 OF THE POISONS AND PHARMACY ACT, 1908, AS TO THE SALE OF CERTAIN POISONOUS SUBSTANCES FOR AGRICULTURAL AND HORTICULTURAL PURPOSES. Statutory Rules and Orders, 1909, No. 345. Price 1d. (See this J., April 15, 1909, p. 382.)

Patent List.

Where a complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of Application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

8714. Coplans. Centrifugal separator for filtering liquids. April 13.
 8841. Cowper-Coles. Furnaces. April 14.
 8943. Wedge. Furnaces. [U.S. Appl. April 16, 1908.]* April 15.
 8958. Moscicki. Bringing liquids into intimate contact with gases or vapours. [Swiss Appl. June 1, 1908.]* April 15.
 9072. Porter. Dehydrating apparatus.* April 16.
 9230. Jeffcock and Yardley. Separator for treating gaseous or liquid bodies. April 19.
 9493. Johnson. Apparatus for screening, cleaning, and separating materials with different specific gravities. April 21.
 9672. Mercer. Washing or mixing apparatus. April 23.
 9691. Lymn. Process for dehydrating peat. April 23.
 9698. Leaver, and Brittany China Clay Co. *See under VIII.*

COMPLETE SPECIFICATIONS ACCEPTED.

- 7841 (1908). Churchill. Classifiers for materials of different specific gravities. April 21.
 8821 (1908). Diederichs. *See under V.*
 10,442 (1908). Burstall. *See under II.*
 10,854 (1908). Schmatolla. Gas-fired shaft furnaces. April 21.
 14,693 (1908). Black, Lennox, and Lennox. Apparatus for cleaning or washing smoke and for inducing draught. April 21.
 4684 (1909). Seck. Separating and sorting materials. April 28.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

8914. Fabry. Extraction of sulphuretted hydrogen from the gases evolved by coal distillation. April 15.
 8920. Fabry. Horizontal coke ovens.* April 15.
 8940. Hill and Westwood. Apparatus for making a combustible heating and illuminating gas. April 15.
 8968. De St. Laurent, and Pollux Synd., Ltd. Manufacture of incandescent gas mantles. April 15.
 8969. De St. Laurent, and Pollux Synd., Ltd. Production of light. April 15.
 9076. Lewis. Arc lamp electrodes. April 16.
 9339. Cliff and Williamson. Manufacture of gas retorts. April 20.
 9405. Baglin. Coke ovens. April 21.
 9445. Soc. Anon. d'Ongrée Marilhaye, and Eloy. Coke ovens or furnaces.* April 21.
 9798. Menz. Process for compressing coal gas. [Swiss Appl. April 25, 1908.]* April 24.

COMPLETE SPECIFICATIONS ACCEPTED.

- 8524 (1908). Botley and Cutler. Gas generating plants. April 28.
 10,442 (1908). Burstall. Apparatus for extracting tar, dust, etc., from gases. April 21.

- 14,292 (1908). Fielding. Gas producer. April 21.
 14,604 (1908). Bolz. Gas generating furnace. April 21.
 16,614 (1908). Lake (International Gas Development Co.). Process of making gas. April 21.

IV.—COLOURING MATTERS AND DYESTUFFS.

APPLICATIONS.

8938. Newton (Bayer und Co.). Manufacture of trisazo dyestuffs. April 15.
 8939. Newton (Bayer und Co.). Manufacture of azo dyestuffs. April 15.
 9219. Newton (Bayer und Co.). Manufacture of vat dyes of the anthracene series. April 19.
 9220. Newton (Bayer und Co.). Manufacture of azo dyestuffs and process of developing them on the fibre. April 19.
 9689. Ransford (Cassella und Co.). Derivatives of carbazol and dyestuffs formed therefrom. April 23.

COMPLETE SPECIFICATIONS ACCEPTED.

- 8531 (1908). Imray (Soc. Chem. Ind. in Basle). Manufacture of vat dyestuffs. April 21.
 2918 (1909). Haas. Derivatives of carbazol and dyestuffs formed therefrom. April 21.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

APPLICATIONS.

8744. Alsop and Sibson. Circulating dyeing machine.* April 13.
 8829. Fox. Washing inflammable fabrics. April 14.
 9220. Newton (Bayer und Co.). *See under IV.*
 9307. Regordosa and Regordosa. Continuous dyeing of skeins.* April 20.

COMPLETE SPECIFICATIONS ACCEPTED.

- 7972 (1908). Hübner, and Riley and Co. Waterproof and lustrous cloth or other fabric and its production. April 21.
 8620 (1908). Ashton, and Calico Printers' Assoc. Printing textile fabrics. April 21.
 8821 (1908). Diederichs. Apparatus for treating textiles and for mixing chemicals, etc., with liquids. April 28.
 13,790 (1908). Imray (Meister, Lucius, und Brünig). Manufacture of fatty acid compounds with aldehydes and ketones, and their application in colour printing. April 21.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

8992. Bass. *See under XX.*
 9132. Humphrey, and Brimsdown Lead Co. Apparatus for making litharge and other metallic oxides. April 17.
 9145. Cie. Indus. des Alcools de l'Ardèche. Recovery of sulphurous acid from solutions. [Fr. Appl. June 18, 1908.]* April 17.
 9394. Schlossberg. Manufacture of acid- and fire-proof bodies consisting of pure silicic anhydride.* April 20.
 9618. Ashcroft. Concentration and evaporation of caustic alkali solutions.* April 22.

COMPLETE SPECIFICATIONS ACCEPTED.

- 19,656 (1908). Schulthess. Method and apparatus for slaking lime. April 28.
 21,959 (1908). Moscicki. Production of oxides of nitrogen by means of a rotary flame. April 21.
 21,823 (1908). Steynis. Apparatus and process for producing ozone. April 28.

VIII.—GLASS, POTTERY, AND ENAMELS.

APPLICATIONS.

8974. Thomson. Manufacture of glass from cheap material. April 15.

9698. Leaver, and Brittany China Clay Co. Apparatus for separating particles of different specific gravity, particularly for treating china clay. April 23.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

8754. Lockwood. Manufacture of artificial stone. April 13.

9207. Goddard. Concrete. April 19.

9229. Landgraf. Treatment of cement, ores, etc., in the rotary furnace.* April 19.

9381. Haddan (Meramec Portland Cement and Material Co.). Waterproof Portland cement and process for making same.* April 20.

COMPLETE SPECIFICATION ACCEPTED.

8307 (1908). Eggenhöfner and Sbertoli. Magnesia cements. April 21.

X.—METALS AND METALLURGY.

APPLICATIONS.

8773. Talbot. Utilising iron oxides and certain slags in the manufacture of iron and steel. April 13.

8778. Schoop. Welding objects of aluminium or aluminium alloys. [Addition to No. 24,283 of 1907.]* April 13.

8781. British Thomson-Houston Co. (General Electric Co.). Manufacture of rods or filaments of refractory metal. April 13.

8834. Wales. Alloys of iron, particularly for armour plates.* April 14.

8835. Wales. Treatment of armour plates, etc.* April 14.

8842. Simpson and Oviatt. Direct production of steel from the ore. [Comprised in No. 5802, March 10, 1909.] April 14.

8970. De St. Laurent, and Pollux Synd., Ltd. Alloys. April 15.

9091. Kelsey and others. Treating zinc for use in solder, etc. April 17.

9108. Peyton. Hardening steel or other metals. April 17.

9158. Weeks. Apparatus for calcining, desulphurising, agglomerating, and sintering ores, etc. [U.S. Appl. April 18, 1908.]* April 17.

9163. Simpson and Oviatt. Direct production of iron and steel from the ore. April 17.

9229. Landgraf. *See under IX.*

9286. Kelsey and others. Soldering aluminium and other metals. April 20.

9287. Kelsey and others. Alloy suitable for casting. April 20.

9300. Martin. Separating complex ores or their products. April 20.

9397. Levy. Extracting tin, arsenic, etc., from hard-head, tin smelters' products, etc. April 21.

9508. Greene. Refining metals and alloys.* April 21.

9614 and 9615. Sulman, and Metals Extraction Corporation. Treatment of ores and mineral substances. April 22.

COMPLETE SPECIFICATIONS ACCEPTED.

5244 (1908). Clinch-Jones. Annealing metals. April 21.

12,258 (1908). Hugot. *See under XI.*

12,825 (1908). Down and Morgan. Rotary roasting furnace. April 21.

18,680 (1908). Lessing. Briquetting ore with blast-furnace slag. April 28.

19,163 (1908). Haddan (Eccleston). Ore concentrators. April 28.

24,244 (1908). Schneider et Cie. Treatment of steels. April 28.

24,685 (1908). Potter. Working manganese steel. April 21.

28,081 (1908). Kurz. Manufacture of leaf metal, particularly leaf gold. April 28.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

8734. Backus. Electroplating apparatus. [U.S. Appl. April 13, 1908.]* April 13.

8863. Walton. Manufacture of a composition for electric insulating. April 14.

9796. Bradley and Williams. Electrolytic cells. April 24.

COMPLETE SPECIFICATIONS ACCEPTED.

5214 (1908). Jungner. Galvanic gas batteries. April 21.

5223 (1908). Jungner. Galvanic gas elements. April 21.

12,258 (1908). Hugot. Electric furnaces for the manufacture of steel. April 21.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

APPLICATIONS.

8768. Finlay. Manufacture of wax for candles, etc.* April 13.

8982. Welter. Making soaps containing solvents of fat.* April 15.

9441. Nauton frères et de Marsac, and Tesse. Saponaceous neutral paste. [Fr. Appl., March 10, 1909.]* April 21.

9590. Bloxam (Jacobi). Apparatus for cooling soap. April 22.

9802. Brown. Manufacture of soap. April 24.

COMPLETE SPECIFICATION ACCEPTED.

9096 (1908). Pritchard. Apparatus for making soap. April 28.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(A.)—PIGMENTS, PAINTS.

APPLICATIONS.

8686. Profes. Paints.* April 13.

8967. Luciani and Battesti. Apparatus for the manufacture of artificial ultramarine. [Fr. Appl., April 15, 1908.]* April 15.

COMPLETE SPECIFICATIONS ACCEPTED.

15,921 (1908). Newton (Bayer und Co.). Preservative compositions. April 28.

18,616 (1908). Johnson (Badische Anilin und Soda Fabrik). Manufacture of pigments or lakes. April 21.

(B.)—RESINS, VARNISHES.

APPLICATION.

8882. Hollinger. Production of linoleum imitating wood.* April 14.

(C.)—INDIA-RUBBER.

APPLICATIONS.

9284. Markus. Utilisation of waste rubber. April 20.

9794. Blaisdell. Manufacture of a unified mass of strained rubber. April 24.

XIV.—TANNING, LEATHER, GLUE, SIZE, Etc.

APPLICATIONS.

8960. Johnson (Chem. Fabr. Elektro). Manufacture of compositions for use in dressing leather. April 15.

9383. Buffum and Carter. Waterproof leather board. [Addition to and comprised in No. 28,219, Dec. 28, 1908.]* April 20.

XVI.—SUGAR, STARCH, GUM, Etc.

APPLICATIONS.

9148. Grière. Direct conversion of sugar syrups into crystallised sugar. [Belg. Appl., April 25, 1908.]* April 17.

9370. Paira, and Administration der Minen von Buchsweiler. Production of soluble starch.* April 20.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

9157. Anker. Storage and fermentation vessels. April 17.

COMPLETE SPECIFICATION ACCEPTED.

1269 (1909). Melhuish. Treatment of malt liquors. April 21.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; AND DISINFECTANTS.

(A.)—FOODS.

APPLICATIONS.

9440. Ikeda and Suzuki. Preparation of a nutritive and flavouring substance.* April 21.

9537. Epstein. Treatment of cocoa and chocolate. April 22.

9682. Johnson (Chem. Fabr. vorm. Goldenberg, Geronmont, und Co.). Manufacture of baking powders. April 23.

9716. Little. Treatment of flour. April 23.

COMPLETE SPECIFICATIONS ACCEPTED.

5155 (1908). Hogarth. Treating and conditioning cereals and their products and other alimentary substances. April 28.

9691 (1908). Beck and Angermüller. Treating grain preparatory to and in milling. April 21.

11,653 (1908). Schwartz and Schwartz. Manufacture of aerated beverages. April 28.

19,455 (1908). Rousseau. Cream preparation. April 21.

(B.)—SANITATION; WATER PURIFICATION.

COMPLETE SPECIFICATIONS ACCEPTED.

15,570 (1908). Storey. Treatment of vapours from refuse destructors, etc. April 21.

27,272 (1908). Marks (Oliver-Roche Co.). Water purifying apparatus. April 21.

XIX.—PAPER, PASTEBOARD, Etc.

APPLICATIONS.

8945. Lederer. Manufacture of sheets or objects from cellulose acetate.* April 15.

9340. Pasmore and Gilroy. Manufacture of adhesive art or coated papers. April 20.

COMPLETE SPECIFICATION ACCEPTED.

28,538 (1908). Ratignier, and Pervillac et Cie. Manufacture of pellicles or films. April 28.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

APPLICATIONS.

8992. Bass. Mixing machine for manufacturing citrate of lime. April 16.

9128. Smythe and Smythe. Prophylactic kolloid. April 17.

COMPLETE SPECIFICATIONS ACCEPTED.

13,790 (1908). Imray (Meister, Lucius, und Brüning). *Silinder V.*

22,132 (1908). Justice (Boehringer Sohn). Salts of sulpho acids of guaiacol carbonate. April 21.

XXI.—EXPLOSIVES, MATCHES, Etc.

APPLICATION.

8962. Pay and Goodricke. Manufacture of explosives. April 15.

COMPLETE SPECIFICATION ACCEPTED.

20,214 (1908). Palmer. Explosives. April 28.

XXII.—GENERAL ANALYTICAL CHEMISTRY.

APPLICATIONS.

9368. Barron (Moir). Colour screens for detecting potassium. April 20.

9518. Brenot. Apparatus for analysing gaseous mixtures and recording the result. [Fr. Appl., April 22, 1908.]* April 21.

DR. JAMES T. CONROY IN THE CHAIR.

I. THE COMPOSITION OF SHEA BUTTER.

BY JAS. E. SOUTHCORBE, M.Sc.

On the Continent of Europe recently considerable attention has been directed to the utilisation of shea butter both as a foodstuff and as a raw material for soap and candle making, the high titre of the fatty acids rendering it peculiarly valuable in the latter industry, while it has been found possible to use it with considerable success for soap-making when mixed with from 10 to 30 per cent. of other oils.

While these technical investigations have been diligently pursued, the chemistry of the fat appears to have received but little attention, and so far as the author is aware, no attempt has been made to elucidate its composition since the publication of Stohmann,* who gives for the composition of the fat seven parts of tristearin to three of triolein, but it has been pointed out by Lewkowitsch that these figures are not in accordance with the iodine value of the fat determined by several investigators.

The writer, having recently had several samples of the nuts and fat for examination, has made a study of the composition of the fat.

Two varieties of *Bassia Parkii* are known, the fruit of which yields fats of slightly different properties, viz., shea nuts and kariti nuts. The fats from these different varieties are frequently spoken of indifferently as shea butter, but the constants of the respective fats present marked differences.

Analyses of samples of kariti and shea nuts from different sources give the following figures:—

Source.	Yield of fat.	Melting point.	Saponification value.	Iodine value.
	Per cent.	° C.		
Kariti.. Soudan	35.0	27	177.1	66.0
" .. —	32.7	25	175.3	67.1
Shea .. Bida, Nigeria	53.6	30	183.4	56.2
" .. S. Nigeria	49.8	27-28	173.9	54.8
" .. —	51.3	30	177.5	57.5

In the author's experience the kariti nut always yields considerably less fat of lower melting point and higher iodine value than the shea nut. The sample used for this investigation was native prepared and contained 0.6 per cent. of moisture and 2 per cent. of foreign matter (sand, fibre, &c.).

The following table gives the analytical data for the sample:—

Sp. gr. 98-99° C.	Melting point.	Solidifying point.	Acid value.	Saponification value.	Iodine value.	Hegner value.	Reichert-Meissl value.
0.861	29° C.	20-21° C.	26.17	178.7	57.6	93.8	1.15

Attempts were made, in the first instance, to separate the glycerides by fractional crystallisation and a quantity of tristearin was isolated in a fairly pure condition, but no satisfactory quantitative separation could be effected. Accordingly the purified fat was saponified, the resultant soaps dried and treated with petroleum ether, when 3.8

per cent. of a fragrant resinous unsaponifiable matter was extracted. The sodium soaps were decomposed with lead acetate, and the resulting lead salts treated with ether by the process of Ruggieri and Tortelli. The soluble lead salts yielded liquid acids absorbing 90.6 per cent. of iodine, and on oxidation with alkaline permanganate were converted wholly into dihydroxystearic acid, no sativic acid being detected. The solid acids melted at 52-57° C., absorbed 3.2 per cent. of iodine, and had a molecular weight of 275. 25 grms. were dissolved in the minimum quantity of alcohol at 0° C. and fractionally precipitated with magnesium acetate.

The free acids from the magnesium soaps gave the following figures:—

Fraction.	Weight.	Melting point.	Mol. weight.
	Grms.	° C.	
1	5.4	68-68.5	287
2	6.1	65-67	280
3	7.0	59-60	270

The residue fractionally crystallised from alcohol yielded a further quantity of stearic and lastly a small amount of lauric acid (m. pt., 43-44° C.; mol. wt., 210).

A determination of stearic acid in a separate portion of the solid acids gave the value 90.5, and as no palmitic acid was detected the solid acids must consist of about 4 to 5 per cent. of lauric acid and 90.5 per cent. of stearic acid contaminated with oleic acid.

From the foregoing it would appear that the insoluble acids in shea butter are oleic, stearic, and lauric, with a possible small quantity of linolic, and accordingly from the iodine value of the mixed fatty acids we are able to calculate the approximate percentage composition, viz.:—Oleic acid, 60 per cent.; stearic acid, 30-35 per cent.; lauric acid, 3-4 per cent.

Several samples of the fat examined were distinctly rancid, possessing a disagreeable odour and taste which was not completely removed by washing with alkali. Shea butter as imported into this country would appear to be particularly liable to oxidation in this way, since the crude methods of extracting the fat practised by the natives leaves a considerable quantity of nitrogenous matter in the bulk. It is interesting in this connection to note that there is a perceptible rise in the percentage of volatile fatty acids in butter which has been stored for some time.

Samples of crude and purified butter were allowed to stand for some months in the laboratory in open vessels. The following table shows the rise in Reichert-Meissl value:—

	Crude fat.	Purified fat.
Fresh	1.10	0.75
Two months later	1.56	0.90
Four months later	1.8	0.90

The author begs to thank the committee of the Institute of Commercial Research in the Tropics, and Prof. B. Moore, of the Bio-Chemical Department, Liverpool University, for kindly placing facilities for this research at his disposal.

II. ANALYSIS OF THE OIL FROM THE SEEDS OF *SYMPHONIA GLOBULIFERA*.

BY J. E. SOUTHCORBE, M.Sc.

The seeds are obtainable in considerable quantity in South America. They are ovoid in shape, about 1-2 in. long and $\frac{3}{4}$ -1 in. broad. The interior of the seed is mottled yellowish white when fresh, but darkens on long standing. On extraction with petroleum ether the seeds

* See Muspratt's Chemistry, 4th Edition, Vol. 3, 574.

yield a dark reddish-coloured fat possessing the following characters:—

Mixed fatty acids.

Sp. gr. 99-100 °C.	Melting point.	Solidifying point.	Iodine value.	Unsapo- nifiable matter.
0.891	48-50 °C.	46 °C.	64.8	Per cent. 1.1

DISCUSSION.

In reply to some questions, Mr. SOUTHOMBRE said the natives extracted the fat by macerating the nuts with hot water and skimming off the fat from the surface, in which process it naturally became contaminated with leaves, pulp, etc. He had not been able to make any exhaustive examination of the unsaponifiable matter, but it was a whitish resinous mass possessing a fragrant odour resembling vanilla, and yielded a small quantity of volatile oil on distillation. It might possibly be interesting to examine it further, but so far as the utilisation of the fat as a foodstuff was concerned, the presence of the unsaponifiable matter would not be objectionable in the least.

London Section.

Meeting held at Burlington House on Monday, March 1st, 1909.

DR. J. LEWKOWITSCH IN THE CHAIR.

SOME REQUIREMENTS OF A COLOUR STANDARD.

BY JOSEPH W. LOVIBOND.

Colour standards must be available for use under ordinary daylight conditions, and for determining the colour of liquids, solids, or gases they may be either fixed points or scales, but scales have a much wider range of application. The character of the light used in preparation must be defined, both for intensity and composition. The angle of incidence of the light must be defined, and also the distance of the eye from the object of vision, the latter on account of the intensity of the light reflected, the former as causing variations in colour and intensity.

In order to standardise the sensation of colour it must be correlated to a physical colour-constant, for which the following have been suggested, and used with more or less success:—The solar spectrum, the spectrum of the arc light, the colours of diffused daylight, pigments, chemical solutions. The solar spectrum naturally suggests itself as a standard, and at first appears to be promising; practical work, however, discloses so many complications that up to the present no satisfactory results have been arrived at. It does not furnish a workable area uniform in colour over its whole surface; the source of light must be intense, and no intense light has yet been found sufficiently constant, either in intensity or in colour-ray composition; spectrum colours are only fully distinguishable in a specially darkened room, whereas everyday work must be carried on in daylight.

The range of spectrum colours is limited in two directions compared to the range of daylight colours, in that it has no representation of mixtures of red and violet which really form one-sixth of the daylight colour cycle, and, secondly, only one combination is possible for any two overlapping monochromes of a given wave length.

The spectra of incandescent vapours may possibly prove to be constant as standards for definite colours, but work up to the present is not very hopeful.

Pigments may ultimately furnish reliable colour standards, and the mechanical difficulties of uniformity in chemical composition, in grinding, in media, and in the manner of presentation, may be overcome, but there remain other complications. Few pigments are sufficiently pure to represent true monochromes, the reds in most cases being tinged with violet or orange; the yellows with orange or green; and the blues with green or violet, the proportions varying with each density.

In all questions of mixing pigmentary standards, corrections are required for variations in the natural colour depth of different pigments, in order to bring them into equivalence. In water colours, for instance, one of the deepest reds (carmine) registers 19 red units; the deepest yellow (demon yellow) only 9 yellow units; and the deepest blue (cobalt) 12 blue units; these numbers are only approximate, as they vary more or less by every maker, and at times in different samples by the same maker.

Comparisons with pigments are not readily made with transparent liquids or gases, and the colours of pigments are not sufficiently stable for a lengthened period.

Chemical solutions are already used as colour standards for specific purposes, but the colour variations are too limited for wide application. They have, however, proved of service for many specific purposes, and in verifying the equivalence of tintometrical colour scales.

The colours developed by the selective absorption of diffused daylight have, up to the present, proved the most reliable as colour standards, but some precautions are required in order to insure constancy in reading.

The use of direct sunlight in colour comparisons is known to lead to confusion, for apart from variations in intensity, there are quality variations at different seasons, and at different times of the day. The colours developed by direct sunlight are also not in accord with those developed by the same light after diffusion.

No artificial light has yet been found sufficiently reliable as a standard light for colour comparisons, being subject to some of the disabilities of direct sunlight, though some applications of a limited character have been obtained by modifying the light of a standard candle, such as the measurement of fog densities, and that of other lights below the intensities of ordinary daylight.

Diffused daylight as an illuminant is free from most, if not all, the disadvantages of direct lights, and has the distinct advantage, that whilst one part of the impinging beam illuminates the object, another part illuminates the colour standards. The work already done leaves but little doubt that, in reading colour sensations for record, constancy is obtainable by observing certain conditions, all of which appear to be within the limits of definition. The principal points to be defined are the intensity of the light, the angle of incidence, and the degree of diffusion.

Among the conditions of observation are:—Variations in light intensity, limitations of angle of light incidence, and of degree of diffusion, and limitations in distance between the eye and the object and in time of observation.

By variations in light intensity, the variations incident to direct lights as such are not meant, but the variations due to the preponderance of white light as a component of a coloured beam. Theoretically, the smallest proportional variation comes within the range of argument, but the discriminating power of the human vision is limited, with the result that there is a considerable range of proportional variations in light values, which appear to be constant to the eye.

In order to define these limitations, measurements were first made of the six water colour pigments, red, orange, yellow, green, blue, and violet, in a diffused daylight of 26 units intensity as reflected from the standard white surface, then with decreasing intensities of the same light, which was regulated through a conical rectangular hopper tapering from 2 feet to 2 inches square. The small end was brought sufficiently close to the object, as to exclude side lights. The wide outer end was fitted with shutters, for reducing the light intensities by limiting the area of aperture.

TABLE A.—*Influence of light variations on constancy of colour readings.*

Light area.	Light intensity.	Red. "Carmine."	Yellow. "Lemon."	Blue. "Cobalt."	Orange. "Chrome."	Green. "Emerald."	Violet. "Fr. Mauve."
Sq. ins.	Units.	Red. Or. Blk.	Yel. Or.	Blue. Vio. Blk.	Or. Red. Light.	Gr. Yel. Light.	Vio. Red.
	26	16.9 + 1.1 —	7.0 —	10.5 + 0.5 + —	6.0 + 3.2 + —	6.6 + — + 0.05	7.2 + 2.8
12	22	16.9 + 1.1 —	7.0 —	10.5 + 0.5 + —	6.0 + 3.2 + 0.05	6.6 + — + 0.2	7.2 + 2.8
10	20	16.9 + 1.1 + —	7.0 —	10.5 + 0.5 + —	6.0 + 3.2 + 0.05	6.6 + — + 0.2	7.2 + 2.8
8	16	16.9 + 1.1 —	7.0 —	10.5 + 0.5 + —	6.0 + 3.0 + 0.05	6.6 + — + 0.2	7.2 + 2.8
6	14	18.95 + 0.50 + 0.46	6.9 + 0.1	10.7 + 0.2 + 0.1	6.2 + 3.0 + —	6.4 + — + 0.05	7.2 + 3.0
4	11	19.1 + 0.4 + 0.5	6.9 + 0.1	11.5 + — + —	6.0 + 3.4 + —	6.4 + 0.2 + 0.05	7.4 + 3.0
2	10	20.2 + 0.3 + 0.5	6.9 + 0.1	11.5 — — —	6.0 + 3.4 + —	6.4 + 0.2 + 0.05	7.4 + 3.0

The results on Table A show the colour readings to be constant until the light intensity is reduced to 16 units by the 8 inch square aperture. These limitations between 26 and 16 units fairly accord with those between 28 and 18 already observed in laboratory practice. After 16 units intensity the readings vary, but at different rates for the several colours, each colour having an idiosyncrasy of its own.

The proportion of incident light reflected to the eye from a flat surface varies with the angle of incidence. This also applies to colour rays developed by selective absorption, but the rate varies for different colours, as shown by the curves in Diagram B. The nature of the

show that the readings were uniform for all the colours between the perpendicular and 40 degrees, after which each had a rate of loss specific to itself down to an angle of 70 degrees when the object passed out of view.

As this is only a preliminary experiment and the first of its kind, it will be unwise to draw definite conclusions, but it may be remarked that the rate of decrease varies for each colour. Green, for instance, after losing 15-hundredths of a degree between the angles of 20 and 40, continues unaltered until it passes out of vision.

By degree of diffusion, is meant sunlight after it has been subject to numberless natural reflections, refractions, dispersions, and absorptions before impinging on a surface

TABLE B.

Colour Measurements of Six Water Colour Paints with Diffused Daylight at different Angles of Incidence.

surface also has an influence in determining the colour proportions of the beam, and, therefore, care was taken that the pigmentary surfaces were of similar smoothness. These facts made it necessary to find the angle limitations which gave uniform readings. Experimental work has already determined that an inclination of 15 degrees of the optical instrument to the objective surface gave constant results, and also that slight variations from this caused no disturbance. In order to define the angle limitations more precisely, the following set of observations were made:—Six water colour pigments were prepared as already described for diffused light, and measured under a diffused light of 26 units, the angle variations being made by altering the inclination of the optical instrument. The results are plotted in curves on Table B. The curves

already screened from the direct rays. It was for a time considered that such a light when taken from the north, or from opposite the sun's meridian, and of a luminous intensity between 18 and 28 units, was constant for colour comparisons. This, whilst generally true, requires qualification, as some substances are sensitive to colour changes within narrower limits than these, especially when in a bright sunlight passing clouds reflect varying proportions of direct rays to the object.

Ten inches is the best average distance between the object and the eye, but the ordinary distance at which the observer holds a book is a factor to be considered.

On continuously viewing a colour, the nature of the sensation excited changes as time goes on: this makes it necessary to establish a time limit for the observation

of colour standards. I find 3 seconds' observation for dark colours and 5 for light colours to be the extreme limits in practice, but I am led to believe that the ideal time varies for the different colours, by finding that continued observation increase the sensibility for all colours, but at widely different rates, being the greatest for red, and the least for yellow.

The standard colours are derived from a white light, in such a condition that it excites no special colour sensation in the vision at any degree of intensity; when in that condition it is composed of the six colour rays, red, orange, yellow, green, blue, and violet in equal proportions, and is termed "Normal white." On any departure from this condition of colour-equivalence, the light becomes abnormal or coloured, the colour being that of the one or two preponderating rays, and the depth of colour being in proportion to their preponderance. To measure a given colour, a beam of normal white light is analysed to correspond to the colour, by means of a set of scales of selective colour absorbents, which are colour-constants by having been co-related to freshly prepared pure chemical solutions; they then comply with the essentials of a scientific scale, in that the divisions are equal, and the unit recoverable.

Besides the curves descriptive of colour measurements under different angles and conditions, the author produced a coloured illustration comparing the solar spectrum with Rood's diffraction spectrum and a circle of graded tints showing the "Tintometer cycle of colour constants."

DISCUSSION.

The CHAIRMAN congratulated Mr. Lovibond upon having found a quantitative expression for colour sensation in his tintometer, an apparatus which had acquired great practical importance. It was now used in the United States as a basis in cotton-seed oil transactions, and was the only apparatus relied upon. It had not yet become the custom in this country to buy cotton-seed oil on the basis of colour, as expressed by units of the tintometer scale, but on the Continent, this oil was already sold by this standard. They were aware that also in other industries the tintometer was largely used.

Mr. JULIAN L. BAKER said Mr. Hulton and himself (this J., 1906, 552) had critically examined the results afforded by the Lovibond tintometer, because in the malting industry it was now customary to buy malt on certain standards, one being the colour of the hot aqueous infusion. They found, as others probably had found, that buyer and seller did not always agree, but they were able to narrow down the differences to the position of the instrument in relation to the source of light, and to lay down fairly well defined conditions under which it would be possible for different observers to obtain approximately the same results. He understood that Mr. Lovibond had further perfected his instrument by devising a standard light; and he was hoping they would have heard something about it.

Mr. GRANT HOOPER asked if the author said that it was necessary to provide an adjustment for focussing in making observations. At the present time the instrument in general use had no such arrangement and the determinations were made at a fixed distance. Had the author made any progress in what might be called a neutral colour? On each occasion when the question had arisen before, it had been pointed out, and he thought generally agreed, that an exact comparison of two different colours which were not of the same brightness could not be made. The practical point to be solved in connection with the use of this instrument therefore seemed to him to be the production of a neutral tint which would permit of the colours being dulled to the same extent so that the comparison could be made under equal intensity of light. This was now done by a combination of glasses, but a single neutral tint glass which, though theoretically it produced no colour, yet did actually diminish the brightness, was desirable. There was undoubtedly a difference in the sensitiveness of the eyes of different persons, and one could not expect that two observers with a different natural appreciation of colour would arrive at precisely the same result. This of course did not imply any defect in the instrument.

Mr. LOVIBOND said that was impossible. He should like Mr. Hooper to describe the position of the laboratory in which the discrepancies he referred to occurred. If one got too far within the laboratory, so that the light became complicated by broken side lights, there was confusion at once, and the vision of individuals would from some unknown cause differ; but given a proper amount of light and the same conditions of observation, he thought his experience was sound. Reliable work could be done with daylight between 16 and 26 units. In his book he said between 18 and 28, as reflected from the standard white surface. The direct daylight used was about 9 units stronger, because about 9 units were lost in the reflection. It was a very poor daylight that was below 16 units, even on a dull winter's day.

Mr. GRANT HOOPER said that Mr. Lovibond's experiments seemed to be a little more fortunate than his own. He had known in the same laboratory and under the same conditions of light, two or three different observers to get slight differences. He wanted to clear the ground as it were, so that those differences though small in amount should be recognised as a margin of error which might be expected and which should be taken into account with the object of avoiding controversy.

With reference to the neutral tint glass, it had to be borne in mind that in comparing the colour of a liquid under the best conditions of light available it was often found that when the colours had been closely matched there was still a difference which bothered one. The two were not equally bright, but by putting in a combination of colours producing a neutral tint an exact comparison became possible. He suggested that something might be done in the way of developing a series of compound glasses giving neutral tint by which the degree of brightness could be brought down to that of the solution with which one had to deal.

Mr. LOVIBOND, in reply, said it was undoubtedly better to focus, but it was sometimes necessary to have it out of focus. For instance, when the surface to be examined was irregular, the colour of the elevations must necessarily vary from the colour of the depressions, in which case it was thrown as little out of focus as possible so as to unite the whole broken colours in one beam. That was a matter of practice; there were two or three ways of doing it: First, he had lenses of different *foci* to drop on the eye piece, but the readiest way was, to close the eyelids a little, and then a match could be made quite easily. The description of neutral tint as a pigment was scarcely a full explanation; neutral tint may rather be described as the difference between two normal white lights of different intensities, and is applicable wherever this difference exists, as well as in pigments of a dull character, it is easily measurable and is represented in the tables by numerals; all such colours were below the colour purity of the standards used. For colours brighter than standards a measurement is effected by the interposition of neutral tint glasses of known absorptive value which reduces the brightness to that of the standards, the unit values of the intercepting glasses are then considered as light units in contradistinction to the black factor of dull colours; for instance, the blue glass standards used are coloured by cobalt which has a spectrum absorptive band in the green, therefore bright greens more frequently require a light factor than other colours; he was not sure that this explanation was truly philosophical, but it was at least practical and definable. With regard to the difference in observers, he found that the people who passed through his laboratory were all normal (except, of course, the colour blind) after training, although some were longer learning than others; he thought that the noticed differences of colour perception between individuals was mainly, if not entirely due to want of colour education, or to physical differences in the conditions of observation. As an instance of the latter, he called to mind the colour matching experiments by means of mixed lights by Sir William Abney in the old days at the Society of Arts which passed the lecture room screen tests; he afterwards had an opportunity of repeating the experiments with the late Professor Hummel at the Yorkshire College. They found no difficulty in matching colours as at the lecture, the difficulty arose on changing

the position of the observer a little to either side, or forward or backward, when the colour no longer matched. If that held good in ordinary daylight observation, it would easily be understood that no two persons would agree exactly; because it was almost impossible that they could view under exactly similar conditions of position and light incidence. It was to overcome this difficulty that the optical instrument was designed. They were dealing with practically a new branch of science; and no quantitative colour work had been done until a colour sensation was correlated with a physical colour constant. Up to that point there was no possibility of precisely defining a colour sensation.

Meeting held at Burlington House on Monday, May 3rd, 1909.

DR. J. LEWKOWITSCH IN THE CHAIR.

THE INDIAN MAGNESITE INDUSTRY.

BY H. H. DAINS, F.I.C.

The first idea of the possibility of starting a magnesite industry in India seems to have originated with Dr. Macleod, who experimented with the Salem magnesite and reported on it to the Government of India in 1826. He suggested the use of it as a substitute for imported cement. It is only within recent years, however, that work on anything like a large scale has been carried on.

The principal deposits lie in the "Chalk Hills," two miles from the town of Salem in the Madras Presidency, 200 miles west of Madras, and an equal distance from the port of Beypore on the West Coast. These ports are connected by the Madras Railway, which passes within a mile of the deposits. The magnesite covers a superficial area of about 2,000 acres and occurs in abundant irregular veins of unknown depth, which exceeds 60 ft. The veins intersect an ultrabasic intrusion of eruptive rock called dunite, after its prototype, native at the Dun Mountain, New Zealand.

This rock, which is ultra-basic on account of the absence of felspar and quartz, has undergone a series of remarkable mineral changes owing to the non-resistance of the unstable olivine to metamorphic influences. The change resulting in the formation of magnesite may be expressed somewhat as follows:—

*Dunite		
	Olivine	Chromite
(containing a little iron)		
	Serpentine	
(A number of varieties, e.g., Massive, Retinalite, and Picrolite)		
	Magnesite.	Chalcedony. Silica, etc.

Serpentine is found widely disseminated throughout the deposits associated with the magnesite, but for the most part in small quantities. The magnesite varies slightly in appearance and composition. The outcrops are of a greyish colour and intensely hard. Under the surface it becomes softer the greater the depth at which it is found, and in some cases where water has had access to the veins it can be almost dug out with a spade, and crumbles readily in the hand.

Generally the magnesite is almost perfectly white. It has a sp. gr. of 3.0 to 3.06, and a hardness of about 5.

The average mineral is of excellent quality, being exceptionally low in lime, silica, iron oxide, and alumina. It contains about 96—97 per cent. of magnesium carbonate, but picked specimens have given as much as 99 per cent.

Other sources of supply where magnesite is worked are Euboea in Greece, Styria, California, Canada, South Africa and Macedonia. The Greek magnesite most nearly approaches the Indian variety.

Magnesite in the raw state is used chiefly for the manufacture of carbon dioxide. In the United States of America, magnesite is very largely used for this purpose, the gas being obtained by calcination in retorts. The residue is sold to makers of refractory bricks by whom it is made up into bricks for basic furnaces. In some works the carbon dioxide is evolved by the action of sulphuric acid.

Calcined magnesite is of great commercial value. The

calcined material may be classed according to the temperature at which the calcination takes place, as: (a) lightly calcined, or caustic magnesia; (b) dead burnt, sintered, or shrunk magnesia. The caustic magnesia is obtained by calcining at a temperature of 800° C., and the process is best carried out in a gas-fired kiln. It is largely used for Sorel or oxychloride cements, fire-proof partitions, plaster, artificial stone, steam packing, flooring, grindstones, millstones, emery and polishing wheels, etc. At Salem the caustic magnesia was first obtained by calcination in ordinary lime kilns. These, however, gave an inferior product owing to the contamination with fuel ash. A regenerative gas-fired kiln has now been erected and is working satisfactorily, the material produced being a great improvement, both as regards colour and quality, on the old bottle-kiln material:—

Indian caustic magnesia.

	From old kilns.		Gas-fired kiln.		
	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.
Loss on ignition	4.62	4.82	5.76	1.82	2.31
Silica	1.64	1.72	1.36	1.13	0.54
Insoluble residue	—	—	—	1.13	0.54
Oxide of iron and alumina	1.02	0.94	0.74	0.63	0.44
Lime	1.53	2.43	2.25	1.06	1.03
Magnesia	91.03	90.18	90.28	95.80	96.10
	99.84	100.09	100.39	100.44	100.42

The standard quality stipulated for by continental consumers at the Leipzig meeting, December, 1908, is 85—90 per cent. magnesia with the lime not exceeding 4 per cent., conditions which the Indian magnesia easily fulfils.

Sorel cement is formed by mixing the caustic magnesia with a solution of magnesium chloride of sp. gr. 1.162 to 1.263. This cement is very hard, white, and of great durability, and will carry up to 20 parts of sand for one of magnesia. When used with sawdust as an aggregate it makes a practically noiseless and dustless flooring.

Dead-burnt or shrunk magnesia is obtained by calcining at a temperature of not less than 1700° C. At Salem the calcination is done in a Schneider kiln, but it would be preferable to calcine in a gas-fired kiln to avoid contamination with the ash from the fuel. The product thus obtained is very basic, and has a sp. gr. of 3.5. It is free from carbon dioxide, and has practically no tendency to absorb water.

Indian dead-burnt.

	Schneider kiln.		Gas-fired kiln.
	Per cent.	Per cent.	Per cent.
Silica	4.92	5.59	4.38
Ferric oxide	2.74	2.20	1.02
Alumina	1.92	1.67	1.04
Lime	89.53	89.83	93.12
Magnesia	0.39	0.34	0.34
Loss on ignition	—	—	—
	99.50	99.63	100.00

The principal uses of dead-burnt magnesia are as a refractory lining for open-hearth furnaces and converters in the steel industry, for rotary kiln linings in Portland cement manufacture, for furnace hearths, crucibles, cupels, and refractory bricks. The most refractory dead-burnt magnesia is obtained from magnesite containing little or no lime, silica, oxide of iron, and alumina. The Indian magnesite is exceptionally low in these deleterious compounds.

The presence of much lime in magnesite bricks used for high temperatures causes them to disintegrate, and in basic steel furnaces is said to cause the phosphorus to pass into the hearth instead of the slag, the hearth thereby becoming "rotten." Silica, oxide of iron, and alumina are objectionable because they lower the fusing point.

For dead-burnt magnesia a high temperature of

calcination is required as it is absolutely necessary not only to drive off all the carbon dioxide but to thoroughly shrink the resulting magnesia.

Styrian magnesite is largely used for making refractory bricks, but it contains a high percentage of iron oxide.

Styrian dead-burnt.

	Per cent.	Per cent.
Silica	2.20	3.40
Iron oxide	7.70	7.60
Alumina	1.02	4.05
Lime	4.92	84.29
Magnesia	83.92	99.34
	99.76	99.34

Dead-burnt magnesia has replaced dolomite to a great extent in basic furnaces because it is not hygroscopic and can therefore be kept any length of time without deterioration whereas owing to the high percentage of caustic lime in dolomite this material rapidly deteriorates on exposure. Dolomite is useless after being once used and whereas 550 to 1100 lb. on an average of this calcined material is required for repairs after each open hearth heat, with dead-burnt magnesite only 110 to 220 lb. is required.

Experiments have been carried out in the calcination of the Indian magnesite on a large scale in electric furnaces. In this process the magnesia becomes partly fused, and the resulting product is a crystalline mass of thoroughly shrunk material having a specific gravity of 3.58. The crystals have the same well defined cubic cleavage as periclase—the natural crystalline magnesium oxide. This crystalline material has been used with much success as a wash and a lining in electric furnaces.

Bricks are usually made in this country by grinding the dead-burnt magnesite in an edge-runner mill, mixing with water in sufficient quantity to make a plastic mass, and moulding in an ordinary hand brick press. The bricks after careful drying are burnt in a high temperature kiln. Another process, however, is to grind the crude material and then add water to enable the crude to be moulded into bricks. These are then burnt and the resulting bricks, which are about half the volume of the original bricks, are then ground again, mixed with water, moulded and burnt. The usual practice on the continent is to mix the ground calcined material with tar, mould, place in a hydraulic press, and after drying burn in a gas-fired kiln. The volatile portions of the tar escape, leaving in the interstices a carbonaceous residue which binds the whole together.

Indian magnesite bricks (sp. gr., 3.58) (Westmoreland).

	(1).	(2).
	Per cent.	Per cent.
Silica	2.60	3.15
Ferric oxide	1.91	0.53
Alumina	1.53	0.23
Lime	93.94	94.28
Magnesia	—	—
	99.98	99.80

The exploitation of the Indian magnesite is as yet in its infancy, but with the immense quantities of such excellent mineral available there is only needed the erection of suitable plant on a sufficiently large scale to make this a very large and profitable business.

DISCUSSION.

Mr. E. GRANT HOOPER asked if the author had any experience in connection with the actual use of the flooring of which a specimen was exhibited and which he understood was made with a mixture of magnesium chloride and calcined magnesia. One might anticipate from the known character of magnesium chloride that there would be some corrosive action if the material were in contact with metal, especially iron; and he should like to know if the author had met with any result of that kind.

Mr. OSCAR GUTTMANN asked if the author was quite certain that the Styrian magnesite, of which he gave an analysis, contained 11.59 per cent. of impurity.

Dr. R. SELIGMAN asked if he was correct in understanding that the dead-burnt magnesia showed a tendency to re-absorb water? He should also be glad of any details about the regenerative gas fired kilns which were being used for calcining magnesite.

Mr. CLAYTON BEADLE asked if this flooring was laid *in situ*, like Val de Travers asphalt, or made in blocks like the specimens shown, and then put down.

Mr. DAVIS asked if the floor covering was impervious to water.

Mr. H. H. DAINS in reply, said he did not think the magnesite could be used as a sort of reinforced concrete in connection with steel, but, once the material had set, like the specimen shown, there should be no action on metals, provided the metal and cement were kept dry at the point of junction. The material certainly could be used for flooring without damage, and it was largely used under various patent names in London and on the Continent. The material was laid *in situ*—not made into blocks and laid down. Various colours might be introduced into it. Where sawdust was used, the most convenient method was to mix it dry with the caustic magnesite, make plastic with magnesium chloride solution and then lay it in position. The magnesite cement formed was very good, provided it was not placed entirely under water. So long as it was exposed to atmospheric changes it was all right; but if it were kept continuously under water he thought the magnesite would gradually disintegrate and the cement would lose its properties. For walls and building materials it had proved quite satisfactory. There were buildings in London which had been up for some years without any deterioration. The regenerative gas kiln was an ordinary shaft kiln with regenerators.

Nottingham Section.

Meeting held at Nottingham on Wednesday, April 28th, 1909.

MR. O. QUIBELL IN THE CHAIR.

DETECTION AND ESTIMATION OF CHLORIDE IN PRESENCE OF BROMIDE BY THE USE OF DILUTE NITRIC ACID, AND ESTIMATION OF IODIDE, BROMIDE, AND CHLORIDE IN MIXED SOLUTION.

BY R. M. CAVEN, D.S.C., F.I.C.

It was shown by Kebler (J. Anal. Appl. Chem., 1892, 6, 569) that when concentrated nitric acid is added drop by drop to a mixed solution of bromide and chloride, the bromide is oxidised on heating, without appreciably affecting the chloride. Benedict and Snell (J. Amer. Chem. Soc., 1903, 25, 809) have employed 5*N* nitric acid for the same purpose, showing that as little as 0.3 c.c. *N*/100 sodium chloride solution, *i.e.*, 0.1 mgrm. of chlorine, can be detected after eliminating a large excess of bromide, as well as iodide. These authors have thus shown that this method of detecting chloride is at least 10 times as delicate as the chromyl chloride method; and it is certainly more convenient. In spite of this, however, they rejected the method for reasons which will be stated later. Further, this method is preferable to the use of permanganate or dichromate for the oxidation of bromide, because a colourless solution remains to be tested directly for chloride.

Detection of chloride.—To a small volume of the concentrated solution of the mixed alkali halides 10 or 15 c.c. of dilute nitric acid (1 vol. acid of 1.42 sp. gr. to 3 vols. water) are added, and the liquid is boiled in a porcelain dish. The liberated bromine quickly leaves the liquid, and the last traces appear within the bubbles at the surface, so that it is at once seen when the solution is quite free from bromine, and ready to be tested for chloride. More dilute nitric acid should be added, if necessary, after

boiling for a little time, to prevent the concentration rising much; otherwise chloride will be oxidised and lost.

The method is not so satisfactory for detecting traces of bromide, since the liberated bromine may be vaporised by heating before it is seen. Amounts as small as 2 mgrms., however, colour the nitric acid on heating just to boiling and allowing to stand for a minute. If smaller quantities than this need to be tested for, it is better to add a little potassium iodate, as recommended by the above authors. All the bromine is then liberated at atmospheric temperature, in nitric acid solution; and it is accompanied by one-fifth of its equivalent of iodine, which deepens the colour and makes the reaction more sensitive.

Estimation of chloride.—Benedict and Snell (*ibid.*) did not employ the nitric acid method for the qualitative or quantitative separation of bromide and chloride, because they found that when this acid was used to oxidise iodide as well as bromide, the distinction between the two was not sharp, and also because a small quantity of iodic acid was sometimes formed by the oxidation of the liberated iodine. It will be shown subsequently how iodide, when present, may be detected, estimated and eliminated, so that dilute nitric acid may in all cases be used to separate bromide from chloride.

Strength of nitric acid.—It was found by a number of experiments that the acid of most suitable strength is made by mixing one volume of 1.42 acid with three volumes of water. If the acid is weaker than this, evaporation is necessary before all the bromine is liberated; if stronger, an appreciable amount of chlorine will be lost.

Details of the process.—A measured volume of the solution of the mixed halides, or a weighed quantity dissolved in a measured volume of water, is placed in a clear white glass distilling flask of 200 c.c. capacity, and there are added 25 c.c. of concentrated nitric acid so diluted that the total volume of the liquid in the flask is 100 c.c.

The dilute acid may be added through a tap funnel which pierces a doubly bored cork fitting the neck of the flask. The stem of the funnel nearly touches the bottom of the flask, and through the other hole in the cork passes a thermometer which is suspended in the liquid. The delivery tube of the flask is connected with a wash bottle containing a little water, and this in turn is joined to a water pump, so that air can be drawn through the solution in the flask in order to displace the liberated bromine.

On heating the solution in the flask, while air is gently drawn through it, bromine is set free, the solution rapidly deepening in colour as the temperature approaches 80°. Boiling for one minute suffices to complete the reaction, and then the source of heat is removed, and a brisk current of air drawn through the solution as it cools. At the end of about five minutes, or even in less time, the solution will be perfectly colourless, and is then ready for the estimation of the chloride. It is well, however, to continue the aspiration for another minute after the liquid appears colourless. If all the bromine had not been liberated when the heat was removed, the decolourisation of the solution would be much slower. The rapid fading of the colour is therefore a sign that oxidation is complete.

For the estimation of chloride, excess of standard silver nitrate is added, and the excess titrated with ammonium thiocyanate, according to the method of Volhard, after the silver chloride has been filtered off.

The bromide present is estimated by difference, after titration of the total halide by the ordinary method.

Results.—The following results have been obtained:—

Weight of potassium chloride taken.	Weight of potassium bromide added.	Weight of potassium chloride found.
gm.	gm.	gm.
0.1	1.0	0.1004
0.2	1.0	0.2007
0.5	1.0	0.5004

The potassium bromide employed was Kahlbaum's, but it was not quite free from chloride. By two estimations of this salt by the above process, 10 grams being taken for each estimation, 0.085 and 0.081 per cent. of potassium

chloride was found. This correction has been applied in the above results and in those that follow.

In the following estimations the amount of bromide has been obtained by difference, the total halide being titrated either in neutral or acid solution.

A	Taken.	Found.	
		(i.)	(ii.)
Potassium chloride	0.1601	0.1602	0.1599
Potassium bromide	0.1908	0.1921	0.1922

B	Taken.	Found.		
		(i.)	(ii.)	(iii.)
Potassium chloride	0.1181	0.1188	0.1191	0.1181
Potassium bromide	0.1562	0.1554	0.1551	0.1565

[In example B three separate estimations of potassium chloride were made from the same solution; and the mean of two titrations of the total halide, one done in neutral, the other in acid solution (29.01 and 28.95 c.c. $N/10$ silver nitrate respectively) was used for the three estimations of potassium bromide by difference. In (i.) and (ii.) the solution was aspirated for about five minutes after boiling for one minute; in (iii.) aspiration was continued for seven minutes.]

If the above directions are carefully carried out the loss of chlorine which occurs is less than can be estimated by an ordinary volumetric process, and accurate results can always be obtained. The process is rapid, indeed the removal of the silver chloride by filtering, which is necessary before titration with thiocyanate, is the most lengthy part of the operation. This filtering may of course be avoided by titrating the chloride directly in acid solution, employing the shaking method.

The process is convenient for determining the purity of commercial specimens of potassium bromide, which often contain chloride, or it might be employed for the valuation of Kelp liquors. It is less well adapted for estimating small quantities of bromide in chloride, because, if large quantities of the latter are taken for estimation, some chloride will be lost by oxidation, even if the concentration of the solution is not sufficient for hydrogen chloride to be evolved on boiling. (Solutions stronger than $N/2$ lose hydrochloric acid on boiling.)

For example, 1 gram of potassium chloride was heated with 100 c.c. of dilute nitric acid in the usual way, and the evolved vapours led through silver nitrate solution. An appreciable quantity of silver chloride was precipitated; although when the same quantity of potassium chloride was heated with dilute sulphuric acid no chlorine passed over.

Estimation of iodide, bromide and chloride in mixed solution.

The volumetric estimation of iodide, bromide, and chloride necessitates three operations, two of which are the titration of total halide, and of the remaining chloride, after removal of iodide and bromide. For the third operation the choice lies between two possible modes of procedure, which are: (a) elimination of iodide, followed by titration of the mixed bromide and chloride, so that iodide is determined by difference; (b) direct estimation of iodide, and determination of bromide by difference. Apart from experimental considerations, the latter method is preferable, because the equivalent of bromine being less than that of iodine, the proportional error in titration is not so great. Moreover, when iodide is titrated independently, the amount of the substance taken can be adjusted to the proportion of this constituent present. Both methods, however, have been employed with success.

Titration of total halide.—For the titration of total halide the use of chromate indicator in neutral solution would naturally be adopted, but I prefer to add excess of standard silver nitrate in presence of dilute nitric acid, to filter off the precipitate of mixed silver halides, and titrate the excess of silver by Volhard's thiocyanate method. This gives a

sharper end reaction than the titration in neutral solution, since in the latter case the yellow silver iodide somewhat masks the colour of silver chromate.

Elimination of iodide by nitrous acid.—For the elimination of iodide the well known reaction with nitrous acid may be employed. A weighed quantity, or a small measured volume of a solution of the mixed halides is placed in a 200 c.c. distilling flask, and acidified with 2 or 3 c.c. of dilute sulphuric acid. About 0.5 gm. of the purest obtainable sodium nitrite, dissolved in a little water, is added, the solution is heated, and air aspirated through it for a few minutes till the liberated iodine has disappeared, and the solution is colourless. The solution is then ready for titrating the mixed bromide and chloride; or for oxidising the bromide with dilute nitric acid, as described above, so that the remaining chloride may be titrated. It must be observed, however, that sodium nitrite nearly always contains more or less chloride; the amount of chloride in the specimen used must therefore be estimated and allowed for.

Direct estimation of iodide.—In order to estimate iodide directly in presence of bromide and chloride, a reagent must be employed which oxidises hydriodic acid without affecting hydrobromic or hydrochloric acid. Ferric salts are known to possess this degree of oxidising power; and a volumetric process depending on the distillation of iodide with acidified iron alum solution has already been employed (*vide* Treadwell's "Analytical Chemistry," Vol. II., English Edition, p. 517). There is no need, however, to collect the iodine; for an accurate estimation of iodide can be made by boiling the mixed halide solution with dilute sulphuric acid and excess of iron alum until no more iodine vapour is evolved; and then cooling the solution, and titrating the ferrous iron produced by reduction by means of standard dichromate. Care must be taken, however, not to use a large excess of iron alum, for if the remaining ferric salt is too concentrated its presence masks the end of the reaction with ferrieyanide, owing to the brown colour of ferric ferrieyanide.

Elimination of iodide and bromide without the use of nitrous acid.—If iodide is estimated directly according to the method described above, the use of nitrite may be avoided; and this is an advantage, since no chloride need then be introduced by means of the reagents used. Since iodide and bromide are both to be eliminated without necessarily discriminating between them, in order that the residual chloride may be titrated, it might be thought that they could be got rid of together by heating with dilute nitric acid. This is satisfactory enough for a qualitative separation: for even if a little iodic acid is produced, as Benedict and Snell found (*J. Amer. Chem. Soc.*, 1903, 25, 809), the presence of a large amount of dilute nitric acid will entirely prevent the precipitation of silver iodate.

When, however, iodine, liberated on warming iodide solution with dilute nitric acid, is rapidly removed by aspiration of air, not a trace of iodic acid has been detected; for, after neutralising the nitric acid, and then adding acetic acid and potassium iodide, no iodine is liberated.

It is for another reason that it is undesirable to attempt to remove both iodide and bromide by means of nitric acid. When such an attempt is made, whilst the liberated iodine appears to be rapidly removed by aspiration, the colour developed by the liberation of bromine fades very slowly from the solution, so that 15 minutes or more may elapse after the source of heat is removed, before the solution becomes colourless; or it may even be necessary to heat the liquid again during aspiration. Since such a lengthened treatment is likely to result in loss of chloride, this method of eliminating iodide and bromide together was abandoned.

In order, however, to determine the cause of this anomalous behaviour of the mixed halides with dilute nitric acid, the following experiments were performed:—

(i.) 10 c.c. of $N/10$ potassium bromide solution were heated with 90 c.c. of dilute nitric acid containing 25 c.c. of 1.42 acid; and, after one minute's boiling, the solution became colourless in 24 minutes when air was aspirated through it as it cooled.

(ii.) 0.1 gm. of potassium iodide was treated in the same way, and the solution became colourless after three minutes' aspiration.

(iii.) 10 c.c. of $N/10$ potassium bromide solution, and 0.1 gm. of potassium iodide were similarly treated with dilute nitric acid; and after 15 minutes' aspiration a faint yellow tinge still remained in the liquid. Moreover, the colour faded so slowly that it would be difficult to be certain when it disappeared.

(iv.) Experiment (iii.) was then repeated, and, after aspirating for five minutes, the yellow liquid in the flask was cooled and shaken with carbon disulphide in a separating funnel. The carbon disulphide was coloured reddish brown, this colour being distinct from that caused either by iodine or bromine. On shaking with sodium hydroxide solution, acidifying the aqueous layer with dilute sulphuric acid, and adding sodium nitrite, a little iodine was liberated which coloured starch blue.

It is concluded from these experiments that bromide of iodine, IBr , is formed when dilute nitric acid is heated with a mixture of iodide and bromide, and that this compound is displaced less readily from nitric acid solution than either iodine or bromine alone.

Oxidation of iodide by hydrogen peroxide.—P. Jannasch and Fr. Zimmermann (Ber., 1906, 39, 196–7) have shown that only iodine is liberated from a mixture of iodide, bromide and chloride by hydrogen peroxide in presence of acetic acid; and P. Jannasch has also shown (Ber., 1906, 39, 3655–3659) that by the use of dilute sulphuric acid with hydrogen peroxide the whole of the bromide may eventually be oxidised and removed. Either of these dilute acids may be used in the present case; and for each estimation 10 c.c. of $2N$ acetic acid, or 2 c.c. $2N$ sulphuric acid have been employed. When sulphuric acid is used the action is rather more rapid than with acetic acid; but five minutes suffice for the removal of all the iodine even when acetic acid is used with hydrogen peroxide, and the liquid, after being boiled, is kept hot while air is aspirated through it. A slight objection to the use of dilute sulphuric acid is the fact that it causes a little bromine to be liberated so that the solution does not become quite colourless. This does not invalidate the result, however, since all the bromide is subsequently to be oxidised by dilute nitric acid.

Merck's or Kahlbaum's hydrogen peroxide may be employed; both are quite free from chloride; 0.5 c.c. of the 30 per cent. solution suffices for an estimation.

Summary.—The processes finally recommended for the estimation of iodide, bromide and chloride in a mixed solution are as follows:—

(i.) Titration of total halide in acid solution by Volhard's method.

(ii.) Estimation of iodide by titrating with dichromate the ferrous iron produced on boiling the mixed halide solution with iron alum.

(iii.) Titration of chloride in nitric acid solution after successively eliminating iodide by hydrogen peroxide in presence of acetic acid, and bromide by dilute nitric acid.

(iv.) Estimation of bromide by difference.

Results.—

I. Iodide eliminated by nitrous acid and estimated by difference.

	Taken.	Found.	
		(i.)	(ii.)
(a) Potassium iodide	0.1596	0.1599	0.1599
Potassium bromide	0.1518	0.1510	0.1508
Potassium chloride	0.1019	0.1014	0.1015
(b) Potassium iodide	0.1519	0.1518	0.1543
Potassium bromide	0.1935	0.1934	0.1929
Potassium chloride	0.1009	0.1001	0.1007

The difference between the two estimations of iodide in (b) may be attributed to experimental error. A small volume of the solution must necessarily be taken for the titration of the total halide, and of the volume of decinormal silver nitrate employed a relatively small amount represents iodide owing to the high equivalent of iodine.

II. Iodide estimated directly, bromide by difference.

	Taken.	Found.	
		(i.)	(ii.)
(a) Potassium iodide	0.1013	0.1013	0.1013
Potassium bromide	0.1923	0.1938	0.1922
Potassium chloride	0.1021	0.1028	0.1037

In (i.) iodide was eliminated by hydrogen peroxide in presence of dilute sulphuric acid.

In (ii.) iodide was eliminated by nitrous acid.

(b) Iodide eliminated by hydrogen peroxide and dilute sulphuric acid.

	Taken.	Found.	
		(i.)	(ii.)
Potassium iodide	0.1382	0.1379	0.1384
Potassium bromide	0.1446	0.1455	0.1451
Potassium chloride	0.1041	0.1033	0.1027

(c) Iodide eliminated by hydrogen peroxide and dilute acetic acid.

	Taken.	Found.
Potassium iodide	0.1102	0.1102
Potassium bromide	0.1092	0.1091
Potassium chloride	0.1145	0.1149

Of the numerous processes which have been employed for the estimation of mixed halides that of Benedict and Snell (J. Amer. Chem. Soc., 1903, 25, 1138) cannot be excelled for accuracy. These authors, however, do not say how long their process takes to carry out.

With regard to the final method described in the present paper, it may be stated that when the standard solutions had been prepared, and also 100 c.c. of the solution of the mixed halides, 10 c.c. of which were taken for each estimation, the above results [II. (c)] were obtained in exactly one hour.

DISCUSSION.

Mr. J. M. WILKIE thought that the superior accuracy of the Volhard method over that of Mohr was not solely due to obscuration of the end point by the yellow silver iodide, but to the fact that in neutral solution, silver nitrate or alkali iodide might be so precipitated and so lead to uncertain results. Some experiments he had made though they were not wholly conclusive supported this contention (*cf.* Treadwell, Vol. 2, p. 537). He was highly interested in the fact that bromine and iodine could not be removed in one operation by boiling with nitric acid of the specified strength. Had the author made any special investigation of this point? He thought the difficulty might be got over by the successive addition of further amounts of either bromide or iodide preferably as their hydrogen salt when the main reaction was over. With regard to the decomposition of iodides by means of hydrogen peroxide in acetic acid solution, did the author consider the reaction went to completion?

Mr. T. F. HARVEY said that the author's work would appear to provide a delicate and rapid method for the detection of chloride occurring as an impurity in potassium and other bromides; no convenient method had hitherto been devised, and a test which was both rapid and delicate was greatly needed. With reference to the possible oxidation and loss of chlorine in quantitative work, if present in too large quantity, he would like to know what concentration of chlorine Dr. Caven considered would form a safe working limit.

Dr. CAVEN said, in reply, that he was aware that precipitated silver iodide was believed to adsorb silver

nitrate or alkali iodide from solution; but whether the difficulty of obtaining accurate results in titrating an iodide with silver solution was entirely attributable to this cause he did not know. With regard to the removal of bromide of iodine by the addition of more bromide or iodide, he did not think this method was advisable even if it might be effective. The important consideration is the removal of bromide and iodide as speedily as possible so as not to oxidise chloride, and the addition of more bromide or iodide would necessarily retard this removal. The oxidation of iodide by hydrogen peroxide in acetic acid solution is complete, for Jannasch (*ibid.*) used this method for estimating iodide.

In reply to Mr. Harvey, he preferred to use not more than 0.2 gram. of alkali chloride in presence of bromide and iodide, dissolved in 100 c.c. of dilute nitric acid. Probably 0.5 gram. might be used without loss, but if more than this amount were employed oxidation of chloride would take place.

MR. O. QUIBELL IN THE CHAIR.

TESTS FOR THE ACTION OF CHLORIDES ON CAST-IRON.

BY E. J. R. CARULLA.

The fact that some chlorides attack iron and that ultimately they corrode it all away is well known. Anyone however who deals with chlorides in manufacturing operations will not find in chemical literature those cautions that after a short experience he might be led to expect.

Having occasion to treat ferrous chloride during the manufacture of certain products from ferrous liquors, the author some time ago examined its action on cast iron. The method adopted was the immersion of pieces chipped from certain pig irons with the intention of selecting those that were least acted on. The method of sampling was a rough one, but it proved to be sufficiently accurate for the purpose. The more regularly-shaped pieces were carefully measured to find as nearly as might be the area exposed to the surface of the liquor. The unit of area chosen was the square eighth of an inch ($\frac{1}{8}'' \times \frac{1}{8}''$).

Table I. gives the result of two days' immersion in a mixture of one part of ferrous liquor which still contained a little free hydrochloric acid, and three parts of water. After immersion of the pieces of iron, the whole was heated for half an hour and then put aside for two days, when the pieces of cast iron were taken out, washed, dried and re-weighed with the results indicated.

TABLE I.

Brand of cast iron.	Surface units $\frac{1}{8}'' \times \frac{1}{8}''$	Weight, grms.		Loss.	
		Original.	After immersion.	Total grm.	In millionths of a grm. per unit of area.
1	153	16.351	16.329	0.022	143
2	93.5	11.167	11.134	0.033	353
3	167	19.855	19.818	0.037	222
4	65	5.473	5.450	0.023	354
Hematite.	175	37.073	37.045	0.028	160

The piece of hematite was not from the pig. It was chipped off a plate that had been once through the cupola.

A further test was then carried out on the same pieces of iron, but immersing them in a mixture of one part neutral ferrous chloride and three parts water. The whole was heated for 85 minutes and then put aside for three days. The results are shown in Table II. There would really be some slight difference in the surface units, but the amount could not be practically measured, and in any case no error of importance is introduced by taking the original numbers.

TABLE II.

Brand.	Surface units.	Weight, grms.		Loss.	
		Before immersion.	After immersion.	Total grm.	In millionths of a grm. per unit of area.
1	153	16.329	16.264	0.065	425
2	93.5	11.134	11.085	0.051	545
3	167	19.818	19.747	0.071	425
4	65	5.480	5.416	0.064	523
Hematite	175	37.045	36.965	0.080	457

Judging by the values in the last column, the greater action that took place in the experiments recorded in Table II. seems to have altered the relative resisting capacity of the various irons. The character of this change is made more evident by plotting these numbers from the last column of both tables.

It would appear that in the second set of experiments an action nearly equally affecting the more corrodible irons had taken place, in addition to the original action as shown in Table I., the power of resisting which they still retained in varying degrees. One can suppose that these three samples were equally acted upon during the prolonged period of heating, namely 85 minutes, and that their different resisting power only came into play at the lower temperature.

The effect on the more resistant irons according to Table I., viz., No. 1, and hematite, is most remarkable, for No. 1 becomes bracketted with No. 3 and the hematite quite loses its position.

As the experiments detailed in Table II. were conducted with a less acid liquor than those in Table I. it seems strange that the action should have been so much greater notwithstanding the longer time of exposure. It might be supposed that when once the ferrous chloride was saturated with iron no further action would occur. A reasonable explanation seems to be that oxidation of the iron in the chloride takes place with formation of free acid which attacks any metallic iron present, and such an action may go on for any length of time.

Similar difficulties are met with in connection with ammonium chloride, and it becomes of equal importance, when dealing with hot solutions of this salt, to find irons that will stand its corrosive action. The volatile nature of ammonia has enabled a rapid and easy distillation test to be devised. The iron to be tested is boiled in a flask with a solution of ammonium chloride and the resulting ammonia absorbed in standard acid. Three grms. of iron in drillings, 5 grms. of ammonium chloride and 150 c.c. of water are heated to boiling in the distilling flask, and the evolved ammonia is then collected in 10 c.c. of normal acid with 100 c.c. of water for exactly 15 minutes. As a check a second receiver can be got ready with the same amount of acid, and the ammonia collected from the same mixture for another 15 minutes. It will be found that the difference is very slight between the two tests if the boiling has been kept on with the same vigour throughout. The experiments, detailed in Table III., made with drillings from No. 4 pig iron show how regular the evolution of ammonia is and how entirely it depends on the amount of iron used and the time. In all the experiments the same amount of ammonium chloride was employed, viz., 5 grms.

TABLE III.

Cast iron used, grms.	Time, minutes.	Ammonia produced in grms.	
		Total.	In 15 minutes.
1	26	0.019	0.011
2	16	0.0299	0.028
3	15.5	0.0352	0.034
4	15	0.044	0.044

From the above there seems no reason for choosing one particular weight of iron more than another with which to make the test. When one considers however that the action is a surface one and that drillings vary in size even in the same sample of cast-iron, it is obvious that the larger the quantity weighed for the test the nearer will the result be to the truth. Three grms. is a quantity easy to handle, and seems sufficiently large for the purpose.

Experiments on irons obtained from various sources have given the results detailed in Table IV.

TABLE IV.

Cast irons.	c.c. of normal hydrochloric acid neutralised during		Average ammonia evolved in 15 minutes.
	First 15 minutes.	Second 15 minutes.	
A	3.50	3.50	grms. 0.0595
B	2.68	2.65	0.0452
C	1.13	1.75	0.0245
D	1.10	1.60	0.0229
E	1.60	1.65	0.0276

It is remarkable that the iron A which was drilled from the pig should be the most corroded, since it was put forward as a specimen of acid-resisting iron. Sample B was from an evaporator plate, C, D, and E were all drillings sent by manufacturers of chemical plant as from iron suitable for such purposes. This the tests seem to confirm.

Differences that may be thought considerable may be observed, in the case of samples C and D, between the evolution of ammonia in the first and second periods of 15 minutes. These are probably due to the mixture in the distilling flask not having been brought to a sufficiently high temperature in the preliminary heating before beginning to absorb. As before noted, this is a point of considerable importance, for when carefully attended to, concordant results are generally obtained.

Table III. shows that the tests need not be carried on for exactly 15 minutes, as was done with those recorded in Table IV. A calculation can easily be made to bring the results to any standard period of time that may be adopted.

For more exact results, and especially with irons that show any considerable resistance to the action of ammonium chloride, and where consequently the quantity of acid neutralised is small, a correction may be made for the dissociation of the salt itself when boiling. Five grms. of ammonium chloride dissolved in 150 c.c. of water and kept boiling for one hour in a Jena flask evolved 0.001 gm. of ammonia, which represents a correction of 0.00025 as necessary for 15 minutes, the time adopted for the tests detailed above.

From the data obtained by this test the amount of iron that goes into solution can be easily calculated, and consequently the time during which any particular casting is likely to remain fit for its purpose, when employed in apparatus to deal with ammonium chloride liquors.

It is just to mention that Mr. G. K. Davis refers to an

experiment in which wrought iron was heated in an ammonium chloride solution and the iron itself was weighed to ascertain the effect (*Journal of Iron and Steel Inst.*, 76, 81).

DISCUSSION.

The CHAIRMAN said that local water caused considerable corrosion of boiler plates. In glue-making, again, severe pitting took place in the plates of the vessels used.

Mr. W. G. TIMMANS asked whether the author had confined his experiments to pig-iron, or had he also tested actual castings? He thought that the question went beyond the chemical composition of the irons. The temperature at which the castings were run had, he thought, much to do with their soundness, and consequently with their resisting power to chemical action. He had had cause to complain of castings one inch thick that were quite porous.

Dr. R. M. CAVEN remarked on the action of metallic chlorides which, with the exception of those of the alkalis, were almost all hydrolysed by water, especially at high temperatures. This would occur in the case of ferric chloride, which would seem to explain some of the experiences referred to in the paper.

Mr. J. GOLDING asked whether the tests had been brought into line with practical experience. How far were the samples dried, and could the author say what amount of water cast-iron would take up? He had knowledge of experiments conducted on nodules of iron from the coal-measures which were immersed for some time in water, and then frozen, to break them up, in order to see their structure. Might there not be in cast-iron these microscopical fissures between the crystals?

Mr. H. ROGERS suggested that a comparison of the analytical results with those of the author's tests would be most interesting, and possibly throw light on what seemed anomalous.

Mr. T. F. HARVEY asked whether any parallel tests had been made with the immersion and the distillation tests.

Mr. F. J. R. CARULLA, in reply, said that the action of chlorides was more rapid on wrought than on cast iron, so that probably that would account for the experiences of their chairman. These tests had all been applied only to cast-iron, on both pig-iron and to samples drilled from the actual castings. He would not like to say that a good sound casting would take up water, but of course a porous casting would do so. He had selected sound pieces, which were thoroughly washed and dried before weighing, to ascertain the loss after immersion in the ferrous liquors. Dr. Caven's remarks were most valuable, and evidently ammonia must not be included with the alkalis for the chloride certainly hydrolysed. The original samples had been dispersed so that no parallel tests were made, the distillation test being of comparatively recent origin. The latter was intended to show the action of ammonium chloride, whereas the immersion test was for ferrous chloride, both liquors being treated at different stages of the process. An analytical comparison with the tests described would certainly be interesting, but time had not allowed of this being done. He might say, however, that typical analyses of the various pig-irons named might be found in metallurgical books.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—8d. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs Bourgeois, Paris (3e.).

German.—1 mark each (with full particulars) to Kaiserlich Patentamt, Berlin, Germany.

I.—PLANT, APPARATUS, AND MACHINERY.

PATENTS.

Furnaces or apparatus for supplying heated air for industrial purposes. J. R. Farbridge, Whitley Bay. Eng. Pat. 7403, April 3, 1908.

Air is forced by a fan into a chamber situated in front of the furnace and which can be put into communication,

by means of valves or slides, with the ash-pit of the furnace, with a series of perforated heating tubes which supply secondary air to complete the combustion of the gases, and with a chamber or chambers from which the air passes through the heating tubes proper, placed in the path of the products of combustion. The heated air passes from the heating tubes to one or more chambers situated between the heating tubes and the chamber supplying

air thereto, being in this way protected from loss of heat by radiation. The air supply chamber is of such a size that an effective pressure can be maintained therein so as to cause an even distribution of air through the tubes.—W. H. C.

Classifiers or separators for materials of different specific gravities. C. Churchill, Boston, Mass., U.S.A. Eng. Pat. 7841, April 8, 1908.

THE materials to be separated are delivered along with a stream of water into the bottom of the cone, *a*, through the pipe, *b*. The cone is provided with propeller blades, *n*, the pitch of which increases from the bottom upwards; these blades are mounted on the hollow shaft, *m*, which is free to rotate about a fixed shaft, *j*, supported by the frames, *i, h*. The cone is also provided with an overflow gutter, *j*, and with several valved outlets, *o*, fixed at different levels. The flow of the water causes the propeller blades to rotate and sets up centrifugal force within the cone. The lighter particles are carried upwards and over the top of the cone into the gutter, *j*, and the heavier particles are drawn off at different levels according to their specific gravities.—W. H. C.

Separating liquid and dirt from gases and steam by means of oblique currents, separators and catch chambers. H. O. Klausner, London. From C. F. Scheer and Co., Feuerbach, Germany. Eng. Pat. 8208, April 13, 1908.

THE steam or gas to be purified enters the apparatus in the direction shown by the arrows and is directed into the curved catchers, 2, by the angle pieces, 1. The semi-circular catchers, 2, have return flanges, as shown, which prevent the deposited matter from escaping back into the stream of gas or steam. The deposited liquids flow away by the openings, 3.—W. H. C.

Superheating steam; Apparatus for — applicable also for heating liquids. J. A. Marchant, Ashton-under-Lyne. Eng. Pat. 7635, April 7, 1908.

THE superheater consists of a number of pairs of concentric tubes ("field-tubes") connected to one or more headers. The interior tubes are carried by removable hollow caps so as to facilitate repairs. The tubes are so grouped that the steam is forced to circulate through several groups of tubes in succession. The superheater is connected by a tube containing mercury with a thermometer fixed at the front of the boiler, in order that the degree of superheating attained may be easily observed.—W. H. C.

Cleaning or washing smoke, and for inducing draught; Apparatus for —. J. Black, and A. H. and H. Lennox, Newcastle-on-Tyne. Eng. Pat. 14,693, July 10, 1908.

THE invention relates to improvements in the apparatus described in Eng. Pat. 27,917 of 1907. The smoke-stack, *a*, has an extension, *b*, closed at the top by the dished plate, *c*, and provided with openings, *d*, through which the smoke passes to the enlarged extension, *e*. The latter is contracted again to form the sectional conduits, *f, g, h*, and is closed below and provided with a drain-pipe, *t*. Curved baffles, *j, k*, open in the centre, are inserted between the sections, *f, g, h*. Water under pressure is delivered from the annular main, *l*, by the pipes, *m, q*, to the upwardly directed spraying jets, *n, r*. The water is discharged through the drain, *t*.—W. H. C.

Crate for carboys, demijohns, and the like.—D. G. Pinkney, London. Eng. Pat. 10,609, May 15, 1908.

IS a crate for carboys, demijohns, etc., having a frame-work box to contain the vessel, and a removable cover having arms adapted to be screwed into place for transit, or to serve as a base with the crate body pivoted on the arms for use,—the combination with the frame-work body, of expansive spring packing strips adapted to engage the sides of the vessel, and cleats secured on to the packing strips for retaining the vessel in position. A further claim specifies the use of pivoting pins, recessed

within the crate arms to accommodate them, and a cover for keeping them from protruding. When it is desired to empty the vessel, the cover is removed and forms a stand on which the crate containing the carboy is supported by trunnions, so that the vessel can be tilted to discharge the contents.—W. H. C.

Gas-fired shaft-furnaces. E. Schmatolla, London. Eng. Pat. 10,854, May 19, 1908.

THE claim is for the arrangement of the furnace described in Eng. Pat. 1168 of 1908 (this J., 1908, 1008), as a shaft-furnace for the continuous burning of materials, and for the provision of a cooling chamber beneath the fire-zone of such a furnace.—W. H. C.

Dry-kiln; Superheated-steam —, and method of drying materials [lumber] with superheated steam. D. E. Lain, Assignor to E. G. Jewett, Bellingham, Wash., U.S. Pats. 918,334 and 918,335, April 13, 1909.

(1). THE claim is for the combination of a drying chamber divided by a diaphragm into unequal parts, with a steam generator connected to the system, a superheater, a steam coil, and means for mechanically circulating the steam through the system. The system is closed at all points except the exhaust. (2). The drying process consists in supplying a quantity of steam to the system and then cutting off the supply and mechanically circulating the steam. The excess of vapour carried off by the steam is condensed and withdrawn from the system, and the steam is continuously reheated and returned through the drying chamber so long as any vapour is given off by the material under treatment.—W. H. C.

Mixing-machine. T. M. Phillips, Assignor to The Youngstown Steel Co., and E. L. Ford, Youngstown, Ohio, U.S. Pat. 919,074, April 20, 1909.

A ROTARY drum mounted on hollow journals is provided with lifting blades and with a longitudinal screen dividing it into two compartments, into which steam is conveyed through one of the hollow journals.—A. S.

Solution and precipitation processes; Apparatus for use in —. W. Hommel, Assignor to Metals Extraction Corporation, Ltd., London. U.S. Pat. 918,749, April 20, 1909.

SEE Eng. Pat. 27,017 of 1907; this J., 1909, 416.—T. F. B.

Rendering material of any kind proof against the action of moisture and chemical agents; Process for —. A. Kronstein, Karlsruhe, Germany. U.S. Pat. 919,031, April 20, 1909.

SEE Eng. Pat. 2679 of 1901; this J., 1901, 460.—T. F. B.

Separating solids from liquids; Apparatus for —. F. E. and A. S. Elmore, London. U.S. Pat. 919,144, April 20, 1909.

SEE Eng. Pat. 26,821 of 1907; this J., 1909, 194.—T. F. B.

Drying machine. J. Black, Newcastle on Tyne. U.S. Pat. 919,529, April 27, 1909.

SEE Eng. Pat. 12,087 of 1907; this J., 1908, 396.—T. F. B.

Concentrating solutions; Process of —. E. Monti, Turin, Italy. U.S. Pat. 919,616, April 27, 1909.

SEE Fr. Pat. 357,770 of 1905; this J., 1906, 113.—T. F. B.

Recovering vapours from volatile liquids; Apparatus for —. H. Diamanti and C. Lambert, Paris. U.S. Pat. 919,832, April 27, 1909.

SEE Fr. Pat. 372,888 of 1906; this J., 1907, 518.—T. F. B.

Acid-proof tank. U.S. Pat. 918,649. See X1B.

II.—FUEL, GAS, AND LIGHT.

Coal industry in the year 1907—1908; Position of the —. W. Bertelsmann. Chem.-Zeit., 1909, 33, 518.

THE production of coal, etc. (in metric tons), in Germany in 1905, 1906, and 1907, is shown in the following table:—

	1907.	1906.	1905.
Coal	143,222,886	136,479,885	121,298,607
Lignite	62,319,802	56,225,189	52,512,062
Coke	21,938,038	20,260,572	16,358,324
Coal briquettes	3,524,017		
Lignite briquettes..	12,890,461	14,500,851	13,009,682

The German imports and exports respectively of the different products in 1907 were:—Coal, 13,729,296 and 20,017,688; lignite, 8,963,103 and 22,065; coke from coal 558,695 and 3,790,642; coke from lignite, 25,526 and 1938; coal briquettes, 136,320 and 837,775; lignite briquettes, 59,084 and 422,360; peat, peat-coke, 15,214 and 25,746 metric tons. Statistics relating to the world's supply of coal are also given (see this J., 1909, 301).—A. S.

Coal-dust [in mines] and its treatment with calcium chloride. H. Hall. Trans. Mining Inst. of Scotland, 1908—1909, 31, 96—118.

THE author recommends the use of calcium chloride for laying dust in coal mines, the salt being used either in the form of a concentrated solution (48°—50° T.), or as fine dry powder in seams where watering cannot be resorted to. It is stated that one application of the salt every three months is sufficient. Comparative tests as to the corrosive action of calcium chloride solution (43° Tw.) and St. Helens town water on iron, showed that the metal lost three times as much in water as in the calcium chloride solution; also that iron exposed alternately to water and air rusted far more quickly than when exposed to calcium chloride solution and air alternately.—A. S.

Fuel from peat. M. Ekenberg. Iron and Steel Institute, May, 1909. [Advance proof.]

RAW peat can be converted into fuel without air-drying by a process of "wet-carbonising," which consists in heating the peat-pulp under pressure to 180°—220° C. and removing the bulk of the water from the product by subjecting the mass to a pressure of about 50 atmospheres. The water cannot be separated from the raw peat by pressure on account of the presence of a slimy "hydro-cellulose" which fills and surrounds the cells. This substance is decomposed when heated with water to 150° C., hence the "wet-carbonised" peat can be dried by pressure. The weight of water remaining in the pressed peat is less with higher temperatures of carbonisation; with a pressure of 20 atmospheres, the pressed peat contains 1½ lb. of water per lb. of peat substance if carbonised at 180° C., or 1 lb. if carbonised at 200° C. Other changes which occur during the heating are an increase in the calorific power and in the percentage of carbon in the peat substance, owing to the separation of part of the hydrogen and oxygen as water. The heating is carried out in a regenerative manner by forcing the peat-pulp continuously through a battery of tubes in a heating chamber; the cold pulp passes through jackets which surround the tubes conveying the hot pulp from the heating chamber to the press. The pressed peat, after air-drying for one week, contains 25 per cent. of moisture, or less moisture than the best ordinary air-dried peat. The pressed peat can be completely dried by heating, the fuel required for "wet-carbonising" and final drying corresponding to about 15 per cent. of the peat substance in each case, or 30 per cent. in all. The dried peat has a calorific power of 11,000 British thermal units per lb., and can be converted into briquettes by the usual processes. The total fuel consumption in making peat briquettes from the raw peat is about 37 per cent. of the peat substance, and with a daily output of 100 tons, the cost of the briquettes is estimated at 6s. 8d. per ton,

without recovery of ammonia from the fuel used. The briquettes burn with a long luminous flame, without soot or smoke, and leave 4 to 5 per cent. of ash. The specific gravity of the briquettes is 1.29 to 1.35, and their heating value is, bulk for bulk, equal to that of coal. The evaporative effect when used for steam raising is high as compared with coal of the same heat value, on account of the smaller quantity of air required for combustion. The "wet-carbonised" peat can be converted into peat-charcoal, and the peat briquettes similarly treated yield a very strong charcoal, or "peat-coke." This "peat-coke" has a crushing load of 300 kilos. per sq. cm., and is suitable for use in blast-furnaces. "Wet-carbonised" peat can also be used in gas-producers, and yields, per ton of dry peat substance, 39,500 cub. ft. of gas having a calorific power of 160 British thermal units per cub. ft., together with 4.2 per cent. of tar, and 4.3 per cent. of ammonium sulphate, 79 per cent. of the nitrogen being recovered. If the gas is used in engines driving electric generators, the cost of current is as low as when generated from water power. Finally, the "wet-carbonised" peat heated in coal-gas retorts or by-product coke-ovens, yields, per ton, 17,000–20,000 cub. ft. of gas of 15 candle-power, having a calorific power of 750–800 British thermal units per cub. ft., and therefore suitable for illumination and heating.

—A. T. L.

Combustion; Influence of surfaces upon — W. A. Bone. J. Gas Lighting, 1909, 106, 300–303.

MIXTURES of combustible gas (hydrogen, carbon monoxide) and oxygen were circulated over different solid substances maintained at a constant temperature below the ignition point of the gaseous mixture. The temperatures employed for mixtures of hydrogen and oxygen were:—platinum, 160–180° C.; porous porcelain and magnesite, 430°; silver, 400°; gold, 250°; nickel, 230°; copper, 204°; nickel oxide, 160°; and iron oxide, 200° C. In all cases the rate of combination was accelerated by the presence of the solid substance. With a given substance, the rate of combination in the case of mixtures of the gases in stoichiometrical proportions was proportional to the pressure, but with excess of either component, the governing factor in most cases was the partial pressure of the hydrogen. With excess of hydrogen, not only was the initial velocity greater, but this was continually accelerated as combustion proceeded. The general result of the experiments was to show that the idea that surface combustion consists of a rapidly alternating series of oxidations and reductions of the surface, is untenable. The combustible gas, in most, if not in all, cases, is in some way, either by direct contact with the surface, or by some influence exerted by the surface on the gas not actually occluded, rendered active, and is then burned with extraordinary swiftness. In some cases, probably with copper, it is not the combustible gas, but the oxygen which is thus influenced. The rate at which the combustible gas which has been rendered active, is burned is very much greater than the rate at which the gas is rendered active, so that the latter is the controlling factor. Whilst under ordinary conditions methane burns at a rate twenty or thirty times quicker than hydrogen does, yet in contact with a solid substance, so great is the action of the surface on the hydrogen, that the latter is burned before the hydrocarbon is appreciably affected. The author's study of the effect of surfaces upon combustion leads him to conclude that in order to attain the highest efficiency in heating by gas, it is essential to introduce as much surface combustion as possible, that is, to proceed so that combustion takes place as far as possible in contact with the hot surface.

—A. S.

Iron carbonyl in coal-gas. J. N. E. Tonne, jun. J. Gas Lighting, 1909, 106, 87.

INCANDESCENCE mantles used with coal-gas produced in a new Dutch gas-works, were found to rapidly lose illuminating power and become covered with a yellowish-brown deposit. The author found this to be due to the presence in the gas of volatile iron carbonyl (see Mond,

this J., 1892, 750). The presence of the iron carbonyl was detected in the gas taken from the outlet of the tar extractor, and a small quantity of iron oxide was found in the water in the washer. The gas contained 7 per cent. of carbon monoxide, and it appears probable that the iron carbonyl was produced by the action of the carbon monoxide on the iron of the mains at a low temperature. Gas taken from the hydraulic main was free from iron, and hence the iron carbonyl was not produced at high temperatures. Iron carbonyl is not acted upon by dilute hydrochloric acid. When the gas was examined some weeks after the first occasion, less iron carbonyl was present, probably owing to the surface of the mains having become covered with tar and naphthalene, which would protect the iron from the action of the gas. (See also this J., 1900, 31, 521.)—A. S.

Incandescent mantles; Ramie — C. R. Böhm. Chem.-Zeitung, 1909, 33, 447.

RAMIE mantles, which were first introduced in 1897, have now almost entirely displaced cotton mantles in Germany, and it is estimated that ramie is now used for three-fourths of the world's production of incandescent mantles. Ramie mantles give a greater intensity of light than cotton mantles owing to the roughness of the thread compared with cotton, and whereas a cotton mantle loses its shape and gives only half the original light after a life of 100 hours, the light of a ramie mantle decreases only by 10 per cent. in the same time, and the average life is 600 hours. The ramie thread is stronger than cotton, so that a finer thread can be used. The collodionised mantles are quite strong enough to permit of export.—A. T. L.

PATENTS.

Lignite and peat; Process for utilising the briquetting (binding) properties of — A. Zindler. Fr. Pat. 395,385, Oct. 16, 1908.

LIGNITE and peat can be briquetted by means of the bituminous matter they contain. The claim is for the utilisation of this property to form briquettes with other bodies such as, for example:—Coal and coke dust, coal dross, iron filings and turnings, fluxes, blends, blast-furnace dust, pyrites, etc.—W. H. C.

Coal tar; Process of treating — in order to allow it to be used as a combustible. R. Garzón. Fr. Pat. 395,799, Oct. 29, 1908. Under Int. Conv., June 8, 1908.

THE tar is heated to render it more fluid and is then injected by an atomiser into the furnace by compressed air. Atomised water is injected into the furnace along with the tar to ensure regular and complete combustion.

—W. H. C.

Oven for the calcination of coal or other materials. L. Wirtz. Fr. Pat. 395,497, Oct. 20, 1908.

THE apparatus consists of a number of narrow vertical coking chambers separated by hollow walls through which the heating gases circulate. The ovens terminate above in a common charging and gas-collecting chamber and below in a common discharge chamber.—W. H. C.

Gas-producer. J. Fielding, Gloucester. Eng. Pat. 14,292, July 6, 1908.

THE producer, which is suitable for use with bituminous fuel, is worked with an upward draught, and the bulk of the gas is taken off by an outlet at a level where the fuel is incandescent, so that the gas contains only a small proportion of condensable matter. The bulk of the condensable gases are taken off at the top of the producer and burnt under a boiler to generate the steam required to prevent the formation of clinker in the producer.

—A. T. L.

Water- and coal-gas; Apparatus for manufacturing — H. W. Benner, Chambersburg, Pa. U.S. Pat. 918,727, April 20, 1909.

THE apparatus comprises a water-gas producer, a superheater, and a chamber containing a number of coal-gas

retorts surrounded by chequer-brickwork. Each part of the apparatus is connected to the other two parts by valved connections. During the air-blow in the producer, the products of combustion are passed through the chamber containing the retorts and then through the superheater, and during the steam-blow, the water-gas is passed direct to the superheater.—A. T. L.

Gas-producer for heating gas retorts or for other purposes. P. V. Parsy. First Addition, dated Nov. 5, 1908, to Fr. Pat. 393,810, Nov. 6, 1907 (this J., 1909, 131).

THE patent relates to means for preheating the air supply or the retort served by the producer. For this purpose a regenerator is arranged at either side of the producer in the lower part of the retort oven. The hot combustion products from the oven pass in a downward zigzag path between hollow horizontal partitions in the regenerators, and the air passes in an upward zigzag path through these partitions. The heated air is delivered from each regenerator through a horizontal burner pipe into the oven, where it meets the producer gas issuing from the horizontal branches of a central channel arranged along the top of the producer chamber.—A. T. L.

Gas-producers. C. Lefebvre. Fr. Pat. 395,510, Dec. 30, 1907.

THE gas-producer, which is adapted for use with wood and other vegetable fuels as well as with coal, comprises two chambers of refractory material formed within a single casing. The first chamber serves for the production of gas and the second, which is provided with a vaporiser, is packed with coke and serves as a dry scrubber. The fuel in the producer chamber rests on a horizontal or slightly inclined hearth, and a vertical grate is arranged at the front of the hearth. The gas leaves the producer chamber opposite to the grate, and passing downwards at the back of the hearth is led under the hearth of the scrubber chamber and enters the latter chamber at each side of the hearth. Dust is deposited by the gas in the space beneath the hearths of the two chambers, and the ashes and clinker on the hearth of the producer can be pushed over the back of the hearth into this space, which is cleared through doors at its ends. The upper part of the producer chamber is provided with a door, and air or steam can be admitted either at this door or through the grate, the producer working with a draught, or with a horizontal draught according to the nature of the fuel. With coal a horizontal draught is used, but with lignite or wood, a down-draught is employed and no steam is admitted. The lower part of the producer chamber is of smaller cross-section than the upper part, so that when the fuel is not too moist, the coke in the lower part of the chamber is kept incandescent by the rapid current of hot gas, without admitting air to the lower part of the producer. When very moist fuel, such as wood waste or olive marc is used, the steam and tar set free in the upper part of the producer chamber are drawn by an ejector through a surface condenser in which the steam is condensed, and the tarry gases are then mixed with hot air from the vaporiser and led back into the producer chamber. The hot water from the condenser is used in the washers. Other improvements relate to the construction of the grate and of the vaporiser. The grate consists of a series of horizontal plates, arranged one above the other so that the lower ones project further into the fire than the upper ones. A shallow trough is formed along the front edge of each plate, and the overflow water from the vaporiser is led to the uppermost of these grooves, and passes from each plate to the next below. With this arrangement the temperature of the fire can be controlled so that clinkers do not adhere to the grate. The vaporiser comprises a number of ranges of Field tubes, arranged in a contracted zone of the scrubber chamber. The tubes are fixed in a detachable plate which can be lifted out when the cover of the vaporiser has been removed. Each Field tube is provided with an inner tube which delivers air and water to the lower end of the Field tube. This inner tube is open at the top and is also pierced near the top for the entry of air horizontally. Above each range

of these tubes is a horizontal water-supply pipe closed at the end and pierced with a small hole at its highest point above each Field tube. The water escaping through these holes flows over the outer surface of the water-pipe and drops into the Field tubes from projections with rounded ends arranged above these tubes. In this way the water is fed regularly in conjunction with air to the bottom of each of the Field tubes.—A. T. L.

Gas producer. M. Castay. Fr. Pat. 395,790, Oct. 29, 1908.

To permit of the use of small or dusty coal, the upper part of the producer chamber is made in the form of an inverted truncated cone, the lower part being of the usual cylindrical form. The air passing upwards through the fuel maintains the necessary temperature in the cylindrical part of the producer, but the velocity of the upward current decreases progressively in the upper part of the producer until it is insufficient to carry away dust along with the gas. The fuel is supplied through a central hopper the position of which can be adjusted vertically. The depth of the column of fuel in the producer is determined by the position of the hopper, which is adjusted so that the surface of the fuel is kept at a red heat.—A. T. L.

Gas producer. A. C. P. Blanchard. Fr. Pat. 395,807, Jan. 7, 1908.

THE patent relates to producers of the kind in which the gas formed in a producer chamber passes through a hot column of non-bituminous fuel in a second chamber and there undergoes a partial reduction. The two chambers are formed in a single casing and are connected at their lower ends by a channel for the gases, arranged so as not to be obstructed by fuel. For this purpose the producer chamber, which is rectangular, is provided with a horizontal gas outlet near the base, opposite to a vertical or inclined grate at the front of the producer. This gas-outlet passage turns downwards and passes under the hearth of the reduction chamber, where it bifurcates and passing up by the sides of the hearth, leads horizontally into the lower part of the reduction chamber. The lining of the producer chamber at the side opposite to the grate projects so as to direct the descending fuel towards the grate and away from the gas inlet. A boiler or vaporiser is arranged in the top of the reduction chamber and is provided with an air inlet. The mixture of air and steam from the boiler, or hot air alone if desired, is led by a pipe to the producer chamber, to which it is admitted, with cold air if desired, by one or more of three valved inlets. One inlet is above the fuel column, the second leads to the grate, and the third opens into the gas conduit between the producer chamber and the reduction chamber. The apparatus may be operated with a forced blast of air, or by suction, and is suitable for all kinds of fuels.—A. T. L.

Ammonia from producer gas; Plant for recovering —. A. H. Lynn, Bromley, Kent. Eng. Pat. 8014, April 10, 1908.

THE washer, *a*, is constructed as shown in the cross-section (Fig. 1) and longitudinal section (Fig. 2) with a midfeather, *b*, and lute, *c*. The gas enters at *f*, into the chamber, 1, and is washed by spray produced by the dasher, *j*. It then passes through the opening, *e*, near the level of the liquid which fills the washer, into the second chamber, 2, again meeting the spray, and finally escapes through *d*. The gas from the producer passes first through a heat interchanger where it is cooled and heats the air, then through a washer where it is further cooled and heats the cooling water. It next passes through a second

similar washer where the ammonia is absorbed and then through a third washer which acts as a final cooler. The water from the first washer or water-heater is circulated by a pump through a similar washer through which air is aspirated. The air absorbs heat and vapour from the warm water which is cooled and returned, along with a quantity of fresh water to make up for that carried off by the air, to the first washer.—W. H. C.

Filters chiefly designed for use in the purification of gas. Kirkham, Hulett, and Chandler, Ltd., and S. Hersey, London. Eng. Pat. 9384, April 30, 1908.

THE patent relates to filters of the kind described in Eng. Pat. 7538 of 1906 (this J., 1907, 462). The grids are supported on notched bearers carried by vertical supports or trestles. In large filters, where more than two trestles are required, the intermediate trestles are provided with a double set of bearers to carry the abutting ends of adjacent sets of grid-bars; or single sets of bearers may be used, having wide notches to carry the overlapping ends of adjacent sets of grid-bars. The grid-bars of the highest and lowest tiers are made deeper than the others and notched on the underside where they rest on the notched bearers, this arrangement serving to brace the structure.—A. T. L.

Tar, dust, &c.: Apparatus for the extraction of — from gases. F. W. Burstall, Birmingham. Eng. Pat. 10,442, May 14, 1908.

THE apparatus is of the centrifugal type, and the "rotor" consists of a number of radial wires mounted upon a central hub. The flow of gas may be axially through the rotor, or from the centre to the circumference. Water is supplied near the axis of the rotor. The rotor fills the rotor chamber except for a collecting chamber at the periphery, and the gas, in passing through the apparatus, is subjected to a combined sifting and beating action by the wires of the rotor.—A. T. L.

Gas; Washer or cooler for freeing — from tar or dust and for cooling the gas. F. W. Burstall, Birmingham. Eng. Pat. 10,901, May 20, 1908.

THE apparatus comprises a horizontal cylindrical drum, rather more than half filled with water, and a series of parallel plates mounted on a revolving shaft arranged along the axis of the drum. Alternate plates are pierced near the axis and near the circumference, and the space between the circumference of the plates and the drum is sealed by a film of water under the centrifugal action of the revolving plates, so that the gas, in passing through the drum, is forced to take a circuitous path and is brought into contact with a large area of surface which is continually washed with water.—A. T. L.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Hydroacridin; Occurrence of — in coal-tar. H. Decker and G. Dunant. Ber., 1909, 42, 1178—1179.

SAMPLES of acridine from tars of various origin were used in the preparation of N-methylacridine. On treating a sample with an excess of dimethyl sulphate and adding sodium carbonate solution to the quaternary salt, there was an immediate formation of a gray crystalline precipitate which was insoluble in dilute hydrochloric acid. On distillation in a current of steam, this yielded a body melting at 96° C., and identified as N-methyldihydroacridine, first prepared by Pictet and Patry (Ber., 35, 2535). This was confirmed by its conversion into quaternary N-methylacridinium picrate, m. pt. 190° C. (Ber., 39, 2722). The authors regard this behaviour of the crude acridine as a proof of the occurrence in coal-tar of dihydroacridine first obtained artificially by Gräbe and Caro by the reduction of acridine.—C. A. M.

Paraffin content of petroleum as a criterion for judging the relative geological age of the same. M. Rakusin. Ber., 1909, 42, 1211—1215.

PETROLEUMS may be divided into three classes according to their behaviour to polarised light: (1), transparent; (2), semi-transparent; and (3), opaque. The first class comprises those oils which are transparent to polarised light in a 200 mm. tube (see this J., 1907, 678); and the third, oils which allow polarised light to pass (200 mm. tube) only when dissolved in benzene, benzine, etc., at a concentration of less than 1 per cent. In other words, in the case of oils of the third class, the coefficient of polarimetric opacity, or carbonisation constant (K) as the author prefers to term it, is less than 1, whilst it is 100 for oils of the first class. Oils with a carbonisation constant between 1 and 100 belong to the second class. The author has observed that oils with a relatively high carbonisation constant are also relatively rich in paraffin, and since the carbonisation constant decreases with increase in the geological age of the oil, he arrives at the conclusion that of the corresponding crude petroleum from a given district, those of more recent geological formation are richer in paraffin than the geologically older, opaque oils from a lower level. Evidence in favour of this view is cited.—A. S.

Petroleum from Saghalien. M. Rakusin. Petroleum, 1909, 4, 519—511, 806—810.

PETROLEUM has been found in the northern narrowest portion of the Island of Saghalien; in the eastern portion near where the river Ucha flows into the Okhotsk Sea; and in the southern portion about 200 miles south of the Gulf of Tschai, and 265 miles from Port Alexandrowsky, the chief town of the island. The northern deposit comprises the so-called "great asphaltum lake," together with other similar but smaller deposits. On the surface of the "lake" are holes or pits, in which, floating on the water therein, petroleum is found in layers 3½ ins. thick. Test-borings in this district showed that below the layer of asphaltum (9—21 ins. deep) were strata of greenish-gray clay alternating with greenish or brownish-red bituminous sand; from the borings, up to 16—32 kilos.

of crude petroleum were obtained daily. The southern deposit, consisting of what are known as the "kerosene lakes," is of a somewhat similar character, the petroleum lying below a layer of asphaltum. Of these areas covered with asphaltum, there are said to be five large ones and considerable number of smaller ones; their general location is north to south, the total length being about 100 kilometres and width about 100 m. It is stated that the climatic conditions offer no hindrance to the working of the petroleum deposits. A specimen of Saghalien crude oil examined by Bazewitsch was considered by him to be an oxidation product of a lighter oil occurring at greater depth. The fractions obtained on distillation were of higher specific gravity than those from American oil, and appeared to most nearly resemble those from Baku oil. The illuminating oils distilling over up to 100° C. (yield, at least 30 per cent.) would be quite safe even in hot climates. The author has examined the optical properties of six specimens of crude oil from Saghalien, and from the results calculated the carbonisation constants and coefficients of optical opacity (see preceding abstract).

No.	Source.	Sp. gr. at 15° C.	Carbonisation constant (K) in benzene solution.
.....	Nutowo	0.9011	per cent. 1½—1⅓
.....	Nabil	0.9364	1⅓
.....	Nogliki	0.9406	1⅓
.....	Nabil	0.9599	1⅓
.....	Nogliki	0.9502	1⅓
.....	Nabil	0.9854	1⅓

NOTE.—Nos. 1, 2, 4, and 6 were obtained from the so-called "lakes"; Nos. 3 and 5 from borings.

The Nutowo oil on distillation gave the following results:—

Fractions.	Yield, per cent.	Sp. gr. at 15° C.	Colour.
at 220°—250° C.	11.87	0.8532	light yellow
125°—175° C.	14.64	0.8607	straw yellow
175°—225° C.	24.30	0.8918	orange
225°—265° C.	12.70	0.9188	orange-red
265°—300° C.	10.77	0.9300	blood-red
300°—320° C.	9.11	0.9282	deep blood-red
Residue	16.02	0.9860	black

Paraffin wax was not found in any of the distillates. (See also this J., 1900, 1159; 1904, 55).—A. S.

viscosity of petroleum illuminating oil and an apparatus for its determination. J. Ubbelohde. *Petroleum*, 1909, 4, 861—864.

Ubbelohde's viscosimeter whilst useful for lubricating oils is not suitable for the relatively mobile illuminating oils. The author describes an apparatus for determining the viscosity of these latter, and also the viscosity of cylinder oils, etc., at high temperatures. This apparatus (see fig.) comprises a cylindrical brass vessel, A, 105 mm. in diameter, to the bottom of which is connected the outlet tube, a, 30 mm. long and 1.25 mm. inside diam. The inlet tube can be closed by the ivory rod, b. The overflow tube, c, is fixed to the outlet tube, a, the distance between the upper end of c and the lower end of a being 10 mm. The time in seconds required for 100 c.c. of petroleum oil at 20° C. to flow out through a, divided by the time required for 100 c.c. of water, gives the relative degree of viscosity. Full details of the method of calibrating the apparatus with water and for carrying out the determination are given. For determining the viscosity of cylinder oils, etc., at high temperatures, the vessel, B, is made taller and is used as an oil-bath; it is also provided with a stirrer. With this apparatus petroleum benzine had the viscosity 6.692 at 20° C., and eight specimens of petroleum illuminating oils

100 ccm. at 20° C.

gave values ranging from 1.109 to 1.801 at the same temperature. Eight specimens of cylinder oils examined at 200° C. gave values ranging from 0.98 to 4.01.—A. S.

Mineral oil industry of Batoum. Chem. Trade J., May 8, 1909. [T.R.]

ALTHOUGH an improvement in the exports of mineral oils from Batoum during the year 1908 took place, the trade was depressed. The industry is also far from being in a satisfactory condition. Prices of oil at Baku were fairly high during the year, but the wells are apparently giving signs of exhaustion. The production was about 10 per cent. short of the production of 1907, which in itself was deficient. Unless new territory is discovered it is the general opinion that the wells at Baku will only be able to continue to produce sufficient oil for home consumption. 2,026,104 cases and 2,549,450 cans of petroleum were shipped from Batoum in 1908, which together represent an actual kerosene export of 5,941,492 poods, or 21,389,364 gallons. The total quantity of kerosene exported in bulk was 17,507,204 poods, or 63,025,940 gallons, and the grand total of kerosene exports amounted to 23,448,696 poods or 84,415,304 gallons. The exports of other petroleum products, in which are included mazout, spindle oil, lubricating and engine oils, amounted to 19,801,369 poods, or 71,291,236 gallons. The total of the petroleum products that were shipped from Batoum to foreign countries during the past year was 43,250,065 poods (155,706,540 gallons), against 37,073,586 poods (133,464,912 gallons) in the year 1907, and 30,999,197 poods (111,597,409 gallons) in 1906.

The quantity of mineral oil products consumed at Batoum and by the copper mines at Dzansoul for fuel and domestic purposes in 1908 was 1,660,505 poods (5,977,800 gallons), and the stock of oil in tanks at Batoum on December 31, 1908, was 5,450,951 poods (21,443,420 gallons). The total quantity of petroleum products brought to Batoum by rail and through the pipeline from Baku in 1908 was 44,625,829 poods (159,646,806 gallons), which, with the stock remaining in storage accommodation on December 31, 1907, represented a grand total of 50,861,521 poods, or 182,095,290 gallons.

PATENTS.

Destructive distillation of coal and other carbonaceous substances: Apparatus for —. T. Parker, Coalbrookdale. Eng. Pat. 4266, Feb. 25, 1908.

Each unit of the battery of retorts consists of a number of vertical tapering tubes supported in a furnace and all

fitting into a common upper chamber which serves to collect the gas given off and for charging the tubes. The lower ends of the tubes are closed by a hinged door which is common to all the tubes of one unit. —W. H. C.

Ammonia; Process and apparatus for recovering — from gases produced in dry distillation. Act.-Ges. f. Kohlendestillation, Gelsenkirchen-Balunke, Germany. Eng. Pat. 26,027, Dec. 2, 1908. Under Int. Conv., July 10, 1908.

By means of a steam ejector the gases from the coke-ovens or retorts are drawn upwards through a spiral condenser, where tar free from water is condensed, then through two water-cooled condensers, where tar and ammoniacal liquor are condensed, and then through a tar extractor. The tar and liquor from the water-cooled condensers flow into a separator reservoir, from which the liquor overflows into another liquor reservoir, and from thence is pumped into a heater. The gases from the tar extractor pass through the steam ejector and are then forced with the steam, through an ammonia still, into which is also pumped the ammoniacal liquor, and the necessary quantity of milk of lime. The steam expels the ammonia which is carried forward by the gas into a saturator, provided with a tower packed with acid resisting material, down which a shower of sulphuric acid flows into the saturator. The ammonium sulphate is withdrawn from the saturator in the usual way and the gas passes on through the heater previously mentioned, where it parts with its heat to the liquor which is then pumped to the ammonia still. —W. H. C.

Tar; Process of separating products from —. P. C. Reilly. Fr. Pat. 395,738, Oct. 28, 1908.

THE claim is for the process of separating the so-called "free carbon" from crude tar by the method of filtration without any previous dilution. The tar is heated and forced or aspirated through a filter formed by stretching cotton or other suitable fabric over a metallic gauze support. Claim is also made for the products obtained, namely filtered tar free from solid particles especially for use in preserving timber and for the carbon residue freed from the tar oils. —W. H. C.

Bitumen; Process and apparatus for extracting — from bitumen-bearing ore. G. M. Willis, Chicago, Ill. U.S. Pats. 918,628 and 918,629, April 20, 1909.

THE ore is finely ground and taken by a water conveyor to a heating pan, where some of the sand and foreign matter is deposited. The sediment is removed from this pan by a conveyor consisting of a number of spades on an endless belt, and the bitumen is transferred to a second heating pan by a skimmer conveyor travelling at a higher speed. The floating mass in this pan is agitated either mechanically or by blowing air through it, and the sediment and bitumen are transferred as before to a third pan. This pan is inclined, and is heated to dry the thin stream of bitumen which flows through it. The dry bitumen is received in a settling tank where it is further heated to allow impurities to separate, the clear bitumene being finally drawn off. —A. T. L.

Hydrocarbons; Treatment of —. E. A. L. Rouxville, Paris. U.S. Pat. 919,248, April 20, 1909.

SEE Fr. Pat. 356,716 of 1905; this J., 1906, 83. —T. F. B.

Lubricating and anticorrosive oils; Manufacture of —. F. W. Klever, Cologne, Germany. U.S. Pat. 919,884, April 27, 1909.

Treating coal tar. Fr. Pat. 395,799. See II.

IV.—COLOURING MATTERS AND DYESTUFFS.

Indican. Part II. A. G. Perkin and F. Thomas. Chem. Soc. Proc., 1909, 25, 125—126.

WHEN indican is hydrolysed by sulphuric acid (4 c.c. in 1000 c.c. of water) at 60°, simultaneously oxidising with

air, the yield of colouring matter is but 85 per cent., due in part to the formation of brown secondary products. The latter reaction does not so readily occur when the equivalent quantity of hydrochloric acid is employed, and the yield of colouring matter (about 93.5 per cent.) is thus higher. In addition to indigotin, indirubin is also formed in some quantity under these conditions. Stronger solutions of sulphuric and hydrochloric acids at the boiling point in absence of air give respectively with indican identical brown products insoluble in alkali, from which in addition to the Indoxyl Brown previously described (this J., 1907, 1193—4, and 464), an analogous substance more sparingly soluble in alcohol (Found, N=9.65) was isolated. The action of acid in the cold for a long period (compare Schunck and Roemer, Ber., 1879, 12, 2311) has a similar effect, and Indoxyl Brown is thus formed. The brown product obtained from the less extracts of the *Indigofera* by means of acid differs from Indoxyl Brown in that it is soluble in alkali, and appears to arise from a condensation of indoxyl with other compounds derived from the plant. In view of recent discussion on the melting point of dextrososazone (Tutill, this J., 1907, 1289), the pure sugar derived from indican was converted into its acetyl derivative, and this was identical with acetyldextrose.

Indican. Part III. F. Thomas, W. P. Bloxam, and A. G. Perkin. Chem. Soc. Proc., 1909, 25, 126.

THE authors have carried out experiments on the hydrolysis of pure indican by means of indimulsin, its specific enzyme (Beyerinck, Proc. K. Akad. Wetensch. Amsterdam 1899, 1, 120; Hazewinkel, *ibid.*, 1900, 2, 512, and van Romburgh, *ibid.*, 1899, 2, 344), and on the air oxidation of the solutions of indoxyl thus produced under a variety of conditions. The results indicate that, owing to the unstable nature of indoxyl, changes occur both during the fermentation and oxidation processes which prevent the reactions from proceeding in a quantitative manner. The best yields of colouring matter were given when a small amount of acid was present during the fermentation (compare Beyerinck, *loc. cit.*), and the fermented liquor was then oxidised in the presence of a trace of ammonia.

Indoxyllic acid. A. G. Perkin. Chem. Soc. Proc., 1909, 25, 126—127.

THE examination of a sample originally consisting of commercial indoxyllic acid, which had remained unopened for some years showed that no indoxyl or indoxyllic acid was now present. The product contained:

	Per cent.
Matter soluble in alkali	32.44
Indirubin	42.37
Indigotin	17.30
Moisture	2.15
Ash	1.05
Insoluble in nitrobenzene by difference	4.19

THE oxidation appears to have arisen from the gradual admission of air, and whereas the formation of indigotin is easily accounted for, it is considered that the predominance of indirubin has arisen from the formation, in the first place, of isatin from ψ -indoxyllic acid, and its subsequent condensation with indoxyl. That portion of the matter soluble in alkali contained isatin and an acid resembling phenylglycine- α -carboxylic acid, but the major bulk consisted of an amorphous, brown product, free which was isolated a brown substance very closely resembling and possibly identical with the chief constituent of the Indigo Brown (this J., 1907, 464—465) which is present in natural indigo. The examination of two other products derived in the same manner from indoxyllic acid gave results of a similar character, and it thus appears likely that in these circumstances the changes involved are of a normal character.

Indirubin; Reduction of —. A. G. Perkin. Chem. Soc. Proc., 1909, 25, 127.

IT has been shown by Fasal (Mitt K. Tech. Gewerbe-M. Wien., 1895, 307; this J., 1896, 348) that when indirubin

is reduced by zinc dust and alkali under conditions of indigo-vat practice, the Indirubin White at first formed soon undergoes further reduction, indoxyl being thus produced, and this in the dyeing operation is converted into indigotin. A study of the reaction with a large quantity of indirubin derived from an extract of *I. sumatrana* by means of isatin has shown that under these conditions oxindole is also produced, and this, obtained in colourless needles, m. pt. 120°, was identified by means of its nitroso-compound, m. pt., 204—206°, and by oxidation with ferric chloride to isatin. The formation of indoxyl and oxindole is readily understood by reference to the following scheme :

and the behaviour of indirubin in this respect does not suggest that its presence in natural indigo can be economically advantageous. In addition to oxindole, a small quantity of a yellow basic substance resembling the di-indole of Schützenberger (Jabresb., 1877, 511), $\text{C}_{12}\text{H}_{14}\text{N}_2$, was also formed in this reaction. A quantitative study of the reduction of indirubin by this method is in progress.

PATENTS.

Vat dyestuffs; Manufacture of — O. Imray, London. From Soc. Chem. Ind. in Basle, Switzerland. Eng. Pat. 8531, April 16, 1908.

DYESTUFFS of the thioindigo group are obtained by condensing α - or β -naphthisatin or their substitution products with 3-oxy-1-thionaphthene or a homologue or substitution product thereof. These dyestuffs may also be halogenated, furnishing similar products. The condensation is effected by heating the materials together, generally in nitrobenzene solution for $1\frac{1}{2}$ —2 hours at 220°—230° C. After cooling, the mass is filtered and the solid matter washed with alcohol and dried. The condensation product of bromo- β -naphthisatin and 3-oxy-1-thionaphthene dyes cotton in an alkaline vat in grey-violet tints fast to washing, light, and chlorine. The brominated product dyes in violet-grey shades which are more violet than those obtained with the unbrominated dyestuff. The condensation product of bromo- α -naphthisatin and 3-oxy-1-thionaphthene gives fast violet shades. The product obtained by condensing the chloride of bromo- β -naphthisatin and 3-oxy-1-thionaphthene or oxythionaphthencarboxylic acid in xylene solution dyes cotton in fast violet-grey tints. α -Naphthisatin and 3-oxy-1-thionaphthene furnish a dyestuff producing violet shades and the brominated derivative dyes cotton in bright brown-violet tints. The dyestuff produced by brominating the product of condensation of β -naphthisatin and oxythionaphthene gives bright violet shades.—J. C. C.

Brominated indigos; Manufacture of — O. Imray, London. From Soc. of Chem. Ind. in Basle, Basle, Switzerland. Eng. Pat. 27,747, Dec. 21, 1908.

THE tri- and tetrabromo-indigo derivatives, prepared by treating indigo in concentrated sulphuric acid at moderate temperatures with bromine, yield dyeings which are not so fast to light and chlorine as those from the bromo-indigos prepared by brominating indigo in an indifferent solvent. The products obtained by the former method are found to be mixtures, one constituent (a sulphonic acid derivative) being soluble in dilute alkali, whereas the remainder is dissolved by organic solvents such as nitrobenzene. The nitrobenzene solution, upon cooling or concentrating, deposits crystals which appear to be identical with tetrabromo-indigo, in that the dyeings agree in respect of tint and fastness to washing, light and chlorine. The crystals which separate only on a further concentration of the mother liquor yield dyeings which are much greener in tone and are not so fast to washing.—F. M.

Carbazol; Derivatives of — and dyestuffs formed therefrom. L. Haas, Paris. Eng. Pat. 2918, Feb. 6, 1909. Under Int. Conv., May 15, 1908.

By allowing nitrosophenol or its homologues or derivatives to act on carbazole in the presence of concentrated sulphuric acid, compounds are obtained which yield blue sulphide dyestuffs when treated with alkaline polysulphides. Example: 1 kilo. of carbazol is dissolved in 10 kilos. of sulphuric acid (66° B.) and a solution of 800 grms. of nitrosophenol in 8 kilos. of sulphuric acid (66° B.) is stirred in at a temperature not exceeding 30° C. The blue liquid is poured on to ice and the precipitate is filtered off, washed, and pressed. The paste is now mixed with a very small amount of water, heated with 1—1.5 kilos. of sodium sulphide until decolorisation is complete, and then 1—1.5 kilos. of sulphur are mixed in and the mass melted, the temperature not being allowed to exceed 250° C. The product is isolated and purified in the usual way. It dyes cotton dark blue from an alkali sulphide bath and the shades produced are fast to light and chlorine.—J. C. C.

Sulphide dyestuffs; Process for preparing yellow, yellow-brown, and orange-dyeing — Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 208,805, Feb. 29, 1908. Addition to Ger. Pat. 201,834, April 23, 1907.

BENZIDINE or one of its derivatives is added to the mixture of alkyl-*m*-diamines and aromatic nitro-amino- or dinitro-compounds, or of *m*-diamines or triamines and alkyl-nitro-amines or polynitro-compounds which are melted with sulphur to produce sulphide dyestuffs according to Fr. Pat. 388,539 of 1908 (this J., 1908, 895). The dyestuffs produced are yellower in colour than those previously described.—T. F. B.

[Azo] Dyestuffs which can be developed; Process for preparing — Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 208,968, March 29, 1908.

MONONITROBENZOYLDIAMINES, obtained by the action of mononitrobenzoyl chloride on monoformyldiamines and subsequently eliminating the formyl group by means of dilute mineral acids, are diazotised and combined with 2,5,7-aminonaphtholsulphonic acid or its derivatives substituted in the amino-group. On reduction of the nitro-group of these dyestuffs, products are obtained which can be further diazotised on the fibre, and developed with phenols or amines. The shades produced vary from red to violet.—T. F. B.

Compounds containing sulphur [Diketodihydrothionaphthenes]; Manufacture of — J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 17,498, Aug. 20, 1908. Addition to Eng. Pat. 28,240, Dec. 11, 1906.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Silk; Studies on the formation of — E. Abderhalden and H. R. Dean. *Z. physiol. Chem.*, 1909, 59, 170—173.

THE authors have raised the general question as to whether the mono-amino-acids, which constitute the ultimate unit groups of the protein substances present in, or furnished to, animal organisms, are capable of being changed in nature or amount, or synthesised from simpler fractions of protein hydrolysis, as the result of the processes of vital metabolism. This question is now open to investigation owing to the accumulation of data yielded by the methods of total hydrolysis, and quantitative determination of the various amino-acids produced. The authors have selected the silk-worm as a convenient subject for study from this point of view, the composition of silk as regards its constituent mono-amino acids having been fairly completely ascertained; moreover, the worm takes no nourishment after it has begun to spin. The silk fibre is particularly characterised by the fact that it contains considerable proportions of tyrosine, glycocoll and alanine groups. The authors have first investigated whether these mono-amino-acids were also present in corresponding preponderance in the worm itself before spinning, or whether they were elaborated from other groups in the act of spinning, by a special process of metabolism. Silk-worms, ready to spin, were dried and hydrolysed, in the manner previously adopted in the case of the silk fibre (this J., 1909, 240). The results showed that the worms contained large supplies of the above amino-acids most abundant in the silk fibre; glycocoll and alanine were particularly prominent in the silk-worm protein. It does not necessarily follow that the worm contains ready-formed silk-protein in the liquid state, but merely that the silk-worm protein contains the necessary ultimate units for conversion into silk by re-arrangement under the metabolic processes carried out by the silk-glands. Further light will be thrown on the general question stated above, by a study of the nature and quantity of the mono-amino-acids present in the proteins of the mulberry leaves consumed by the worms during their active life.—J. F. B.

Silk-worm moth; The mono-amino-acids of the body of the — E. Abderhalden and W. Weichardt. *Z. physiol. Chem.*, 1909, 59, 174—176.

CONTINUING the study of the general question stated in the preceding abstract, the authors draw attention to the fact that, after the act of spinning has been completed, the worm, now a moth, undergoes very considerable morphological changes in its tissues and assumes totally different functions, without the introduction of any further nourishment. If no conversion of the ultimate mono-amino-acids into other bodies of the same order, nor any synthesis from simpler nitrogenous compounds, corresponding with this profound organic change, take place, then the mono-amino-acids obtained by the hydrolysis of the moths should be the algebraic sum of the mono-amino-acids of the worms minus those of the silkworm. This was found to be approximately the case. Compared with the worms, the yields of tyrosine, glycocoll and alanine obtained from the moths were very sensibly lower and the yields of valine and especially leucine were correspondingly higher, as were also those of the other mono-amino-acids. The authors propose to study the results similarly obtained at various stages of the development of the pupa, in order to ascertain whether the change in composition takes place suddenly or progressively.

—J. F. B.

Silk; Composition and chemical structure of various species of — H. The mono-amino-acids of Canton silk. E. Abderhalden and L. Behrend. *Z. physiol. Chem.*, 1909, 59, 236—238. (See also this J., 1909, 240.)

THE amino-acid products of the ultimate hydrolysis of the fibroin of Canton silk have been studied in the same

manner as those from New-Chwang silk. Canton silk is white and closely resembles Italian silk, but has a finer filament. On de-gumming, 480 grms. of raw silk yielded 100 grms. of silk gum. The fibroin contained 5.1 per cent. of hygroscopic moisture (dried at 100° C.) and 0.32 per cent. of ash. On hydrolysis with hydrochloric or sulphuric acid, only traces of a humic residue remained. The tyrosine was determined, as before (*loc. cit.*), after hydrolysis with 25 per cent. sulphuric acid; the other amino-acids were determined after hydrolysis with fuming hydrochloric acid. The quantities of the various mono-amino-acids obtained were as follows: Glycocoll, 37.5; alanine, 23.5; serine, 1.5; leucine, 1.5; aspartic acid, 0.75; phenylalanine, 1.6; tyrosine, 9.8; proline, 1.0; glutamic acid, nil, all calculated as per cent. of the dry ash-free fibroin substance. These numbers show a striking concordance with those obtained by Fischer and Skita for the fibroin of Italian silk.—J. F. B.

Indigo in dyed cotton; Determination of — E. Knecht. *J. Soc. Dyers and Col.*, 1909, 25, 135—137.

THE method described is based upon the well-known facts that cellulose is completely dissolved by sulphuric acid of 80 per cent. strength at a temperature of 35°—40° C., and that acid of this strength also dissolves indigotin, forming a sulphate which, when treated with water, dissociates, with separation of the whole of the indigotin as such. The method was tested by dissolving 5 grms. of cotton yarn and 0.2 gm. of pure indigotin (99.5 per cent.) in 25 c.c. of 80 per cent. sulphuric acid. The whole was slowly stirred, and maintained at a temperature of 40° C.; solution was complete in about 10 minutes. The solution was precipitated by diluting with 120 c.c. of water, and the precipitate collected in a Gooch crucible containing sand and asbestos as the filtering medium. The crucible and its contents were dried at 110°—120° C., and the indigotin then sulphonated by warming in the water-oven with a little concentrated sulphuric acid. The sulphonate was dissolved in water and titrated either with titanous chloride, or permanganate solution. Two estimations, using titanous chloride, gave (1), 0.1981 gm., (2), 0.1979 gm. of indigotin instead of 0.1990 gm. In testing a sample of dyed cloth, about 4 grms. of the material should be taken, cut up into fine pieces, and treated as described. The usual topping colours employed with Indigo (Methyl Violet, Safranine), and Sulphide Blues do not interfere with the results, but Manganese Bronze must be removed by treating with bisulphite before proceeding with the estimation of the Indigo.—F. M.

Acid Green extra; Remarkable atmospheric action on yarn dyed with — A. Herz and C. E. Barracough. *J. Soc. Dyers and Col.*, 1909, 25, 139.

WOOL yarn which had been dyed bright green with Acid Green extra (By.) and Acid Yellow G. (Berlin) and left over-night without washing off, became quite yellow wherever the atmosphere had had free access to it. Washing in boiling water restored the original colour, but the washed hanks became again yellow, after exposure to the atmosphere for about two hours. The atmosphere was acid to litmus, and it was found that gaseous sulphurous acid was capable of bringing about the change of colour the original shade being restored by washing with hot water or on heating. Acid Green extra is bleached by a cold solution of sulphurous acid; on boiling, the colour returns, but is destroyed again on cooling.—F. M.

Picric acid; Colouring and dyeing properties of — L. Vignon. *Compt. rend.*, 1909, 148, 844—846.

1. THE depth of colour of picric acid solutions in various solvents (water, alcohol, ether, benzene) varies in the same sense as the electric conductivity of the solutions.
2. Aqueous solutions dye wool and become impoverished when their conductivity reaches a certain value; this may be achieved either by increase of the quantity of picric acid dissolved, or by addition of hydrochloric acid.
3. In alcoholic solution containing 1 part of hydrochloric acid in 10,000, though the conductivity is considerable there is very little fixation of the dyestuff on the fibre. The fixation of the colour on wool seems, under the conditions employed, to be due to a chemical reaction o

the fibre on the highly ionised dyestuff. It is not due to the formation of salts; for picric acid in benzene solution does not dye wool, though it combines energetically with organic bases.—J. T. D.

Ramie incandescent mantles. Böhm. See II.

PATENTS.

Shrinking properties of wool or animal fibres, and woollen yarn and fabrics; Treatment for modifying the —. J. Schneider, Galashiels. Eng. Pat. 11,834, June 1, 1908. Addition to Eng. Pat. 6152, Mar. 14, 1907 (this J., 1908, 331).

Loose wool or animal fibres, woollen yarn, etc., treated with caustic alkali of less than 32° Tw. acquire the same properties as regards felting, as when treated with chlorine. Fabrics shrink a little under the treatment, but the loss in weight is not so great as in the case of treatment with chlorine. The immunity from shrinkage under a subsequent mild alkaline treatment (milling) is proportional to the strength of the caustic alkali (up to the limit of 32° T.) used in the first instance.—F. M.

Kiers for linen or cotton piece goods or yarns; Bleaching or boiling —. S. J. Frazer, Culleybackey, Ireland. Eng. Pat. 17,653, Aug. 22, 1908.

The kier is provided with a flexible bottom or support for bearing the material to be treated. This bottom comprises, in combination, a central ring resting on a vertical standard, a series of radiating chains secured at their outer ends to the wall of the kier and at their inner ends to the central ring, and finally a series of concentric chains which are suitably fastened to the radiating chains.—P. F. C.

Treating fabrics in spread out form with liquids; Process and apparatus for —. E. Gminder, Reutlingen, Germany. Eng. Pat. 21,829, Oct. 15, 1908.

The fabric to be treated is led through an opening in the side-wall of a cylindrical receiver which is arranged during the filling process with its axis horizontal. In order to arrange the material in regular zig-zag folds, the receiver is made to rock about an axis eccentric to its own. When full, the receiver is placed with its axis vertical, the opening in the wall is closed, and the liquor necessary for the treatment is circulated vertically through the apparatus by means of a pump.—P. F. C.

Dyeing apparatus. T. Allsop and W. W. Sibson, Assignors to The Philadelphia Dyeing Machinery Co., Philadelphia, Pa. U.S. Pat. 918,485, April 13, 1909.

A ROTATABLE perforated cylinder is arranged inside a vat which is provided with means for circulating the dye-liquor. These circulating devices are such that the liquor inside the vat can be made to flow alternately in opposite directions.—P. F. C.

Dyeing machine. C. J. McNamara, Assignor to G. Gross, Philadelphia, Pa. U.S. Pat. 918,767, Apr. 20, 1909.

The upper part of a dye-vat is provided with a movable frame, which carries a number of "dye-sticks" having earings at their ends by means of which they are rotated from a crank shaft.—P. F. C.

Dianthraquinonylamines; Process for fixing the —, obtained according to Ger. Pat. 174,699, or vegetable fibres. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 208,845, Feb. 9, 1908.

The dianthraquinonylamines obtained according to Ger. Pat. 174,699 (see this J., 1907, 314) are reduced to the succo-compounds by means of alkaline reducing agents e.g., hydrosulphites in alkaline solution, and the vegetable fibres or fabrics are immersed in this solution and the colour is subsequently developed by oxidation: very fast, clear, orange shades are produced by this means.—T. F. B.

Green, olive and brown effects in dyeing and printing; Production of —. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 14,593, July 9, 1908.

By oxidising *m*-aminophenols on the fibre with alkali chlorate and ferrocyanide, shades fast to light and washing are obtained. Example:—A bath is prepared containing 25 grms. of *m*-aminophenol, 50–60 c.c. of 30 per cent. hydrochloric acid, 60 grms. of potassium ferrocyanide, and 25 grms. of sodium chlorate in a litre. The goods are padded with the filtered solution, dried, then steamed for about ten minutes in a Mather-Platt apparatus and next treated with a lukewarm solution of sodium bichromate. To obtain a green shade, the goods are washed in acidulated water and dried. To obtain a brown shade it is necessary to pass the goods through a solution of sodium silicate and then wash and soap. If desired, a reserve can be printed on to the prepared goods immediately after drying. For a white reserve a mixture of 400 grms. of gum solution, 100 grms. of Rongalite C and 400 grms. of potassium sulphite solution (45° B.) mixed with 100 grms. of gum solution, can be employed. For coloured reserves on cotton, the ordinary albumin dyestuffs to which alkali sulphite and acetate have been added, or basic dyestuffs with zinc white, can be used. Upon silk or half-silk, it is sufficient to print basic dyestuffs together with potassium sulphite and sodium acetate.—P. F. C.

Printing of textile fabrics. F. Ashton, Hyde, and The Calico Printers' Association, Limited, Manchester. Eng. Pat. 8620, Apr. 18, 1908.

THE application of resists of resins, fats, or other substances having high melting points, by printing machines has hitherto been made difficult by the solidification of the molten resist upon the engraved rollers. To remedy this difficulty, the engraved rollers and the doctors with which they are provided, are maintained at a temperature sufficiently high to prevent solidification of the resist.—P. F. C.

Fatty acid compounds with aldehydes and ketones and the application thereof in colour printing; Manufacture of new organic —. O. Imray, London. From Farbwärke vorm. Meister, Lucius, und Brüning, Höchst a/Main, Germany. Eng. Pat. 13,790, June 29, 1908.

By treating unsaturated organic fatty acids of high molecular weight with aldehydes and ketones, new compounds are formed which are soluble in alkalis and are very stable in the cold. When heated however, they react like free fatty acids and they are therefore very useful in printing with certain alizarin dyestuffs, such as Alizarin Red and Alizarin Orange, which could hitherto only be printed on goods which had previously been prepared with Turkey-red oil or the like. By adding the above described new compounds to the printing colour, colour lakes are not formed until the goods are steamed, and the previous oiling of the material becomes unnecessary. Example 1: One kilo. of castor oil is gradually mixed with 250 grms. of formaldehyde (40 per cent.) at 20° C. and stirred for some time. Then 200 grms. of concentrated sulphuric acid are added as a condensing agent at 15°–20° C. and the mixture is allowed to stand overnight. The reaction product is stirred in a 10 per cent. solution of Glauber salt and is then heated to 90° C. The oil is next removed and well washed to free it from traces of acid. The product is finally allowed to settle and the separated water is removed. Example 2: To prepare a printing colour, 50 grms. of the product made according to Example 1 are mixed with 400 grms. of acid starch thickening, 200 grms. of tragacanth (60:1000) 75 grms. of Alizarin Red 5 F. (20 per cent.), 25 grms. of Alizarin Red 1 B (20 per cent.), 55 grms. of water, 90 grms. of aluminium thiocyanate (12° B.), 30 grms. of aluminium acetate (12° B.), 20 grms. of tin oxalate (16° B.), 15 grms. of tartaric acid solution (1:6) and 40 grms. of calcium acetate (16° B.).—P. F. C.

Discharge of colouring matters of the Thioindigo and Indigo classes, and pastes to be employed therein. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen a Rhine, Germany. Eng. Pat. 8726, April 21, 1908.

STANNOUS chloride, in an acid medium, has been proposed as a discharging agent for indigo, but is not very suitable as the fibre is attacked and tendered in the process. Thioindigo and indigo dycings may be discharged however by means of glucose (or other carbohydrate), or stannous oxide, in the presence of alkali. A suitable paste for discharging deep shades of indigo is prepared by mixing 650 parts of gum thickening with a solution of 50 parts of 50 per cent. stannous oxide paste in 100 parts of water and 200 parts of 35 per cent. caustic soda lye. The printed material is dried at a moderate temperature, steamed for 5 minutes at 100–105 C. in air-free steam, passed through boiling water containing 10 c.c. of a 35 per cent. caustic soda solution per litre, and finally washed.—F. M.

Goffing effects on yarns, tissues, or the like: Process of obtaining — C. T. Tredup, Godesberg, Germany. U.S. Pat. 918,397, April 13, 1909.

The goods are first impregnated with a bath containing a substance which can be coagulated, then condensed with rollers which are not hot enough to cause coagulation and are finally exposed to dry heat and to steam under pressure, in order to convert the impregnating substance into an insoluble coating.—P. F. C.

Waterproof and lustrous cloth or other fabric and the method and means for producing it. R. Hübner, Radcliffe, and J. H. Riley and Co., Limited, Bury. Eng. Pat. 7972, April 10, 1908.

The fabric is coated with stearic acid or a mixture containing it and is subsequently passed through a Schreiner calender. In order to apply the stearic acid, the fabric is passed between two squeezing rollers, the upper roller having an india-rubber surface whilst the lower one is made of brass and has a finely grooved surface. This lower roller revolves with its lower part immersed in molten stearic acid. A doctor may be used to remove the excess of stearic acid from the lower roller before it touches the fabric.—P. F. C.

VII.—ACIDS, ALKALIS, SALTS, AND NON-METALLIC ELEMENTS.

"Chamber regulator" [in sulphuric acid manufacture]. H. Petersen. Chem.-Zeit., 1909, 33, 409–411.

THE advantages claimed for the use of a "chamber regulator" (see this J., 1907, 870; 1908, 981) in the manufacture of sulphuric acid may be summarised as follows:—(1). More efficient fixation of the acid gases leaving the chambers is secured. For nitrous vitriol of the strength used (53°–57° B.) will absorb sulphur dioxide with the production of sulphuric acid and will also absorb oxides of nitrogen, if necessary, though, on the other hand, it will give up these oxides, if there be a temporary deficit and thus keep up the percentage in the Gay-Lussac acid. (2). Sulphuric acid is produced in the regulator itself, as above indicated. (3). Economy is effected in the consumption of nitric acid by the more regular working of the system. (4). The total production

of acid is increased, owing to the possibility of more rapid working, and this without the use of a "double ring" of Gay-Lussac and Glover towers. (5). A stronger acid may be produced in the chambers; for, any deficiency in water vapour in the last chamber, which renders complete fixation of the sulphur dioxide impossible, is made up for by the absorption of this gas in the regulator. Figures are given, relating to an English factory, which show a reduction from 7.4 grms. to 1.7 grms. of sulphur trioxide per cb. m. in the final exit gases and a decrease in the consumption of nitric acid from 1.7 per cent. to 0.7 per cent. after the introduction of a regulator, the yield of acid on the sulphur burnt also showing improvement. The size of the tower constituting the regulator varies from 0.2 per cent. of the total chamber space for systems of 6000–8000 cb. m. to 0.4–0.5 per cent. with systems below 4000 cb. m. A case is recorded of a tower of 75 cb. m. capacity which produced 2900–3000 kilos. of acid (50° B.) in 24 hours, or one-eighth of the total production of the system.—F. SOPH.

Sulphuric acid: Purification of —, from arsenic, by freezing. M. Morane. Compt. rend., 1909, 148, 842–843.

When sulphuric acid is partially frozen, any arsenic present is concentrated in the liquid portion. A sample of Glover tower acid was concentrated to 1.72 sp. gr., and exposed for a day to a temperature varying between 2 and –8 C., when half of it froze. The solid and liquid portions were separated and analysed. For every 100 parts of monohydrate, they contained respectively:—

	Solid portion.	Liquid portion.
Non-volatile residue	0.281	0.829
Ferric oxide and alumina	0.029	0.119
Arsenic	0.033	0.368

—J. T. D.

Sulphuric acid: Concentration of — in cast iron vessels. H. Friedrich. Chem.-Zeit., 1909, 33, 478–479.

A thin stream of Glover or chamber acid, from 50° to 60° B. in strength, is directed on to the surface of a large quantity of concentrated acid of 66° B., which is kept boiling inside a suitable cast iron vessel. The concentrated acid is drawn off from the bottom by means of a siphon, suitable provision being made for condensing the distillate. The cast iron vessel should last at least one year; the space required for the apparatus is 15–20 cubic metres; and a daily output of about 5000 kilos. of 93 per cent. sulphuric acid is obtained at a capital expenditure of £200–£250.—O. R.

Nitric oxide from the air: Formation of — by means of a current of electricity of low voltage. G. W. Morden. Trans. Amer. Electrochem. Soc., 1908, 14, 113–141.

THE author's work is a continuation of that of Haber and Koenig (this J., 1908, 27, 1070), who attempted, by means of a cooled arc, to obtain results due chiefly to electrical action. The apparatus used was different from that of Haber and Koenig: direct current was employed, and short arcs. The cathode was of iridium covered with calcium oxide; the fall of potential at the cathode was relatively very small, and vapour of the electrode material was not present in the arc. The current strength varied between 0.1 and 0.25 ampère with a voltage at the arc ranging from 100–280 volts. It was found that the highest concentrations of nitric oxide were obtained at pressures between 300 and 500 mm. Small gas velocities were favourable to high concentrations, and great velocities to high yields per kilowatt-hour. For every gas velocity there was a maximum concentration of nitric oxide possible; increase of current strength beyond that necessary to attain this concentration resulted only in a decrease in the yield per kilowatt-hour. By using as anode a hollow, water-cooled, silver capillary tube, and by sucking the gases out through its centre, with a hot cathode lying quite near the anode, it was possible to obtain

either high concentrations of nitric oxide or high yields per kilowatt-hour by using appropriate pressure and gas velocity. Hitherto the highest concentrations of nitric oxide obtained from air were 9.5–10 per cent. by Haber and Koenig at 100 mm. pressure. The author obtained a concentration of 9.7 per cent. at 300–400 mm. pressure and with low voltage. The yields obtained in the best commercial processes are given as 550 kilos. of nitric acid per kilowatt-year, or 63 grms. per kilowatt-hour. In the author's experiments a yield of 92 grms. of nitric acid per kilowatt-hour was attained.—A. S.

Finlay electrolytic alkali-chlorine cell; The current and energy efficiencies of the —. F. G. Donnan, J. T. Barker, and B. P. Hill. *Faraday Soc.*, April 27, 1909. [Advance proof.]

In the Finlay electrolytic cell, a middle brine chamber separates, by means of diaphragms, the anode and cathode chambers, whilst a continuous flow of electrolyte is supplied, under a "head," to the middle chamber and passes through the cell diaphragms. The various compartments are built up in the form of a filter-press, so that both sides of the electrodes are electrolytically active, and the resistance is reduced to a minimum by diminishing the thickness of the electrolyte in each compartment. The anodes are of graphite and the cathodes of wrought iron. A series of experiments have been carried out by the authors on a laboratory form of the cell, the current and rate of flow of the electrolyte being maintained constant. Very little disintegration of the carbon anodes was observed, and the particles of carbon were swept out with the anode effluent, thus avoiding the choking of the diaphragms. The cathodic current efficiency (with 2 mm. diaphragms) does not appear to improve with increase of current density, but is a function mainly of the alkali concentration, about 7 per cent. of caustic soda being obtained with an efficiency of 91 per cent. With thicker diaphragms two 2 mm. diaphragms placed together, considerably higher cathodic current efficiencies were obtained for the same strength of caustic soda, and it appears that for higher strengths the efficiency increases with the current density, whilst for lower strengths the reverse is the case. With diaphragms loaded slightly with ferric hydroxide, the average current efficiencies are about the same as those obtained with two 2 mm. diaphragms at the same current density, with the great advantage that the cell voltage is sensibly lower. The composition of the anode gas shows that it contains about 99 per cent. of chlorine, when the cell is making 6 to 7 per cent. caustic soda solution. Experiments have also been made showing that for moderate concentrations of caustic soda (6 to 8 per cent.), the Finlay cell, with double diaphragm and percolating electrolyte, gives enormously higher current efficiencies than single diaphragm cells with non-percolating electrolyte.—B. N.

Nitrogen; Determination of — in saltpetre by means of stannous chloride and iron filings. A. Kleiber. *Chem.-Zeit.*, 1909, 33, 479–480.

The reduction takes place in accordance with the equation, $\text{KNO}_3 + \text{SnCl}_2 + 10\text{HCl} + 3\text{Fe} = \text{NH}_4\text{Cl} + \text{SnCl}_4 + 3\text{FeCl}_2 + \text{KCl} + 3\text{H}_2\text{O}$. For the determination, $\frac{1}{2}$ gram. of saltpetre dissolved in 7.5 c.c. of water is introduced into a distilling flask of about 1 litre capacity, about 5 grms. of solid commercial stannous chloride, 15 c.c. of concentrated hydrochloric acid, and about 4–5 grms. of iron filings are added to the solution, and the mixture is heated on the water-bath for 10–15 minutes. 40 c.c. of saturated caustic soda solution mixed with about 100 c.c. of water and a piece of paraffin wax the size of a pea are added, and the mixture is rapidly distilled over a strong flame, so that the whole distillation is complete in under half an hour. The ammonia is preferably distilled into $\text{N}/2$ sulphuric acid and the excess of the latter titrated with $\text{N}/4$ baryta water. To make the necessary correction for the ammonia retained by the apparatus in the above instance, 0.2 c.c. must be subtracted from the volume of $\text{N}/4$ baryta water used.—O. R.

Calcium-alkali sulphates. J. D'Ans and O. Schreiner. *Z. anorg. Chem.*, 1909, 62, 129–167.

CONCENTRATION-TEMPERATURE diagrams are given of all the double sulphates known to be formed by the alkali metals with calcium between 0° and 100° C., showing their fields of existence and temperatures of formation, as far as could be determined. The salts included in the investigation are the syngenites, $\text{K}_2[(\text{NH}_4)_2\text{Rb}_2]\text{Ca}(\text{SO}_4)_2 \cdot \text{H}_2\text{O}$, the dicalcium sulphates, $(\text{NH}_4)_2[\text{Rb}_2\text{Cs}_2]\text{Ca}_2(\text{SO}_4)_4$, the pentacalcium sulphates, $\text{K}_2[(\text{NH}_4)_2]\text{Ca}_5(\text{SO}_4)_6$, and glauberite, $\text{Na}_2\text{Ca}(\text{SO}_4)_2$. The existence of a labile double salt of the formula, $\text{Na}_4\text{Ca}(\text{SO}_4)_3 \cdot 2\text{H}_2\text{O}$, has also been established, but no double salts with thallium or lithium have been obtained. The influence of various electrolytes and of sucrose on the solubility of potassium syngenite at 25° C. has been studied. Potassium salts are found to lower the sulphate concentration of the solution which is in equilibrium with syngenite and gypsum at that temperature, and the concentration of the potassium salt for which $\text{Ca}=\text{SO}_4$, and beyond which, therefore, the salt is able to form syngenite by double decomposition with gypsum, is found to be 12 mols. of potassium acetate, 18 of potassium chloride, 17.2 of potassium bromide or iodide, and 26 of potassium nitrate per 1000 mols. of water. Acids, on the other hand, increase the concentration both of sulphate and calcium, and, as a rule, their influence is in the order of their affinities; the sodium salts act like the corresponding acids, but less powerfully. The effect of electrolytes is quite analogous to that observed in studying the solubility of gypsum. Sucrose has but little influence on the concentration either of sulphate or of calcium in the equilibrium solution.—F. SONX.

Cuprous and cupric chlorides in hydrochloric acid solution; Equilibrium between —. G. Poma. *Atti R. Accad. dei Lincei*, Roma, 1909 [5], 18, I, 133–138. *Chem. Zentr.*, 1909, 1, 1386.

THE author determined the solubility of cuprous chloride in solutions containing known quantities of hydrochloric acid and cupric chloride, and also in solutions of hydrochloric acid of equal concentration free from cupric chloride. In all cases a larger quantity of cuprous chloride was dissolved by solutions containing cupric chloride. In solutions containing hydrochloric acid in concentrations of 1-N and 2-N, the ratio between this extra quantity of dissolved cuprous chloride and the amount of cupric chloride present increased with increasing concentration of the latter, but in solutions of 4-N acidity, the ratio was almost constant at 0.4. In solutions of cupric chloride in methyl alcohol, free from hydrochloric acid, the ratio was also 0.4. It is concluded that one or more complex cuprous-cupric salts are formed.—A. S.

Lead sulphate; Solubility of — in concentrated solutions of sodium and potassium acetate. J. J. Fox. *Chem. Soc. Proc.*, 1909, 25, 128.

THE increased solubility of lead sulphate in concentrated solutions of sodium and potassium acetates is due to the formation of lead acetate in solution, conclusive evidence being obtained from the examination of the system potassium acetate—lead sulphate. In this case no sulphate was dissolved, although as much as 19 per cent. of lead acetate was found in one of the solutions. As regards the system sodium acetate—lead sulphate, the proportion of sulphate in solution was equivalent to the lead dissolved. The solid phase in the potassium acetate system was altered, lead potassium sulphate, $\text{PbK}_2(\text{SO}_4)_3$, being formed, but no corresponding double salt was obtained from the sodium acetate system. The absence of double salt in the latter case probably arises from the fact that the amount of sodium sulphate formed from the lead sulphate by sodium acetate is insufficient, considered alone, to saturate the solution at 25°. The solubility curve for sodium sulphate in sodium acetate solution is entirely different in character from that of potassium sulphate in potassium acetate, the solubility in the latter case decreasing rapidly with increasing concentration of the potassium acetate. Although the solubility of lead sulphate is shown to be due to the formation of lead acetate in solution, the solubility

curves do not coincide with those derived from the system lead acetate—alkali acetate, since the presence of sulphates in the solid phases tends to reduce the solubility of the lead.

Silver and lead compounds: Impossibility of predicting thermochemically the relative stability of corresponding —. A. Colson. *Compt. rend.*, 1909, 148, 837—839.

THE heats of formation of lead carbonate and nitrate are greater than those of the corresponding silver salts. But whilst at higher temperatures lead carbonate is more stable than silver carbonate, lead nitrate begins to decompose at 283° C., silver nitrate only above 350° C. If lead nitrate be dissolved in melted silver nitrate (in which it is largely soluble with absorption of heat, and thus with diminution of its heat of formation) it gains in stability, for its temperature of initial dissociation is raised to 350° C.—J. T. D.

Bismuth trichloride: Hydrolytic dissociation of —. R. Dubrisay. *Compt. rend.*, 1909, 148, 830—832.

WHEN clear solutions of bismuth chloride in hydrochloric acid are treated with water so as just to effect precipitation of the bismuth oxychloride, equilibrium is reached after three days at the ordinary temperature, after twelve hours at 80° C. Determinations of the composition of the clear liquid remaining after equilibrium is reached, show that the system is bivalent, and hence there is but one oxychloride; and also that the dissociation of the chloride and formation of oxychloride diminish as the temperature rises.—J. T. D.

Coke: Action of —, on ferric chloride and auric chloride in solution. A. Tingle. *J. Amer. Chem. Soc.*, 1909, 31, 461—463.

THE author has repeated with coke, in a slightly modified form, some of the experiments of de Coninck (this J., 1900, 744). Solutions of auric chloride, neutral ferric chloride, and "basic ferric chloride" (the neutral solution to which sodium carbonate had been added till a permanent precipitate just began to form) containing 0.3 to 0.5 gm. of metal per 100 c.c., were allowed to percolate through 20 cm. depth of coke, which passed a 20-mesh but was retained by a 40-mesh sieve, at the rate of 5 c.c. per minute (except Expt. 7, in which the rate was 1 c.c. per minute). In one set of experiments, washed coke was used, i.e., coke which had been extracted with hydrochloric acid and washed free from acid. The results were as follows:—

Washed coke.

	Per cent. of metal lost or gained.	Per cent. of iron reduced to ferrous state.
1. Ferric chloride	— 2.40	1.56
2. Do.	— 0.72	0.50
3. Basic do.	— 7.23	2.50
4. Auric chloride	— 42.75	—

Unwashed coke.

5. Ferric chloride	+ 1.44	22.50
6. Basic do.	— 16.53	not determined
7. Do.	— 7.05	not determined
8. Auric chloride	— 73.82	—

In the author's opinion the results are due largely if not entirely to the sulphur compounds in the coke.

Determining perchlorate. Rothmund. See XXIII.

PATENTS.

Zinc compounds and ammonia [from galvanisers' skimmings]: Method of and apparatus for recovering —. E. G. and M. M. Pearlman, Philadelphia, Pa. U.S. Pats. 919,375 and 919,376, April 27, 1909.

SAL-AMMONIAC (ammonium chloride) flux or skimmings, a by-product of the galvanising process, is roasted in a furnace provided with a stack closed at the top. The

fumes evolved, containing zinc chloride and ammonia, are led off from the stack, through a side conduit, to an injector-device, where they are mixed with steam, and are then forced through tanks containing respectively milk of lime and a solution of sulphuric acid, in order to recover the zinc as hydroxide and the ammonia as ammonium sulphate.—A. S.

Carbides: [Electric] Process for producing —. R. Catani, Rome, Italy. U.S. Pat. 918,419, April 13, 1909.

THE carbon, used in the production of the carbide (e.g., calcium carbide), is coated with a refractory compound, such as slaked lime, and heated with slaked lime in an electric furnace, the electrodes of which are also coated with the same compound.—B. N.

Oxygen and hydrogen: Electrolysis of water for the production of —. K. J. Varielle. First Addition, dated Oct. 28, 1908, to Fr. Pat. 355,652, June 27, 1905 (this J., 1905, 1240).

THE troughs, described in the main patent, for the separation of the electrodes are replaced by vertical series of elements each of triangular section, and either solid or hollow. Each electrode consists of a sheet, with U-shaped pieces bound on each side with rivets. The gases are collected in bells, either stamped out of sheet metal or consisting of sheets cut out and folded, and united at the angles by autogenous soldering.—B. N.

Lime: Method and apparatus for slaking —. W. Schulthess, Paris. Eng. Pat. 19,656, Sept. 18, 1908.

SEE Fr. Pat. 390,357 of 1908; this J., 1908, 1018.—T. F. B.

Alkali chloride solutions: Apparatus for the electrolytic decomposition of — by means of mercury cathodes. J. J. Rink, Copenhagen. U.S. Pat. 918,370, April 13, 1909.

"Liquefaction" of clay by alkalis. Böttcher. See 12.

PATENTS.

Glass sheets: Method of and apparatus for making —. H. K. Hitchcock, Tarentum, Pa., Assignor to C. V. Brown, Pittsburg, Pa. U.S. Pat. 918,323, April 13, 1909.

A RECEPTACLE containing molten glass is connected to a conduit with an external basin. The walls of the conduit are constructed so that the heat dissipated from it is proportional to the quantity of glass flowing through it, so as to bring the glass in the basin to a workable temperature. Means for drawing glass sheets from the basin (a bait, rolls, etc.) are provided, as well as means for controlling the flow of glass through the channel and opening through which the basin may be drained.—A. G.

Metallic coatings; Application of — to articles of glazed china, porcelain, or earthenware. H. L. Sulman, H. F. K. Picard, and F. P. Heath, London. Eng. Pat. 7230, April 1, 1908.

A LAYER of "liquid metal" is first applied to the glazed article, and fixed by firing as usual. The article is then washed successively in hydrochloric acid, water, potassium hydroxide solution, and water, and immersed in a plating bath, from which gold, silver, or other metal is deposited electrolytically on the existing metallic film. The "liquid metals" used are "liquid gold" consisting of 80 per cent. of an oily medium, 12 of gold, 6 of sulphur, 1 of bismuth, and 1 of lime, chromium, and iron; and "liquid silver" and "liquid platinum," in which the gold in the above composition is replaced by platinum.

Electric furnace for fusing silica. Fr. Pat. 396,017. See XI4.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

[Bricks.] *Remarkable lime inclusion in —.* H. Seger and E. Cramer. Tonind-Zeit., 1909, 33, 491.

THE effects of lime inclusions on clays, after burning, depend upon the chemical composition and size of the inclusions, and also upon the temperature reached during firing. The authors have examined some bricks which had not been ruptured although they contained inclusions measuring as much as 12 mm. in diameter. The clay was yellowish-brown and contained a considerable quantity of limestone fragments. The bricks were burnt at Seger cone 010, were unaffected by immersion in water and only began to disintegrate after about 3 months. The analysis of the limestone fragments was:—Loss on ignition, 4.29; insoluble, 8.48; soluble silica, 1.10; alumina and ferric oxide, 1.12; lime, 74.78; magnesia, 1.37; potassium oxide, 0.38; and sulphuric anhydride, 8.51 per cent.

The sulphuric acid corresponds to a content of 14.40 per cent. of dehydrated gypsum. This is an important point since a high content of gypsum seems to retard the slaking of the lime.—W. C. H.

Clay; "Liquefaction" of — by alkalis. M. Böttcher. Sprechsaal, 1909, 42, 117—119, 133—135, 153—155, 168—170, 186—187, 199—201, 217—219, 233—235, 252—253.

EXPERIMENTS were made on the "liquefying" action of alkalis on clay, i.e., on the power of alkalis to render mixtures of clay and water more liquid. The clay used was a fire-clay similar to Bischof's standard clay III.; on analysis, it yielded: loss on ignition, 12.5 per cent.; silica (including sand, 8.4 per cent.) 50.4; alumina and a trace of iron oxide, 34.2; lime 1.5; magnesia 0.15; the remainder, about 1.25, being alkali. About 0.1 per cent. of an organic substance soluble in ether, and 0.012 of calcium sulphate were also present. The liquefying action of alkalis was examined in two ways: In the first place, 25 grms. of the clay were allowed to stand for 15 minutes with 32 c.c. of water containing the alkali in solution; the whole was then well mixed and its viscosity determined by noting the time required for a definite volume of the mixture to issue from a wide glass tube drawn out to an opening 2 mm. in diameter, and always filled to the same height; the mixture was then allowed to stand for 3 hours, and its viscosity again determined in the same way. Secondly, 2 c.c. of the mixture were diluted with about 20 c.c. of water in a test-tube, the whole was well shaken, allowed to stand, and examined after the lapse of several weeks to see how far the clay had settled. It was found that for each alkali tested there exists a maximum proportion of alkali to clay which gives the greatest fluidity; beyond this maximum further increase in the amount of alkali present produces decrease in the fluidity, although even then the viscosity of a mixture of clay and water alone is not reached. This maximum proportion of alkali to clay is independent of the quantity of water present, although this of course affects the absolute viscosity of the

mixture. Alkali hydroxides act 5—6 times as strongly as the corresponding carbonates; in both series the sodium compound is the most powerful, followed closely by the lithium compound, then at some distance by the potassium compound, and finally by the cesium compound. Determinations of the viscosity after 3 hours' standing showed a marked difference in the action of carbonates and hydroxides. Whereas with the former the second viscosity was always higher than the first, probably owing to a small amount of evaporation, in the case of hydroxides the second viscosity was higher than the first only up to the maximum proportion which gave the greatest fluidity at first; beyond this point the second viscosity was less than the first, so that in this series the most favourable proportion of alkali was somewhat greater than in the first series. Solutions of ammonia behaved in this respect like the carbonates of the fixed alkalis. Ammonia had also the weakest action of the alkalis examined, and an increase in its concentration after the greatest fluidity was reached, produced no change in the viscosity determined at once, and only a small one in the second viscosity. Ammonium carbonate and the bicarbonates of potassium and sodium had no action; calcium and barium hydroxides tended to stiffen clays; thus, a clay similar to the first, but containing twice as much calcium sulphate, required more alkali to render it as fluid as the first. The results obtained by the suspension of the clay mixtures in water showed that the least viscous mixtures were also those in which the clay remained suspended longest. It was also found that the clay which had settled from these suspensions was finer and occupied a smaller volume than the clay which had settled out rapidly. When more than the most favourable proportion of alkali hydroxide was present, the mixture required violent shaking to bring the clay into suspension, and this violent shaking decreased the quantity of alkali in the liquid, as shown both chemically and by an increase in the electric resistance of the liquid. The author, in agreement with Foerster (Chem. Ind., 28, No. 24), believes that the above facts are explained by the theory that clays are negatively charged colloids in contact with water, and that these colloids are dispersed and broken up by the hydroxyl ions present in an alkali hydroxide solution, and also to a lesser extent, in an alkali carbonate solution. The decrease in the second viscosity is due to the slow absorption of alkali hydroxide by the clay, thus bringing the concentration of alkali in the water nearer to the most favorable proportion. Apparently the clay does not absorb alkali carbonates or ammonia in the same way. The author's results agree well, on the whole, with those of Simonis (this J., 1905, 547) but the latter puts lithium before sodium in his series of activity.—A. G. L.

Breeze concrete; Dangers of —. D. B. Butler. J. Soc. Architects, April 22, 1909; Engineering, 1909, 87, 604.

CONCRETES made with Portland cement and samples of breeze (crushed coke, clinkers, ashes, and similar materials) from various sources were tested as to their expansion after setting. The results obtained varied widely according to the nature of the breeze used, but the chief cause of this divergence was found to be the presence of bituminous coal, there being little variation in the expansion of different breeze concretes when the breeze used was free from bituminous coal. In many cases test-pieces which expanded considerably when placed under water as soon as they were set, expanded much less when left in the air; also, many of the test-bars which had set and dried in the air, expanded considerably almost immediately when subsequently immersed in water. It was observed during the investigation that breeze concretes have a tendency to corrode iron and steel with which they come in contact.

X.—METALS AND METALLURGY.

Iron-carbon alloys; Decarburisation of —. W. H. Hatfield. Iron and Steel Inst., May, 1909. [Advance proof.]

CEMENT steel containing 1.64 per cent. of combined carbon was almost completely decarburised by annealing in hematite iron ore in the usual way, and after annealing for the same time in carbon was practically unchanged, the carbon still remaining in the combined state. It was also shown that in the case of white iron annealed in iron ore under conditions such as obtain in practice, decarburisation took place during the early stages to a considerable depth without the formation of any temper carbon, the central portions consisting of unchanged white iron. After the maximum temperature was reached, temper carbon was formed throughout the interior.

The final casting contained 0.65 per cent. of combined carbon and 1.1 per cent. of temper carbon, although it had been maintained for three days at the annealing temperature and gradually cooled. The author considers that: (1), it is not necessary that the carbon be precipitated as temper carbon before its removal; and (2), should temper carbon be produced, only that temper carbon which has recombined with the iron by diffusion can be removed. He does not accept the theory of Wiist (see this J., 1908, 450) that it is essential that temper carbon be precipitated before elimination takes place.—O. F. H.

Bessemer steels; A heat treatment study of —. A. McWilliam and E. J. Barnes. Iron and Steel Inst., May, 1909. [Advance proof.]

ENGLISH acid Bessemer steels in the form of forged or rolled 1-inch bars, and containing from 0.10 to 0.86 per cent. of carbon, and 0.56 to 1.03 per cent. of manganese, were subjected to a systematic heat treatment and were then subjected to tensile tests and to Arnold's alternating stress test, and also examined microscopically. The experiments, though done in duplicate, were so arranged that, by taking the tensile test-piece from one end, both the alternating stress test and the microscopic examination were carried out on the same bar. The test-bars were all "normalised" by being placed in a gas muffle at 750° C., raising to 950° C. and after keeping there for twenty minutes, standing them up on end to cool in air. Annealing was carried out by heating for 35 hours at 950° C. and cooling slowly in the furnace. The heat treatment consisted in first quenching, the steels being heated quickly in a Brayshaw salt bath, controlled by two pyrometers, to either 850° C., 900° C., or 950° C. for fifteen minutes and quenched in water at 15° to 20° C. Attention is called to the prevention of scaling by the molten salts, and the more efficient quenching produced. They were next tempered by heating in a lead bath to the requisite temperature, keeping there for 15 minutes and then cooling in air. Tables are given so arranged that each table either represents one heat treatment with the results of the tests of all the steels so treated, or else contains the results of the various treatments for only one steel. The results show that as the carbon content increases there is a gradual fall in the elongation and reduction of area, and an increase in the maximum stress for all treatments. Only the 0.10 per cent. of carbon steel for all treatments, and the 0.27 per cent. of carbon steel when quenched from 850° C. and tempered at 500° C. pass the standard for Arnold's alternating stress test of 300 which is a very severe one. In micro-examination all the sections showed manganese sulphide pools elongated in the direction of rolling or forging. In the normalised and annealed series the usual sequence of structure from a low to a high carbon content was seen. In the quenched and tempered series no difference could be found between those tempered at 500° C. and those at 700° C. They all show the transition product of emulsified or sorbitic pearlite. The authors find that the saturation point of a Bessemer steel containing 1 per cent. of manganese is about 0.80 per cent. of carbon, and illustrate the paper with a few micro-photographs.—A. H. C.

Mild steel; Ageing of — and the influence of nitrogen. C. E. Stromeyer. Iron and Steel Inst., May, 1909. [Advance proof.]

THIS paper is a continuation of two previous ones on the cause of the brittleness of mild steel plates which had failed in practice. (See Trans. Iron and Steel Inst., 1907, No. 1, 200, and No. 3, 86.) Additional comparative tests on the 26 different steels previously examined were made. Small test pieces about 0.4 in. square in section were planed on opposite edges, and chisel edges pressed 0.05 in. into the machined surfaces. The samples were boiled to give them the full ageing effect which had been started by the pressure of the chisel edges and they were then bent in a testing machine. Other sets were torn in a tensile testing machine with and without previous boiling. The net results of the experiments detailed in this and the previous papers, is that the usual tensile

and bending tests do not detect those treacherous steels which, after behaving well under the steelworks tests, fail in the workshops, and also that some of the qualities of mild steel do change with time, and these changes can be accelerated by heating to the temperature of boiling water. A highly important fact revealed by the chemical analyses was the detrimental effect of the presence of nitrogen. The worst steels in the series were those containing the largest percentage of nitrogen and phosphorus, and as the former had the greater influence, instead of adding the percentages together, to get the united effect, the percentages were divided by their respective molecular weights, viz. 0.14 for nitrogen and 0.31 for phosphorus, but as even then, steels rich in nitrogen did not seem to be properly placed, these results were squared. As arsenic belongs to the same group of elements, its percentages were treated in the same way. It was then found that all steels having the sum of the modified percentages of nitrogen, phosphorus, and arsenic above 0.80 were decidedly bad and treacherous. Another striking result of these investigations was that nitrogen also raises the tensile strength of steel far more markedly than carbon. The author gives the following formula for calculating the tensile strength of a steel from its chemical analysis:—

$T = 17.20 + 25 C + 10 Si + 2.5 (Mn + 1.72 S) + 39 P + 300 N$. On account of manganese sulphide being formed in the presence of an excess of manganese, as can be detected microscopically, 1.72 times the amount of sulphur present is subtracted from the manganese (this being in proportion to their atomic weights, 55/32). A table is given showing the ultimate tenacities as found by practical tests, together with values obtained by this formula, the mean differences being only 0.7 ton per sq. in. It is important to note that nitrogen appears to have a nine-fold greater effect than carbon or phosphorus in raising the tenacity, but at the same time it is responsible for the early ageing and subsequent failure of steel that, when new, could successfully pass the usual steelyard tests.—F. R.

Steels; High-tension — P. Longmuir. Iron and Steel Inst., May, 1909. [Advance proof.]

WITH a view to determining the most serviceable class of steel for high tension and endurance purposes, the author has investigated and compared the properties of various types of steel, both in the normal condition and after appropriate treatment as regards quenching, tempering, etc. The average requirements for high-tension steels being an elastic limit of 40 tons per square inch, a maximum stress of 50 tons per square inch, and an elongation of 20 per cent. on 2 inches, the author finds that steels of the chromium-vanadium type give the best all-round results. Nickel steels containing up to 5 per cent. of nickel, were found unsuitable for purposes requiring high tensile strength in association with high elongation. Nickel-chromium steels containing up to 6 per cent. of nickel and 1 per cent. of chromium, showed a considerable advance on simple nickel steels, the characteristic features being a high elastic limit and maximum stress with a fair elongation. Of the vanadium steels, those of the chromium-vanadium type, containing up to 1 per cent. of chromium and 0.2 per cent. of vanadium, were found to be the most satisfactory for the purposes under consideration, the values obtained in these cases exceeding the average requirements for high-tension steels.—W. E. F. P.

[Iron and steel] Tests for hardness, T. Turner. Iron and Steel Inst., May, 1909. [Advance proof.] (See also this J., 1909, 93.)

FOUR of the commonly used methods of measuring the hardness of metals or alloys were selected by the author for comparison:—1. Turner's sclerometer, in which a standard scratch is produced on a smooth surface by means of a suitably weighted diamond point. 2. Shore's scleroscope, in which a pointed steel cylinder, weighing about 2 grms. falls from a definite height (about 26 in.) on to the metal to be tested, the height of the rebound of the cylinder being taken as the measure of hardness. 3. Brinell's test, in which a hardened steel

ball is pressed into the surface of the metal or alloy, and the spherical area of the indentation produced by a known pressure is measured. 4. Keep's test, in which a steel drill is rotated a certain number of times under a definite pressure, the amount of penetration being automatically registered in the shape of a curve, varying from a horizontal line for a dead soft material to a vertical line for one of equal hardness to the drill. These different methods show a remarkable agreement when testing pure cast metals, but when metals or alloys have been hardened by mechanical treatment, or in the case of ordinary or special steels, hardened and tempered, the results when tested by different methods differ widely, no method being equally suitable for all descriptions of hardness, such as tensile, cutting, abrasion, and elastic hardness. Tables of comparative tests, and numerous references are given.—F. R.

Iron; The electrolytic theory of the corrosion of —, and its applications. W. H. Walker. Iron and Steel Inst., May, 1909. [Advance proof.]

EXPERIMENTAL evidence in support of the electrolytic theory of the corrosion of iron has already been advanced by the author (this J., 1907, 1051). Friend, having concluded from his own researches that the electrolytic theory is untenable, the author shows that the carbonic acid theory of corrosion is really included in the more modern electrolytic conception, and explains the results obtained by Friend upon the latter basis. The practical applications of the electrolytic theory are considered in relation to the corrosion of iron embedded in concrete, of boiler-shells and tubes, of galvanised iron, of tin-plate, and of iron covered with a protective coating of the black oxide; and plates are given in illustration of the phenomena observed during the progress of the investigation.—W. E. F. P.

Steel; Protection of — against corrosion. M. Toch. Trans. Amer. Electrochem. Soc., 1908, 14, 207—213.

ACCORDING to the author, after the lapse of six months, there is no difference in the extent of corrosion of steel which has been coated with a good protective paint and steel which has been first rendered passive by means of a chromate and then coated with a similar paint. The corrosion is greatest where two pieces of steel come in contact, and it is recommended that such places be covered with an alkaline or an electrically insulating paint.—A. S.

Nickel in steels; Comparative study of the electrolytic method, Brunck's method, and Grossmann's method of determining —. Prettner. Chem.-Zeit., 1909, 33, 396, 411—412.

FOR the determination of nickel in steels, such as nickel-steel and nickel-chrome-steel, the methods of Brunck (this J., 1908, 284) and Grossmann (this J., 1907, 718) are both to be preferred to the electrolytic method (which, though accurate, is tedious) if proper precautions be taken. Brunck's method leads to good technical results, if an hour be allowed for the reaction, but 24 hours are required for the maximum accuracy. In applying Grossmann's method to the analysis of steel, 1 gm. of the drillings is dissolved in 20 c.c. of hydrochloric acid (sp. gr. 1.12), the solution is oxidised with 6—7 c.c. of nitric acid (sp. gr. 1.20), evaporated to 15 c.c., and allowed to cool. Then 40 c.c. of a 50 per cent. solution of Rochelle salt are added, with stirring, followed by 8—12 c.c. of strong ammonia to dissolve the precipitated tartaric acid and render the solution alkaline. 10 c.c. of an 80 per cent. solution of potassium hydroxide are next added, which should cause the solution to assume a light green colour, then about 0.3 gm. of hydrazine sulphate, to prevent interference from the small quantity of manganese present, and 1—1.5 gm. of dicyandiamine sulphate. After 24 or 48 hours, the precipitated nickel compound is collected in a Gooch crucible, washed (not more than 5 times) with weak ammonia, and dried for 30—45 minutes at 120°—140° C.; it contains 22.5 per cent. of nickel. The volumetric method of determining nickel with potassium cyanide appears, however, to be superior to either of the above, especially as regards speed, and it may be applied

directly to the analysis of steels, without preliminary separation of the nickel. The methods of Brunck and Grossmann are regarded as indispensable, therefore, only in the analysis of substances containing much cobalt.

—F. SODN.

Copper-aluminium alloys: Electrical properties (thermo-electricity and resistance) of —. H. Pêcheux. *Compt. rend.*, 1909, 148, 1041–1042. (See this J., 1909, 369.)

Thermo-electric properties.—The following values for the thermo-electric powers (in microvolts) of couples consisting of copper-aluminium alloys and copper were obtained.

	$\frac{dE}{dt}$
Cupro-aluminium-copper—	
3 per cent. of aluminium	2.31 + 0.003007
5 " " "	2.53 + 0.003207
6 " " "	1.78 + 0.000407
7.5 " " "	1.59 + 0.000907
10 " " "	1.21 + 0.001047
94 " " "	2.21 + 0.006807

Resistance.—The resistance increases with the aluminium-content until the proportion of this metal becomes 7.5 per cent., and then decreases; the resistance of the alloy containing 94 per cent. of aluminium is nearly the same as that of aluminium itself. With increase of the aluminium-content up to 10 per cent., the principal temperature co-efficient decreases; in the case of the alloy containing 94 per cent. of aluminium, this coefficient approximates to that of aluminium itself. Addition of small quantities of aluminium to copper, increases the resistance of the copper very appreciably, whereas the resistance of aluminium is hardly affected by addition of small quantities of copper.—L. E.

Silicon-calcium alloys. S. Tamaru. *Z. anorg. Chem.*, 1909, 62, 81–88.

THE alloys of silicon and calcium have been investigated by the method of thermal analysis. Molten silicon is miscible with molten calcium in all proportions, but solid silicon is insoluble in molten calcium at 900° C. From the molten alloys containing 100–35 per cent. of silicon, pure silicon separates, and this, on cooling to 990° C., combines with the melt, containing about 35 per cent. of silicon, to form the compound, CaSi_2 (58.3 per cent. of silicon); no evidence of the existence of other compounds has been obtained. The alloys with 91–60 per cent. of silicon are unaffected by water, but those with 52–38 per cent. react more or less readily, hydrogen being evolved. None of the alloys are acted upon by alkali solutions, but dilute acids attack them, with the evolution of hydrogen and silicon hydride, the action being most vigorous when a large proportion of calcium is present.—F. SODN.

Fluxes for soldering: Chemistry of —. V. Samter. *Z. angew. Chemie*, 1909, 22, 729–731.

SHEETS of electrolytic copper foil, having a surface of 100 sq. cm. on each side, were submitted to the action of solutions of hydrochloric acid, zinc chloride, and ammonium chloride respectively, and the loss of weight determined. In a 12 per cent. hydrochloric acid solution the loss was 0.25 mgrm. per sq. cm. in 24 hours, in a 25 per cent. solution of zinc chloride the corresponding loss was 0.033 mgrm., and in a 17 per cent. solution of ammonium chloride, 0.225 mgrm. In each case the rate of solution was 10 times as great when air was blown through the liquid, and it was also greater if the copper was coated with a thin layer of acid. The low solubility in hydrochloric acid is due to the formation of a protective coating of insoluble cuprous chloride. Commercial zinc chloride is always a neutral or basic salt, but strong solutions have an acid reaction owing to hydrolytic dissociation. The concentration of the free acid, however, cannot be greater than that of a 0.0036 per cent. solution of the acid, and the action on copper is accordingly very slight. The much greater action of ammonium chloride is due, not to the presence of a larger proportion of free acid in the solu-

tion, but to the fact that the concentration of the copper ions in the solution is diminished by the formation of complex ions containing copper and ammonia, and that a soluble double salt is formed from the cuprous chloride.

—A. T. L.

Zirconium: Analytical examination of metallic —. E. Wedekind and S. J. Lewis. *Z. angew. Chem.*, 1909, 22, 725–729.

FOUR samples of metallic zirconium gave the following results on analysis:—

	A.	B.	C.	D.
Metallic zirconium	83.85	73.70	63.01	24.79
Combined zirconium ..	11.70	17.49	25.41	53.68
Total zirconium	95.55	91.19	88.42	78.47
Oxygen	4.14	6.17	8.97	18.95
Nitrogen	—	2.02	1.55	—
Carbon	—	0.074	—	—
Magnesium	—	0.28	—	—

Samples A and B were commercial specimens prepared by reduction with magnesium; samples C and D were prepared by the authors by the action of potassium on the double fluoride of potassium and zirconium. All the samples had been fused. Metallic zirconium was converted into tetrachloride, by heating the powdered metal in a current of dry chlorine, free from oxygen, oxides of chlorine, nitrogen, and carbon dioxide, preferably prepared from potassium permanganate and hydrochloric acid (see this J., 1909, 424). Zirconium nitride was decomposed by the chlorine, and a correction was made for this after the determination of the nitrogen. In carrying out the analysis about 0.5 gm. of the metal was placed in a boat in a combustion tube, dried by heating in a current of hydrogen, and weighed for the determination of moisture. The air in the other parts of the apparatus was then displaced by chlorine, and a flask on the outlet of the apparatus was filled with chlorine in case of a backflow occurring during the experiment, owing to the rapid absorption of chlorine by the metal. All air having been displaced, chlorine was passed through the combustion tube, and the boat was heated gradually, finally to a dull red heat. Zirconium tetrachloride was deposited on the cooler parts of the combustion tube, any traces carried over with chlorine being trapped by bubbling the gas through 10 per cent. hydrochloric acid in a U-tube cooled in ice. The combustion tube must be quite cold before the current of chlorine is started, as, even at 40° or 60° C., amorphous zirconium may cause the explosion of a mixture of hydrogen and chlorine. After cooling, the boat, containing zirconium oxide, was weighed, and the zirconium tetrachloride was washed out of the combustion tube with cold water, the zirconium was precipitated as hydroxide with strong ammonia in the presence of ammonium chloride, and was weighed as zirconium dioxide. For the other determinations, amorphous zirconium was best dried by heating to 200°–220° C. in a high vacuum. The nitrogen was determined as ammonia, by gently heating the zirconium with strong sulphuric acid for 2 or 3 days, neutralising the acid, and distilling the ammonia into standard acid. Strong heating with the acid led to a very violent reaction, but it was found feasible to hasten the solution of the zirconium by the addition of a persulphate or other oxidising agent, provided the temperature were not allowed to rise too high. Carbon and hydrogen were determined by burning the metal in oxygen under reduced pressure. This was effected by pumping out the air from the combustion tube and also a bulb of 200 c.c. capacity connected to it, heating the boat until combustion commenced, and then admitting oxygen very gradually through a stop-cock.—A. T. L.

Action of coke on ferric and auric chloride solutions. Tingle. See VII.

Separating antimony from thioantimonate solution. Schulte. See XXIII.

PATENTS.

Annealing metals; Method of — F. J. Clinch-Jones, Leamington Spa, Warwick. Eng. Pat. 5244, Mar. 9, 1908.

THE articles to be annealed are heated in a muffle in a current of hot combustible but unignited gas (e.g., gas from a producer), which, after playing over the articles, is fired in a combustion-chamber placed below the muffle. The latter is provided at one end with a vertical channel terminating a little above the ground. Sand is delivered to the top of this channel from a hopper placed outside the muffle. The articles in the muffle are pushed over on to the sand, and descend with the latter through the vertical channel cooling gradually in doing so.—A. G. L.

Roasting furnace; Rotary — J. R. Down and F. J. Morgan, Swansea. Eng. Pat. 12,825, June 16, 1908.

THE hearth of a rotary roasting furnace is divided into two or more concentric chambers by means of one or several fixed "circular baffles" supported from the roof. The charge is introduced into the innermost chamber from a hopper, and is there roasted gently before being subjected to contact with the flames in the outer chamber.—A. G. L.

Roasting furnace. J. E. Greenawalt, Denver, Colo. U.S. Pat. 919,000, April 20, 1909.

THE ore in its passage through the furnace is supported on a porous filter or mass disposed between the hearth and the line of travel of the lowest point of the rables. Below the porous mass is a chamber to which air or other gases are supplied, these gases passing through the porous material to the charge of ore. A conduit is provided through which the porous material may be replaced or removed.—A. S.

Furnace for roasting ores. H. Daniel and H. Römer. Ger. Pat. 208,354, Nov. 1, 1907.

THE furnace consists of a shaft in which, above the fire-place, a series of superposed rotating conical drums is mounted, the axes of the drums being parallel. The larger end of each drum is connected by a conduit with the smaller end of the next lower drum. The ore (pyrites, zinc ores, etc.), is fed into the smaller end of the uppermost drum, and gradually descends, being discharged from the larger end of the lowermost one. The rate at which the ore travels through the furnace depends upon the speed at which the drums are rotated.—A. S.

Furnaces; Regenerative reversing (open-hearth) — U.S. Pats. 919,184—919,189, April 20, 1909. (2), (3), (4), and (6), L. L. Knox, Ben Avon, Pa., (1), and (5), L. L. Knox, Ben Avon, Pa., and M. Murray, Wilkesburg, Pa., Assignors to Keystone Furnace Construction Co., Pittsburg, Pa.

THE claims relate to means for cooling the walls and partitions of regenerative reversing furnaces by the circulation of water through cooling boxes arranged at certain points therein. The gas and air ports may be separated by a removable arch, this arch comprising hollow metallic side and transverse members through which water can be circulated, the whole being supported on brickwork. Or again, a number of water-cooled boxes or castings may be built permanently into the walls on the tapping or charging sides so as to extend in parallel lines along the whole length of the furnace. Finally the cooling boxes may be arranged so as to fit into narrow vertical openings in the walls or roof of the furnace, from which they can be removed when necessary. These boxes, extending entirely through the walls, present their narrow vertical inner ends to the furnace chamber at right angles to the direction of the outflowing gases. Means are provided for shutting off the water supply from one or more compartments as required.—C. A. W.

Furnace-flue dust; Method of utilising — T. M. Phillips, Assignor to the Youngstown Steel Co. and E. L. Ford, Youngstown, Ohio. U.S. Pat. 919,073, April 20, 1909.

CLAY is treated with water and steam so as to form a cream or liquid paste (see U.S. Pat. 919,074, page 511),

then blast-furnace flue dust is added, and the mass is introduced into a furnace in a fluid or "sloppy" condition.—A. S.

Tungsten; Process for increasing the ductility of — Siemens und Halske A.-G., Berlin. Eng. Pat. 17,350, Aug. 18, 1908. Under Int. Conv., Sept. 14, 1907.

SEE Fr. Pat. 393,595 of 1908; this J., 1909, 149. Less than 8 per cent. of nickel is added to the tungsten.—T. F. B.

Plumbiferous copper matte, ore, or alloy; Process for eliminating lead and other impurities, such as arsenic and antimony, from a—, and simultaneously recovering the copper as metal. Usine de Désargentation Soc. Anon., Hoboken-lez-Anvers, Belgium. Eng. Pat. 19,585, Sept. 17, 1908. Under Int. Conv., May 6, 1908.

THE impure copper matte is mixed with sufficient silica to combine with the lead present, and then partly oxidised and sintered by treatment with air or oxygen in a converter. The oxidised matte is then smelted as usual in a reverberatory furnace, metallic copper being obtained by the interaction of the copper oxide and sulphide, the lead going into the slag as silicate. If arsenic or antimony are present, a purer copper is obtained by smelting a mixture containing an excess of copper oxide over sulphide. The lead-copper-arsenic alloy obtained in lead blast-furnaces may be treated by the above process, after mixing it with copper matte or sulphide ores.—A. G. L.

Manganese steel; Working — to produce finished shapes. W. S. Potter, Mahwah, New Jersey, U.S.A. Eng. Pat. 24,685, Nov. 17, 1908.

THE ingot to be worked is heated slowly to above 430° C.; if it is tough and free from strains, it may be heated more rapidly. It is next heated rapidly to the "upper critical point," at about 1010°—1050° C., at which the metal becomes weak and tender, and is then raised carefully to the temperature at which it is to be worked. This temperature is usually about 1250° C., but for thin ingots which do not require much working, it may be 1100°—1150° C. Working is not commenced until the temperature of the skin of the ingot has fallen to that of the interior, and the pressure applied at first should be gentle. The heating may have to be repeated at intervals during the working if the ingot cools too much. It is claimed that the resulting articles have an extremely fine and uniform crystalline structure and an unbroken outer surface.—A. G. L.

Iron and steel; Metallurgy of — W. S. Simpson and H. Oviatt, London, England. U.S. Pats. 918,381 and 918,382, April 13, 1909.

IRON or steel is obtained by mixing a finely-ground iron ore with a carbohydrate containing water and another carbonaceous material, e.g., graphite, and heating the mixture. Manganese dioxide and fluxes may be added.—A. G. L.

Smelter-gases; Process of purifying — P. Danckwardt, Denver, Colo. U.S. Pat. 918,424, April 13, 1909.

A PORTION of the smelter-gases is mixed with steam and passed over red-hot carbon, whereby the sulphur dioxide of the gases is reduced to hydrogen sulphide and the carbon dioxide to carbon monoxide. The reduced gases are then mixed with a further quantity of crude smelter gases, and treated with an aqueous solution of a metallic salt which does not react with the gases, elemental sulphur being deposited owing to the interaction of sulphur dioxide and hydrogen sulphide. The gases are then brought into contact with an iron salt, which removes any excess of hydrogen sulphide and nitrogenous compounds.—A. G. L.

Zinc ores; Process of smelting — A. G. Betts, Troy, N.Y. U.S. Pat. 918,648, April 20, 1909.

THE ore is first mixed with a reducing agent, such as silicon, which is not oxidisable in air below a temperature of 800° C. The mixture is heated to a temperature

lower than this, and exposed to the furnace gases in order to bring about the oxidation of the ore, and it is then heated in a second furnace, away from the furnace gases, to a higher temperature so as to bring about the reduction of the ore by the silicon.—B. N.

Silver; Process of extracting — from its ores. J. C. Pryor, North Bay, Ontario. U.S. Pat. 918,908, April 20, 1909.

An ore containing silver together with arsenides of base metals is smelted to form a speiss, the crushed speiss is calcined, and the product is treated with suitable reagents to reduce the metallic oxides to metals, which are then extracted by a suitable solvent. The residue is subjected to a similar process.—A. S.

Metal from ore; Process of extracting —. C. G. Collins, Woodmere, N.Y. Assignor to C. A. Stevens, New York. U.S. Pat. 919,129, April 20, 1909.

The finely pulverised ore is mixed with carbonaceous material and with carbonates of the alkalis or alkaline-earths, and the whole mixture, in a state of fine division, subjected to heat in a closed retort, the resulting metal being discharged into water. If limestone be employed, a certain amount of water is added before heating, for the purpose of slaking the quicklime produced.—C. A. W.

Copper; Process of extracting — from ores. C. G. Collins, Woodmere, N.Y. Assignor to C. A. Stevens, New York. U.S. Pat. 919,130, April 20, 1909.

The finely powdered copper ore is mixed with carbonaceous material and with alkali or alkaline-earth carbonates, all in a state of fine division. The whole is heated in a closed retort and the resulting copper discharged into water. If necessary, certain proportions of hypochlorites of the alkalis or alkaline-earths may be added to the mixture before heating.—C. A. W.

Beryllium; Process for obtaining metallic — by reduction of beryllium oxide with aluminium. G. Just and M. Mayer. Ger. Pat. 208,402, June 13, 1907.

Is the reduction of beryllium oxide with aluminium by the usual thermite process, the resulting metal is spongy, owing to the relatively low heat of reaction and the high melting point of beryllium (above 1400° C.). According to the present patent, heat is applied to the reaction-mixture as usual to start the reaction, and is then increased until the melting point of beryllium is attained.—A. S.

Slimes or ore pulp; Separation of the liquid and solid components of wet —. H. G. Nichols, Ymir, British Columbia. Eng. Pat. 2479, Feb. 4, 1908.

PATENTS.

Furnaces; Electric —. C. E. Knowles, Glossop, Derby. Eng. Pat. 13,502, June 25, 1908.

A crucible is supported on a rotating stand or pillar, passing through the bottom of the furnace chamber, and is heated by at least two electric arcs produced between two adjacent or opposite pairs of carbons, the latter being connected in parallel or series circuits. Removable side blocks or walls may be used for lining the furnace chamber.—B. N.

Induction furnace; New form of electric —. Soc. des Procédés Gin pour la Métallurgie Electrique. First Addition, dated Oct. 19, 1908, to Fr. Pat. 363,937, March 7, 1906 (this J., 1906, 892).

Two vessels, containing the material to be treated, are connected together by inclined tubes, so as to form a circulatory system, and around one tube is placed a primary and secondary winding, the latter being connected to two electrodes, which are brought to the surface of the material in one of the vessels. There is thus a superficial heating effect in this vessel, in addition to the heating effect produced by the material itself forming a secondary circuit. A pair of electrodes, connected in series or in parallel, may be placed in each vessel.—B. N.

Furnace; Electric — with self-circulation. G. H. Gin. Fr. Pat. 395,460, Oct. 19, 1908. Under Int. Conv., May 21, 1908.

Two crucibles are connected by tubes, each connecting the lower part of one crucible with the upper portion of the other. Each crucible is provided with an electrode, so that there is a complete circuit from one terminal to the other through the material in the crucibles and tubes. There is thus a superficial heating in each of the crucibles, and a heating effect in each of the inclined tubes, whereby there is produced a circulation of the material from one crucible to the other. A tri-phase current may be used, by employing three crucibles, placed at the corners of a triangle, and connected in series by inclined tubes, the crucibles being each provided with an electrode.—B. N.

Furnace; Electric — for the fusion of refractory materials especially silica, and process of moulding. L. Clerc and A. Minet. Fr. Pat. 396,017, Nov. 6, 1908.

The arcs for melting the material are of great length and intensity, and are produced between carbon electrodes enclosed in carbon tubes, the internal diameter of the latter being slightly greater than the external diameter of the electrodes. The tubes, at their extremities, are connected to the carbon lining of the furnace chamber. A piston, of refractory material, may be depressed through the cover of the chamber, and thus force out the molten material through a side tube into a chamber, from which it may be emptied by mechanical or gaseous pressure or the chamber may be emptied by aspiration, as by producing a vacuum in the moulds. A refractory lining may be produced in the latter, "by making them slightly larger than the material to be moulded, and casting a refractory paste between the inner surface, and a mould

of a female form which is afterwards withdrawn." The mould may also be constructed of carbon, carborundum, or other refractory material, with a trellis-like support of chrome iron, etc., this being plunged into the melted material, or the latter may be moulded by stamping when the mass has attained a viscous state.—B. N.

Storage-battery plates; Process of making —. W. Morrison, Assignor to Exmoor Storage Battery Co., Chicago, Ill. U.S. Pat. 917,787, April 13, 1909.

The active material is prepared in the form of a paste, by mixing a suitable quantity of "soft lead" and an oxide of lead with a liquid, the latter being prepared from water, acetone, ammonium sulphate, and acetic acid.—B. N.

Cell; Electrolytic —. J. H. Reid, Newark, N.J. U.S. Pat. 917,795, April 13, 1909.

The vessel forming the cell, together with the electrodes connected to it, is mounted so that it may be rotated, and a central, hollow, perforated electrode is rotated in the opposite direction. The electrolyte is circulated through the hollow electrode to the outer electrodes, and overflows through outlet ports into a fixed tank, from which it may be again delivered to the central electrode.—B. N.

Electrolytic process. A. G. Betts, Troy, N.Y. U.S. Pat. 918,650, April 20, 1909.

A SOLUTION, containing an oxidisable substance from which a reducible compound may be produced, is electrolysed in solution, employing a suitable anode and a metallic cathode which oxidises superficially forming a coating of an insoluble hydroxide, the latter being a non-conductor of electricity and non-reducible by the electrolysis of the solution.—B. N.

Nitrogen oxides; Process and apparatus for the production of — by means of a rotating electric arc. I. Moscicki, Fr. Pat. 395,424, Oct. 17, 1908. Under Int. Conv., Oct. 17, 1907.

By means of the poles, *c* and *d*, of an electro-magnet excited by the windings, *e*, a rotating arc is produced between the electrode, *a*, and the perforated electrode, *b*, these being cooled by water entering at *f* and *o* respectively, and leaving at *g* and *p*. The gases to be treated enter under pressure at *i*, the current of gas being deflected by the edge, *r*, towards the centre of the arc. In order to avoid short-circuits of the current between the two electrodes, a cooled current of inert gas enters through the channel, *b*, spreading into the form of a cone, so that the arc forms a mantle above it, thus increasing the resistance of the central part of the space situated between the two electrodes.—B. N.

Insulating coatings on heat-resistant materials [electric cables, etc.]; Process for producing —. K. Winkler, Ger. Pat. 208,753, Nov. 19, 1907.

THE material is coated with a mixture prepared from animal fats, especially fish oils and liquid waxes, together with distillation products of rosin, and driers, and is then suddenly heated to a high temperature. For example, 50 parts of cod-liver oil, 45 parts of pinoline, and 5 parts of manganese resin are heated to 275° C., then cooled, and the alternate heating and cooling repeated until the

mass is of the consistence of honey. The product is then applied at 150° C. to the previously warmed material to be coated, and the coated material immediately subjected to a temperature of 450° C. and maintained thereat until the coating material has set. It is stated that the insulating coating thus obtained is transparent and elastic, withstands temperatures of 600° C. and upwards, and is not affected by acids, alkalis, hydrocarbons, or atmospheric influences. The product may be used in the manufacture of electric cables, as a heat non-conducting material, for making tight joints in gas- and water-mains, etc.

(B.)—ELECTRO-METALLURGY.

Lead-refining; Present-day practice of electrolytic —. A. G. Betts. Metallurgie, 1909, 6, 233–235.

ELECTROLYTIC lead-refining is carried out at Trail, B.C., near Chicago, U.S.A., and at Newcastle-on-Tyne. The first two works have a daily capacity of about 72 metric tons each; the output of the last is less. Electrolysis is carried out in a solution containing 8 grms. of lead and 15–16 grms. "SiF₆" per 100 c.c.; after it has been in use for some time, the solution also contains 0.2–0.3 per cent. of free hydrofluoric acid. In addition, 400–500 grms. of gelatin are used for every ton of lead

deposited. Electrolysis is carried out at 30–35 C. (without external heating), with an E.M.F. of 0.32 volt, and a current of 3500–5500 amperes; the current efficiency is 0.85–0.90. Each bath contains 22–28 anodes (lead plates, 920 × 610 × 25 mm.) and 23–29 cathodes. The cathodes remain in the bath 4–5 days, the anodes twice as long; hence a double set of cathodes is necessary. The electrolyte is circulated from vat to vat, avoiding exposure to the air as far as possible. The 33 per cent. hydrofluosilicic acid used in preparing the electrolyte is made by the works themselves at a cost of about 1½d. per kilo. A large part (one-quarter to one-third) of the anodes is converted into anode sludge, which is periodically brushed off the anodes, collected, freed from electrolyte first by filter-pressing and then by systematic washing, dried and partly oxidised in hot flue-gases, and then treated in a reverberatory furnace, a very easily fusible antimonial lead oxide being obtained, besides metallic lead containing the precious metals and any bismuth, and an argentiferous copper slag. The great bulk of the arsenic present is volatilised. The vats used for the electrolysis consist at present of wood coated on the inside with asphaltum; in future, cement vats will be used. The cost of the electrolytic process is about 17s. 6d. per metric ton of lead, exclusive of laboratory and overhead charges. Its chief advantage is its small loss in lead (about 0.25 per cent.) and larger recovery of the other metals present. It can also be worked economically on a small scale.—A. G. L.

PATENTS.

Metals; Depositing — upon metallic surfaces. A. Rosenberg, London. Eng. Pat. 7227, April 1, 1908.

THE metal is deposited by the frictional application, in the presence of moisture, of a mixture of pulverulent materials, the essential active ingredients of which consist of the metal to be deposited, either in the elementary form or a combined state, an electropositive metal, partly or wholly in the elementary form, such as zinc dust or magnesium powder, and a substance capable of yielding an aqueous electrolyte with the moisture. In order to prevent chemical action taking place in the mixture until required for use, soapstone ("taleum") and chalk are mixed with the dry substances to prevent the absorption of atmospheric moisture. The electropositive metal is protected against oxidation or other premature chemical action, by immersing it in a solution of paraffin, resin, naphthalene, etc., dissolved in a suitable volatile solvent, so as to give it a thin protective coating, which is readily removed by the friction employed in the depositing operation.—B. N.

Electrolytic metallic coating; Process for providing objects of non-conducting material with an —. E. A. Gerbing. Fr. Pat. 396,154, Nov. 10, 1908.

THE object is first coated with a mixture of alkali silicate solution, and a conducting material, such as graphite, carbon, or metal, in a finely-divided form, and the metal is afterwards deposited electrolytically upon the coating.—B. N.

Metals [electrolytically]; Recovering —. W. O. Snelling. Pittsburg, Pa. U.S. Pat. 917,176, April 6, 1909.

METALS, such as tin, are recovered from their electrically-conductive compounds, such as oxide ores, by making the compounds the cathode in a suitable electrolytic bath, the reduced metal being afterwards connected as the anode in the bath, in order to dissolve and re-deposit the metal.—B. N.

Metals [electrolytically]; Producing —. H. S. Blackmore, Mount Vernon, N.Y. U.S. Pat. 918,269, April 13, 1909.

THE process consists in electrolysing a molten bath containing a metallic oxide, and a salt, the anion of which will combine with the metal of the anode, the latter consisting of calcium carbide.—B. N.

Metal; [Electrolytic] Process of reducing —. H. S. Blackmore, Mount Vernon, N.Y. U.S. Pat. 918,950, April 20, 1909.

A SUBSTANCE, containing the metal in combination with one or more non-metallic elements (e.g. oxygen and a halogen), is subjected to electrolysis with the use of electrodes containing a "metal acetylide," the latter being decomposed by an ingredient of the substance employed, and thereby liberating the metal.—B. N.

Slime; Treating anode — from the electrolytic refining of lead. A. G. Betts, Troy, N.Y. U.S. Pat. 918,647, April 20, 1909.

THE slime, which is obtained from the electrolytic refining of lead containing antimony and copper, is treated with lead peroxide, a solution containing the "thorium ion," and a considerable amount of an acid forming a readily soluble salt of lead. The acid employed is the same as that contained in the electrolyte for refining the lead, from which the slime is obtained. Antimony is deposited electrolytically from the solution which is obtained, using an insoluble anode and a suitable cathode.—B. N.

Acid-proof tank for the electrolytic refining of metals. A. G. Betts, Troy, N.Y. U.S. Pat. 918,649, April 20, 1909.

THE tank is composed of porous inorganic material, such as concrete or cement, with solidified sulphur in the pores of the inner surface layer, and with an interior lining of sulphur.—B. N.

Furnace; Electric [metallurgical] —. J. H. Reid, Newark, N.J. U.S. Pat. 917,796, April 13, 1909.

THE furnace includes an outer casing, with an inner chamber, open at the top, provided with a number of horizontally extending and converging electrodes of different polarity, which, together with resistance elements, form a table covering the inner chamber. The electrodes have perforations through which the melted metal may pass, the ore being spread on and cleaned off the electrodes by means of a "sweep."—B. N.

Furnace; Electric smelting —. H. C. Harrison, Exton, Pa. U.S. Pat. 919,165, April 20, 1909.

THE furnace is of the arc type, rectangular in shape, and adapted to the use of polyphase currents. It is first charged with material relatively high in metal, until a molten bath is formed, the latter making electrical connection with the metal bottom of the furnace, which is connected to the ground. The furnace is then charged with a material of lower conductivity than the first charge. Three electrode packets, each of an oblong rectangular shape and placed in a row, are vertically disposed in the furnace, each electrode being connected to one of the branches of the star connection of a polyphase generator, the latter being also connected with the ground. Resisting charge material is placed between the electrodes, in order to prevent any substantial leakage of current from one electrode to another.—B. N.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

Linolenic acid in linseed oil; Investigation of —. E. Erdmann and F. Belford. Ber., 1909, 42, 1324–1333.

A PARTIAL separation of oleic acid from the more unsaturated fatty acids of linseed oil was effected by Farnsteiner's method of treating their barium salts with a mixture of benzene and alcohol (this J., 1899, 500; 1903, 371). The fatty acids from the soluble salts were converted

by boiling with sulphuric acid and ethyl alcohol into ethyl esters. These appeared as a colourless liquid which distilled at 133° C. under a pressure of 75 mm., and had a sp. gr. of 0.8854 at 20°/4° C. When reduced by a modification of the method of Sabatier and Senderens (Ann. Chim. Phys., 1905, 4, 319) by being passed in the form of vapour together with hydrogen over finely-divided freshly-reduced nickel, they yielded the corresponding ester of stearic acid. Reduction of linolenic acid or of the mixed unsaturated fatty acids by the same method also yielded stearic acid. From the mean hydrogen value (1.4561) found in this way, these more unsaturated esters apparently consisted of a mixture of the esters of linolic and linolenic acids containing 22.3 per cent. of the latter. This corresponded fairly well with the yield of 15.3 per cent. of linolenic hexabromide obtained from the mixed fatty acids of the oil. The authors term the acid which yields the hexabromide, α -linolenic acid. The ethyl ester of hexabromostearic acid melted at 151.5°—152.5° C., and the methyl ester at 157°—158° C. Reduction of the hexabromide with zinc and alcoholic hydrochloric acid yielded a colourless oil distilling at 157°—158° C. under a pressure of 75 mm. The ethyl ester, debrominated in the same way, had a sp. gr. of 0.8919 at 20°/4° C.; a refractive index of n_D^{20} = 1.46753; and a molecular weight of 278.9 (theory requiring 304). As was shown by Hehner and Mitchell (this J., 1899, 77) linolenic acid, reduced from the hexabromide, only yields a small amount of hexabromide when again brominated. Elementary analysis and its hydrogen value, however, show that it has the formula, $C_{18}H_{30}O_2$, although absorbing less bromine than the original linolenic acid. The authors' explanation of this is that the linolenic acid obtained by reduction of the hexabromide is a mixture of two isomeric acids. One of these is identical with the α -linolenic acid of the original linseed oil fatty acids, whilst the other, β -linolenic acid, only absorbs by addition 4 atoms of bromine to form a fluid tetrabromide with the composition, $C_{18}H_{30}Br_4O_2$.—C. A. M.

Linolenic acid; Constitution of —. E. Erdmann, F. Bedford and F. Raspe. Ber., 1909, 42, 1334—1346.

THE linolenic acid obtained by the reduction of the hexabromide from the mixed fatty acids of linseed oil (see preceding abstract) when treated with ozone, yields a mixture of two ozonides, $C_{18}H_{30}O_{11}$ (or ozonide-peroxides, $C_{18}H_{30}O_{12}$), whilst the ethyl esters form ozonides with the composition, $C_{20}H_{34}O_{11}$ (or $C_{20}H_{34}O_{12}$). All of these compounds are colourless oily liquids. The ozonide-peroxides of the ethyl esters may be distinguished from each other by the speed at which they are decomposed by water. That readily decomposed at the ordinary temperature corresponds to α -linolenic acid, whilst that which is only slowly decomposed corresponds to β -linolenic acid. Both yield the same products of decomposition, viz., propionic aldehyde, malonic acid, and the mono-ethyl ester of azelaic acid, together with the aldehydes of malonic and zelaic acids. The two linolenic acids may be regarded as tereoisomeric, like oleic and elaidic acids, and the chemical constitution of linolenic acid may be expressed by the formula—

—C. A. M.

Horse-chestnut oil. M. Stillesen. Chem.-Zeit., 1909, 33, 497—498.

HE dried and finely-divided seeds of the horse chestnut, *esculus hippocastanum*, yielded on extraction with ether om 1.5 to 3 per cent. of a yellowish-brown, somewhat acid fatty oil, but contained little, if any, ethereal oil. he extracted oil began to solidify at —20° C., and at —37° C. was of wax-like consistency. It gave the following analytical values:—Sp. gr. at 15° C., 0.9260; refractive index, n_D^{20} = 1.4747; saponification value, 194.5; iodine value, 95.4; Reichert-Meissl value, 1.51; Hehner value, 2.9; acetyl value, 13.5; iodine value of "liquid" fatty acids, 95.8; and unsaponifiable matter, 0.53 per cent. From the examination of the fatty acids by the usual methods, the oil was found to consist chiefly of olein, with

small quantities of linolin, palmitin, and stearin, and to be on the border line of the semi-drying and non-drying oils. It did not contain sulphur, but on evaporation of the solvent after the extraction there was a characteristic odour recalling that of mustard oil. This appeared to be due to some principle to which the oil probably owes its repute as an external remedy in cases of rheumatism.

—C. A. M.

Oil of colocynth seeds. C. Grimaldi and L. Prussia. Boll. Chim. Farm., 1909, 48, 93—95. Chem. Zentr., 1909, 1, 1489.

A SPECIMEN of colocynth seeds from Algiers, when extracted with carbon tetrachloride, yielded a yellowish-red oil showing a faint green fluorescence, and having a somewhat bitter taste and a slight odour characteristic of oils from *Cucurbitaceae*. The oil was soluble in boiling absolute alcohol, and in ether, petroleum ether, chloroform, benzene, carbon bisulphide, and amyl alcohol, but only slightly soluble in boiling 95 per cent. alcohol. It had the sp. gr. 0.9289 at 15° C. and 0.8733 at 100° C., referred to water at 15° C.; solidifying point, 14° C.; Zeiss butyrorefractometer reading, 78.2 at 15°, 72.3 at 25°, and 63.5 at 40° C.; "thermal value" in Tortelli's apparatus, 86.4; acid value, 2.7; Hehner value, 90.72; saponification value, 191.7; iodine value (Hübl), 120.37; Reichert-Meissl value, 0.32. The fatty acids had the sp. gr. 0.8537 at 100°/15° C.; m. pt., 29.2°—30° C.; solidifying pt., 26.2°—27.2° C.; butyrorefractometer reading, 56.7 at 30°, 51.5 at 40°, and 48.3 at 45° C.; acid value (neutralisation value), 192.6; saponification value, 198.2; iodine value (Hübl), 121; "absolute iodine value" (Tortelli and Ruggeri), 150; liquid fatty acids, 56.2 per cent., and solid fatty acids, 43.8; mean molecular weight of insoluble acids (Hehner), 272. In the Livache test, 100 parts of the oil absorbed 5.22 per cent. of oxygen in 3 days and 5.76 per cent. in 7 days.—A. S.

Oil [Zachun oil] of Balanites aegyptiaca (Arab.: heglig).

Third Report of the Wellcome Research Laboratories, Gordon Memorial College, Khartoum, 1908, 412. (See this J., 1909, 495.)

THE heglig fruit resembles a dried date and weighs about 7.5 grms. The kernel, which amounts to 9.5 per cent. of the whole fruit, contains 43.57 per cent. of oil. The latter (see Lewkowitsch, Chem. Techn. and Anal. of Oils, Fats, and Waxes, 4th edition, Vol. 2, p. 185, under "zachun oil") has the following characters:—Sp. gr. at 100°/100° C., 0.88919; saponification value, 186.5; iodine value, 99.2; m. pt., about 8° C. It gives no reaction in the Beechi, Baudouin, and Halphen tests; in the claidin test, it forms a buttery mass which separates from a liquid portion.

—A. S.

Fats and oils; Theory of the hydrolysis of —. J. Kellner. Chem.-Zeit., 1909, 33, 453.

IN two of the author's experiments palm-kernel oil was partially saponified with an aqueous solution of alkali, until the fat separated from the mass had an acid value of 96.3 and 193.3 respectively. The amounts of glycerol in these partially saponified fats were 8.26 and 3.41 per cent., whilst the theoretical quantities for quadrimolecular hydrolysis were 8.34 and 3.31 per cent. respectively. When, however, the saponification was carried out in an autoclave, the proportion of glycerol in the partially hydrolysed fat was greater than would be possible on the assumption of a quadrimolecular hydrolysis. Thus in three typical experiments the respective amounts of glycerol found were 12.16, 5.28, and 2.11 per cent., as against 10.22, 3.17, and 1.37 per cent. theoretically required for a quadrimolecular hydrolysis. The author therefore concludes that mono- and diglycerides are present in fats partially hydrolysed in an autoclave either by means of zinc oxide or of water alone, but not in those hydrolysed with an aqueous solution of alkali under atmospheric pressure. (See also this J., 1898, 1107; 1899, 1031; 1904, 905; 1906, 856; 1907, 24, 263, 623; 1908, 693.)—C. A. M.

3-Hydroxy-5-methylfurfural as cause of some colour reactions of hexoses. Van Ekenstein and Blanksma. See XVI.

PATENTS.

Castor oil; Method of rendering — miscible with mineral oils. L. E. Common, Sutton-on-Hull, and The Hull Oil Manufacturing Co., Hull. Eng. Pat. 15,496, July 21, 1908, and 19,140, Sept. 11, 1908.

THE lubricating value of castor oil is increased by mixing it with about 1 per cent. of a reducing agent such as formaldehyde and heating to about 500° F. for some time. By this treatment it is rendered soluble in mineral oils, but before being dissolved in the hydrocarbon oil, its viscosity may be increased by blowing air through it at a temperature of about 250° F.—J. A.

Fatty acids; Process of separating liquid from solid —. E. Twitchell, Wyoming, Ohio, U.S.A. U.S. Pat. 918,612, Apr. 20, 1909.

A RELATIVELY small amount of a sulphonated fatty acid is dissolved in the liquid fatty acids, which may then be separated from the admixed solid fatty acids by washing with water, the liquid oily layer being subsequently decanted from the washing water. Or the mixed fatty acids may be formed into an emulsion, and the liquid fatty acids washed out of the finely-divided mixture.—C. A. M.

Pigments or lakes [from naphthanthraquinone]; Manufacture of —. J. V. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 18,616, Sept. 4, 1908.

WHEN naphthanthraquinone is mixed with substrata (such as alumina, china clay, and *blanc fixe*), pigments are obtained which have a good yellow shade and are fast to water, lime, light, alcohol, and oil. They also have good covering power. The naphthanthraquinone is obtained in a fine state of division by pouring its solution in concentrated sulphuric acid on ice and water, filtering, and washing with hot dilute caustic soda solution. The product obtained by grinding together a paste containing 5 parts of naphthanthraquinone and 50 parts of a 44 per cent. aluminium hydroxide paste, filtering, drying, and grinding is very suitable for lithographic and three-colour process printing inks. The pigment obtained from 100 parts of barium sulphate and a paste containing 10 parts of naphthanthraquinone is suitable for use in the form of a paint, and a further example is given in

which 10 parts of aluminium sulphate, 20 parts of barium sulphate, and a paste containing 5 parts of naphthanthraquinone are mixed and treated with 5 parts of sodium carbonate. The product is filtered and pressed.—J. C. C.

Lake from sulphonated azo dyestuffs. E. Würthner, Assignor to G. Siegle and Co., Stuttgart, Germany. U.S. Pat. 918,244, April 13, 1909.

A METALLIC compound which forms a lake base is mixed with one of the components of a sulphonated azo dyestuff, and the mixture is combined with the remaining component.—T. F. B.

(B).—RESINS, VARNISHES.

Acid value of resins; Determination of —. J. Marcusson and G. Winterfeld, Chem. Rev. Fett- u. Harz-Ind., 1909, 16, 104–107.

A MIXTURE in equal parts of absolute alcohol and benzene readily dissolves the free acids in resins, giving in a short time results in agreement with those obtained by repeated extraction of a resin with boiling alcohol. From 3 to 4 grms. of the finely-powdered sample are heated for a short time beneath a reflux condenser with 200 c.c. of the solvent, and the liquid then cooled and titrated with *N*/10 sodium hydroxide solution, without previous filtration from insoluble matter. Complete solution occurs in the case of kauri and Manila copals, and mastic, sandarac, and elemi resins. When a resin contains ammonium soaps a determination of the ammonia by distillation is necessary to obtain the amount of free acid fixed by the ammonia. In the presence of calcium resinsates the method is modified as follows. From 5 to 10 grms. of the substance are heated for a short time under a reflux condenser with about 50 c.c. of a mixture of 90 parts of benzene and 10 parts of absolute alcohol. Any undissolved matter is then filtered off and washed, and the filtrate diluted with 30 c.c. of neutral 50 per cent. alcohol, and titrated with *N*/10 alkali solution, with phenolphthalein as indicator, until the lower layer becomes pink. When soaps of aluminium, iron, manganese, or other heavy metals are present, from 10 to 20 grms. of the sample are treated with 50 c.c. of benzene, the solution filtered, and the filtrate mixed with 30 c.c. of water containing some methyl orange, and titrated with *N*/2 hydrochloric acid until the aqueous layer, after heating and thorough shaking, remains pink. This gives the amount of acid required to decompose the metallic soaps. The two layers are now separated, and the benzene solution washed once with water, mixed with neutral alcohol, and titrated with *N*/10 sodium hydroxide solution, with phenolphthalein as indicator. An amount of alkali equivalent to the hydrochloric acid used is deducted from the result to obtain the amount neutralised by the free acids of the resin.—C. A. M.

Japan lac; The chief constituent of —. Urushiol and its dimethyl ether. R. Majima, Ber., 1909, 42, 1418–1423.

THE juice of the lac tree (*Rhus vernicifera*) was treated with alcohol and filtered, the alcohol removed, and the residue (about 80 per cent.) of crude "urushinic acid" (this J., 1907, 1245) purified by repeated treatment with petroleum spirit. The filtrate from the insoluble matter (which amounted to about one-eighth) was evaporated first at the ordinary pressure and then under reduced pressure, and left a residue which could be partially distilled (to the extent of about 41 per cent.) *in vacuo* without being decomposed. The main portion of the distillate was a light brown viscous fluid, which had a sp. gr. of 0.9687 at 21.5°/4° C. and was readily soluble in most organic solvents. It was free from nitrogen and gave the same reactions as the crude undistilled substance (*loc. cit.*). It formed dimethyl and diacetyl derivatives, and gave the reactions of divalent phenols, especially the pyrocatechol reaction. Hence the author concluded that it contained two phenolic hydroxyl groups, and that the name of "urushiol" was more suitable than "urushinic acid." The crude substance had almost the same elementary composition (carbon, 79.65; hydrogen, 9.75 per cent.) as the distillate

and the non-volatile portion is therefore probably a polymerised substance of high molecular weight. (See also this J., 1906, 61; 1908, 456; 1909, 318.)—C. A. M.

PATENTS.

Turpentine and resinous matter; Apparatus and process for extracting — from wood. G. B. Frankforter, Minneapolis, Minn., U.S.A. U.S. Pats. 918,989 and 918,990, Apr. 20, 1909.

THE wood is extracted by means of a suitable solvent, which is subsequently treated, at a temperature above its b. pt., with a "reclaiming fluid," with the result that the solvent is evaporated and removed from the wood and the "reclaiming fluid." The special apparatus claimed for this process comprises a boiler connected with a number of extraction chambers by means of pipes which pass from the upper part of the boiler to the top of the chambers, and return pipes coming from the bottom of the chambers to the lower part of the boiler. The different chambers are connected with one another, and are provided with conduits for the introduction of the "reclaiming fluid," whilst there are valves in the different conduits so that each chamber may be used successively with the boiler.—C. A. M.

Polishing compositions or inks, more especially intended for polishing the heels and soles of boots and shoes; Manufacture of —. J. Y. Johnson, London. From Chem. Fabr. Elektro, Biebrich on Rhine, Germany. Eng. Pat. 9663, May 4, 1908.

EE Fr. Pat. 390,437 of 1908; this J., 1908, 1075.—T. F. B.

(C.)—INDIA-RUBBER, &c.

Rubber trees; Manuring of —. G. A. Cowie. India Rubber J., 1909, 37, 463—467.

THE application of excess of nitrogen to the soil has often the effect of stimulating the growth of the foliage to too great an extent, causing the tree to bend over in the wind. It is therefore advisable to restrict the amount of nitrogen and to supplement it with phosphates, and especially with potash, which exerts a particularly beneficial influence on the wood of the tree. Experiments made at Deli-oeda, Sumatra, with *Hevea* trees 2 years 10 months old, give the following results after 2 years' manurial treatment:—

Manure per tree.	None.	2 lb. of pea-nut cake meal, 12 oz. of double superphosphate, 8 oz. of potassium muriate (chloride).	2 lb. of pea-nut cake meal, 12 oz. of double superphosphate.
		9	14
Average circumference of stems in inches			12

The following mixtures are recommended:—
A. For land rich in nitrogen, and where there is a good leaf growth:

	Containing:		
	Potash.	Phosphoric acid.	Nitrogen.
parts of potassium chloride	14	—	—
" " superphosphate .	—	4.50	—
" " bonemeal	—	5.60	0.2
" " oil cake.....	—	—	1.3
" " ammonium sulphate	—	—	1.6
" contain	14	10.1	3.1

400 to 800 lb. per acre.

B. For land poor in nitrogen:

	Containing:		
	Potash.	Phosphoric acid.	Nitrogen.
20 parts of potassium chloride	10	—	—
30 " " superphosphate .	—	5.4	—
10 " " bonemeal	—	2.8	0.1
24 " " ammonium sulphate	—	—	4.9
16 " " oil cake.....	—	—	1.0
100 " contain	10	8.2	6.0

400 to 700 lb. per acre.

—E. W. L.

Latex of Funtumia elastica; Coagulation of —. C. Christy. India-Rubber J., 1909, 37, 400—401, 445—446.

THE coagulation processes dealt with may be divided into two more or less distinct classes, viz.: (1), the slow method, in which coagulation is brought about in the cold; (2), the rapid method in which heat is employed. In the first class are included, (1), spontaneous coagulation, which occurs when the undiluted latex is allowed to stand exposed to the air for several weeks, and which may be hastened by dilution with 15 volumes of cold water (5 to 6 days); (2), coagulation by means of formaldehyde; and (3), coagulation by means of alcoholic creosote. To the rapid methods, class (2), belong (1), the simple boiling process, in which it is better to employ diluted latex; (2), the mercuric chloride process; (3), coagulation by means of tannic acid and heat; (4), by means of alum and heat; and (5), by means of plant juices and heat. Acetic acid, although useless as a coagulant for *Funtumia* latex, is of great value as an aid to the coagulation of fresh latex. In the case of the mercuric chloride process, the addition of acetic acid to the latex, in the proportion of 1 c.c. to the pint, is essential, otherwise no coagulation can be induced until the latex is 10 days old. The following is recommended as a good working formula: Hot water (80° F.), 20 pints; mercuric chloride stock solution, 1 oz.; fresh latex, 5 pints; the stock solution being made up of mercuric chloride, 1 lb.; water, 34 pints; acetic acid, 172 oz. Tannic acid is employed in the following proportions:—Hot water (80° F.), 20 pints; tannic acid stock solution, 1 oz.; fresh latex, 5 pints. Stock solution:—Tannic acid, 1 lb.; water, 16 oz.; acetic acid, 5 oz. Coagulation by means of plant juices is not very practicable on the large scale. Coagulation by means of formaldehyde offers several advantages over other processes, and is effected by the simple addition of about 15 c.c. of a 40 per cent. solution (commercial "formol" or "formalin") to the pint of latex. Coagulation is complete in 15 to 24 hours. The time may be shortened by the use of larger proportions of formalin, but the coagulum then obtained is not so suitable for handling. Alcoholic creosote is useful rather as a laboratory coagulant than on a commercial scale. It is found that whereas the creosote may be replaced successfully by crude phenol (carbolic acid), the purer crystalline form of the latter is quite useless for the purpose. There appears to be little doubt that the best rubber from every standpoint is produced by the cold, slow processes in which the clot is formed by the gradual development of a reticulated structure, consisting of strands and threads of (presumably) protein, in which the globules of caoutchouc become enmeshed. In the hot processes the clot is formed by the coalescing of flakes of rubber and subsequent shrinkage of the mass. Rubber prepared with formalin is of great strength and toughness, but somewhat deficient in elasticity (see this J., 1907, 1264); it is light in colour, dries quickly, is not so liable to mould as other rubbers, and resists oxidation. Rubbers prepared with mercuric chloride and tannic acid are very similar to one another in properties. They dry slowly, and appear to deteriorate fairly rapidly. Rubber prepared with plant juice (*Bauhinia*) is fairly

strong, but apt to be dead and inelastic. Boiled rubber prepared in thin biscuits is of good quality. Risk of discoloration in the rubber may be avoided by prompt coagulation of the latex. It has been found, in certain instances, that the addition of caustic alkali to the latex, when boiling, results in the production of a pure white rubber. The approximate cost of chemicals for the processes referred to are as follows:—Hot tannic and acetic acid process, 10s.; hot mercuric chloride and acetic acid process, 15s.; and formol process, £3 to £3 10s. per ton of rubber.—E. W. L.

Chloral hydrate method [in rubber analysis]. F. Frank and E. Marekwald. *Gummi Zeit.*, 1909, 23, 979.

THE authors find that the chloral hydrate method (see Weber, this J., 1903, 576) is not satisfactory either for the estimation of the rubber resins, or for the separation of these from free sulphur, or for the separation of rubber resins from paraffinoid hydrocarbons, other resins, etc.—E. W. L.

Vulcanised rubber: Spontaneous changes (deterioration) of —. K. Bing. *Z. Chem. Ind. Kolloide*, 1909, 4, 232–235. (Compare Spence, this J., 1909, 374.)

IN a number of old, hardened samples of various rubber articles, including billiard-strip, bicycle tyres, various types of reclaimed rubber, etc., the author found that the presence of sulphuric acid in the free state could be invariably shown. The deteriorated samples all possessed a characteristic smell similar to that of turpentine or varnish. The greatest amount of acid was present in those samples containing relatively little mineral matter, where that mineral matter included traces of copper or lead compounds. The influence of such compounds upon the spontaneous decomposition of various samples of vulcanised rubber was therefore investigated, the three samples selected being: (1), pneumatic inner-tubes (3 per cent. of ash, containing a considerable proportion of lead); (2), red "floating" waste; and (3), a high-grade Para-rubber mixing. In all cases the finely-ground sample was heated in an autoclave for a considerable time, with dilute caustic soda, and was then treated in various ways before being exposed to the action of the atmosphere in diffused daylight. Samples of grey inner tube, which had been heated with caustic soda in a copper autoclave, showed signs of deterioration in a few days, the change being slower the more imperfectly the sample had been freed from alkali. When an iron autoclave was used, however, the samples lasted for at least one month before deterioration became apparent. When the sample treated in the iron autoclave was moistened with a solution of copper chloride, deterioration proceeded at about the same rate as in the case of the sample treated in the copper autoclave. Red floating waste treated in an iron autoclave was found to be more durable, probably owing to the absence of lead, visible change only setting in after about 9 months. When copper chloride was added to the waste, deterioration became evident in about a week. These results were confirmed in the case of the high-grade Para-sulphur mixing. Sulphuric acid was produced in all cases. Further, it was shown that an increase in the amount of acid accompanied the advance of deterioration. Similar formation of sulphuric acid occurs at the surface of ebontite articles, and is partly responsible for the fact that old rods and tubes, etc., of ebontite, are often found to have lost their good insulating properties.—E. W. L.

Rubber resin: a new commercial product. Klassert. *Pharm. Zentralbl.*, 1909, 50, 282.

UNDER the above name a pale coloured resin, obtained from raw rubber, with a conchoidal fracture, has been introduced into commerce. It is soluble, on warming, in most organic solvents, but the greater part is deposited on cooling. It is, however, almost wholly soluble in cold chloroform and in carbon tetrachloride, forming solutions which dry in thin layers, leaving a dull, resistant varnish. The resin can be easily powdered, and has, in the powdered state, the odour of raw rubber. It promises to be a useful electrical insulating material. It becomes strongly electrical with friction. Its chemical

characters differ widely from those of most resins: iodine value, 28; acid value, 0; saponification value, 10. These figures are not materially altered after the resin has been heated for some time to over 100° C.—J. O. B.

PATENT.

Gum-like substance: Process for manufacturing a — from "Java olive oil" [Sterculia oil]. K. Wedemeyer. *Fr. Pat.* 395,733, Jan. 5, 1909.

THE oil from Java olives, when heated to a temperature of about 240° C., forms a tough, gum-like mass (see this J., 1906, 893). To prepare this substance on a large scale, the oil is heated fairly rapidly to a temperature of about 200° C., and then slowly to from 240 to 250° C. When the temperature becomes higher spontaneously, the mass is cooled by passing cold water through pipes contained in the vessel in which the oil is heated, water also being sprayed on the surface of the mass in order to prevent delagellation. The heat of the reaction suffices to evaporate the water from the mass, leaving the latter in the form of a rubber-like substance.—W. P. S.

XIV.—TANNING, LEATHER, GLUE, SIZE.

Oakwood extracts: Sugar-like substances in —. J. Jedlicka. *Collegium*, 1909, 113–120, 121–126.

THE author's investigations were carried out on Mitrovitz oakwood extract containing 14–15 per cent. of non-tannins. *Non-hydrolysed non-tannins.*—After precipitation of the tannin and colouring matters with basic lead acetate and subsequent removal of the excess of lead with sodium carbonate, the solution was treated with Fehling's solution and the cuprous oxide, after washing, converted into cupric oxide and weighed; the amount of dextrose was calculated from Ruhsam's tables. It was found that the non-tannins left after precipitation of the tannin by hide powder contained generally slightly less sugar than those obtained by precipitation with lead, showing that hide partially retains monosaccharides. Forty analyses made in the course of 8 years showed an average of 3.2 per cent. of sugars in the non-hydrolysed non-tannins. *Hydrolysed non-tannins.*—Sulphuric acid was employed for hydrolysis and was afterwards precipitated by means of lead carbonate. It was found that increasing the time of boiling did not materially increase the amount of sugar. The average amount of reducing sugar (expressed as dextrose) found was 7.0 per cent. in extracts containing 60.0 per cent. of water, the results varying from 7.4 to 6.1 per cent. As a rule when there was less sugar in the non-hydrolysed solution, more was found after hydrolysis. Probably the polysaccharides are partly hydrolysed during the extraction. *Hydrolysed extract.*—After hydrolysing a 4–5 per cent. extract solution with sulphuric acid, higher figures for sugar were obtained than by hydrolysis of the extract after detanninisation—the average being 9.2 per cent. of reducing sugar. This is due to the precipitation of sugar-yielding gums by basic lead acetate.

By fermentation with yeast and measurement of the evolved carbon dioxide, it was found that the non-hydrolysed non-tannins contained 3.5–5.3 per cent. of monosaccharides. Of the hexoses, galactose was found in quantities ranging from 0.6–1.0 per cent. of the extract. In the hydrolysed extract xylose and arabinose were found. By boiling with hydrochloric acid, pentoses were found to the extent of 4–5 per cent.—S. H.

Tanning analysis: The Zeiss immersion-refractometer and —. J. Sager. *Collegium*, 1909, 146–149, 153–158.

THE author has made experiments with the Zeiss immersion refractometer method of tannin analysis described by Zwick (*Deutsche Gerber Zeit.*, 1908, 158), and give numerous tables comparing results obtained by the method with those obtained by the shake method. Greater variations are found in the scale equivalent than those shown by Zwick, and examination of 6 oak barks gave values ranging from 0.173–0.229, corresponding

to a difference of 3 per cent. of tannin. The author points out that conditions of extraction and the amount of moisture in the sample for analysis, influence the results: an oakwood ground moist gave an equivalent of 0.196—when dried and then ground and analysed, 0.176. If the time of extraction be prolonged and the heating increased, higher results are obtained. An oakbark extracted in 4 hours gave an equivalent of 0.192. When the extraction was extended over 12 hours, the same sample gave 0.2. Very small differences in the equivalents become serious quantities when calculated to percentage. The author does not consider the refractometer method of sufficient accuracy for tannin analysis, and certainly for the detection of adulteration or admixtures, it would be necessary to have less variation in the equivalents.—S. H.

Tannin; Constitution of —. M. Nierenstein. Ber., 1909, 42, 1122—1126.

ACETYLLEUCOTANNIN, obtained by the reduction of acetyltannin, when hydrolysed yields gallic aldehyde and gallic acid. When oxidised with potassium persulphate, a dark red powder, purpurotannin, is produced, which yields naphthalene on distillation with zinc dust. When acetylleucotannin is oxidised with acid permanganate, trihydroxyglutaric acid is produced. Commercial tannin is probably a mixture of digallic acid and leucotannin.—F. SHON.

Protein substances; Action of alkalis on —. A. Kossel and F. Weiss. Z. physiol. Chem., 1909, 59, 492—498.

If chupein be left in contact with sodium hydroxide or barium hydroxide solutions at the ordinary temperature, its optical rotation in aqueous solution gradually diminishes, and this change takes place more rapidly at 38° C. Thus the optical rotation of a solution of 2 grms. of chupein sulphate in 40 c.c. of N/2 sodium hydroxide fell from -2.75° to -0.51° in a 100 mm. tube, after standing for 50 hours at 38° C. Solutions of higher proteins show a similar phenomenon. Thus the optical rotation of a solution of gelatin fell from -5.84° to -0.57° in 14 days. From that point the optical rotation showed only slight alteration. The authors attribute this change in the optical rotation to a racemisation of certain parts of the protein mol., and in support of their view point to the formation of optically inactive arginin and ornithin when the products of the reactions of chupein with alkalis are further hydrolysed. In like manner an apparently optically inactive mixture of peptones, obtained by the action of sodium hydroxide solution upon gelatin, yields optically inactive arginin on hydrolysis with boiling dilute acids.—C. A. M.

XVI.—SUGAR, STARCH, GUM, &c.

Sugar; The adsorption of —. P. Rona and L. Michaelis. Biochem. Zeits., 1909, 16, 489—498.

THE typical electronegative and positive adsorption media, e.g., china clay and ferric hydroxide, which adsorb albumin, have no effect on dextrose, acetone, or acetic acid. On the other hand, charcoal is well known to have a powerful adsorbent action on these substances. It has been suggested that the loss of sugar from solutions in presence of charcoal may be due to its destruction or oxidation, as has been proved to be the case with certain other substances, such as phenylthiourea. The authors show that this is not so. The action of charcoal in removing sugar from solution is immediate and final, not progressive. Moreover, the adsorption of sugar by charcoal may be entirely inhibited by the presence of a sufficient quantity of another substance, such as acetone or acetic acid, which is adsorbed more powerfully than the sugar. The practical value of this observation lies in the fact that a dilute solution of sugar, to which 10 per cent. of acetic acid or acetone has been added, may be decolorised by shaking with 5 per cent. of charcoal without any loss of sugar. This applies both to dextrose and to sucrose, and the charcoal has no inverting action on the latter sugar. The presence of albumin, on the other hand, does not influence the adsorption of sugar or acetone by charcoal. The adsorption of sugar by charcoal is a "mechanical" and not an electrical adsorption. The curve showing the concentration of sugar in the charcoal as a function of its concentration in solution has the usual form. According to Freundlich, a substance is susceptible to mechanical adsorption if it lowers the surface tension of the solvent. This, however, does not apply to sugar, since the slight alteration in the surface tension of water, which it produces, is in the other direction. Other causes are also capable of inducing mechanical adsorption: e.g., a substance is susceptible to adsorption if it increases the compressibility of the solvent; also if its solubility is increased by increased pressure. The three causes are not necessarily interdependent nor exhibited simultaneously in the same sense, and the adsorption of sugar by charcoal is probably due to one or both of the two latter causes.

—J. F. B.

Sugars; Decomposition of the —. III. Electrolysis of dextrose. W. Löb. Biochem. Zeits., 1909, 16, 132—144.

THE author has continued his investigations of the question as to whether the synthesis and decomposition of sugar are chemically as well as biologically reversible processes, i.e., does sugar, formed by a polymerisation process from formaldehyde, undergo decomposition by a depolymerisation process involving a rupture of the aldol linkages. His previous experiments, dealing with the action of zinc carbonate (see this J., 1908, 868), zinc dust, and iron Biochem. Zeits., 1908, 12, 466) on formaldehyde and sugar proved only that formaldehyde and sugar yield the same volatile substances—acetol and methylketol. The present paper deals with the decomposition of dextrose by electrolysis. The mode of procedure was as follows:—Dextrose (10—30 grms.), was dissolved in 25 c.c. of water, 25 c.c. of 10 per cent. sulphuric acid being added to the cold solution. The liquid was placed in a porous pot (of about 100 c.c. capacity), the latter being provided with a perforated rubber stopper. A leaden worm, passing through two holes of the stopper, served as anode; a current of cold water through the worm, prevented the temperature of the solution surrounding the anode from exceeding 16° C. throughout the experiment. A bent glass tube, passing through a third hole in the stopper, served to conduct the gases evolved during electrolysis to a nitrometer. The porous

pot was placed in a glass beaker filled, to the same level as the solution in the pot, with 5 per cent. sulphuric acid, and containing a platinum cathode. The potential difference amounted to 4–5 volts. Generally, the electrolysis was continued for such a period that the amount of oxygen set in action corresponded to 1 atom per molecule of sugar. It was found that the amount of gas liberated at the anode was extremely small; in one experiment of 6 hours' duration, only 29.2 c.c. of gas (of which 20.4 c.c. consisted of carbon dioxide, and 2.4 c.c. of carbon monoxide) were liberated at the anode. In addition to unaltered dextrose, the electrolysed solutions were found to contain formaldehyde, formic acid, *d*-arabinose, *d*-arabonic or trihydroxyglutaric acid, and gluconic or saccharic acid. The experiments showed that with continued oxidation, the dibasic saccharic and trihydroxyglutaric acids were formed and finally exceeded the corresponding monobasic acids in amount. Of the possible schemes representing the formation of the products, the author selects the following:—

β-Hydroxy- γ -methylfurfural as the cause of some colour reactions of hexoses. W. A. Van Ekenstein and J. J. Blanksma. Chem. Weekblad, 1909, 6, 217–226. Chem. Zentr., 1909, 1, 1509.

The red coloration produced on treating an ethereal extract of artificial honey with resorcinol and hydrochloric acid (see Fische, this J., 1908, 1127, 1171) is due to the presence of *β*-hydroxy- γ -methylfurfural.

$\text{O.C}(\text{CH}_3).\text{CH}(\text{C}(\text{OH})_2).\text{CHO}$. One gram. of this compound was obtained from 3 grms. of artificial honey by triturating with ether, filtering, evaporating, treating the residue with water, again filtering, and shaking the solution with ethyl acetate which extracted the furfural derivative. Whilst levulose (from sucrose) on heating with oxalic acid under pressure is converted to the extent of 20 per

being made to determine the extent to which the quantity and quality of the gum are affected by the time of tapping and length of the season of exudation. The results obtained up to the present showed that gum of the earliest exudations after tapping, was usually less soluble, this being especially the case with gum from old trees; on storage such gum became quite soluble. Towards the end of the collecting season the gum became harder and more glassy, but of the samples tested in 1908, the hard gum did not yield a solution of high viscosity as is usually the case with hard Kordofan gum. There was a fairly regular decrease in "viscosity-strength" of the gum as the season advanced. The gum from the older trees was usually slightly stronger than that from younger trees. Sudan (and also Senegal) gums exhibit in their solutions two kinds of viscosity. Certain samples appear to dissolve completely to form weak solutions (5–10 per cent.), but in higher concentrations yield, especially on standing, a glairy mucus-like liquid, from which a greater or less amount of a true solution, of lower viscosity separates. This behaviour appears to be more especially characteristic of the harder tears of gums of early collections. These facts indicate the necessity of determining the solubility and viscosity of gums in solution of not less than 20 per cent. strength; moreover the results as to viscosity obtained with 20–30 per cent. solutions are more in accord with the behaviour of the gum in actual use. The abnormal gums become completely soluble even at the higher concentration when kept for some time. Short accounts of talh (*Acacia seyal*), sunt (*A. arabica*), kuk (*A. veruca*), Schwitt, kakamut or siccini (*A. sama*, Kurz), leyun (*Odina fruticosa* Hochst.), subakh (*Combretum* sp.), tartar (*Sterculia cineria*), and da or kandi (*S. tomentosa*) gums are also given.—A. S.

Sudan gums: Notes on the chemistry of the —, E. S. Edie. Third Report of the Wellcome Research Laboratories, Gordon Memorial College, Khartoum 1908, 441–450. (See preceding abstract.)

The author determined the proportions of pentoses and hexoses formed from different samples of gums on hydrolysis with 5 per cent. sulphuric acid, and the optical rotations of 10 per cent. solutions of the gums before and after hydrolysis. The chief results are summarised in the following table:—

Gum.	Pentoses.	Hexoses.	Optical rotation:	
			before hydrolysis.	after hydrolysis.
	per cent.	per cent.		
Kordofan	33.52–35.48	56.88–53.04	– 2.77° to – 3.14°	+ 5.30° to + 5.56°
Senegal	33.66–34.59	51.72–53.17	– 2.70° to – 2.93°	+ 5.42° to + 5.48°
Talh	42.61–45.50	44.31–44.74	+ 5.05° to + 5.26°	+ 7.89° to + 8.35°
Subakh	54.36	25.54	– 4.16°	+ 5.48°
Kakamut	34.74		– 1.16°	+ 6.22°
Kuk	55.70	35.63	– 0.20°	+ 7.07°
Sunt	57.80	29.21	+ 7.73°	+ 8.25°

cent. into *β*-hydroxy- γ -methylfurfural, dextrose under similar conditions yields only 1 per cent., and galactose, 1.5 per cent. The colour reactions of *β*-hydroxy- γ -methylfurfural are, in general, the same as those of furfural, but with aniline acetate solution, it gives first a yellow and then an orange colour, whereas furfural yields a red coloration. The reactions of Seliwanoff for ketohexoses, Baudouin for sesamé oil, and Molisch-Udransky for hexoses, all depend upon the presence of *β*-hydroxy- γ -methylfurfural.—A. S.

Sudan gums. Third Report of the Wellcome Research Laboratories, Gordon Memorial College, Khartoum, 1908, 414–440. (See this J., 1909, 495.)

The chief gum exported from the Sudan is that obtained in the Kordofan Province from the *Acacia verek* ("hashab"), said to be identical with the *Acacia senegal* from which Senegal gum is derived. Experiments are

Some determinations of osmotic pressure of solution of the gums (6 grms. in 100 c.c.) in Moore and Roaf apparatus (Bio-chem. J., 2, 34) were also made. Different specimens of Kordofan gum gave values ranging from 102 to 170 mm. of mercury, whilst for Talh gum the values obtained with three samples were 55, 48, and 41 mm. respectively.—A. S.

Sugar juices; Continuously working, depositing vessel for solutions and in particular for — provided with contrivances for compressing and washing the precipitates or deposits. F. Tiemann. Fr. Pat. 395,752, Oct. 28, 1908. Under Int. Conv., Sept. 24, 1908.

The apparatus includes a vessel, *a*, the upper part of which contains a chamber, *b*, of such shape that the annular space between the chamber and vessel is wider above than below. The upper rim of the chamber is fixed to the wall of the vessel by a water-tight joint. The solution passes from the pipe, *e*, through the apparatus in the direction indicated, and is drawn off through the outlet, *f*; this outlet is so placed that the floating impurities, which collect in the upper part of the annular space, are compressed and discharged through the outlet, *g*, by liquid pressure. The lower part of the vessel, *a*, contains a compression chamber, *h*, and a mixing chamber, *i*. The sedimentary impurities are compressed by a compressor, *k*, provided with blades which may be shaped like ploughshares. The compressed deposit passes to the mixing chamber, in which it is subjected to the action of a stirring device, *l*, and washed by water introduced at the inlet, *m*, the solution thus displaced passing upwards. The discharge of the washed deposit is effected by the water-pressure, and may be controlled by a suitably regulated piston or pump, *o*, connected with the exit pipe.—L. E.

Enzymes; Electrical migration of —. III. Malt diastase. L. Michaelis. Biochem. Zeits., 1909, 16, 231—234. (See also this J., 1909, 253.)

MALT diastase was subjected to dialysis in 2 per cent. solution for several days and the solution was then used in constructing the cell:

Silver in sodium chloride	Water	Diastase	Water	Copper in cupric chloride
---------------------------	-------	----------	-------	---------------------------

After 24 hours the diastase was found to have migrated largely towards the cathode, but a small quantity was always found to have migrated towards the anode. In acid solution, 0.5 per cent. of acetic acid being present in each of the three interior compartments, the migration of the diastase took place only towards the cathode, never towards the anode. With 0.2 per cent. of sodium carbonate in the three interior compartments, the enzyme migrated exclusively towards the anode. In the undialysed condition, commercial malt-diastase migrates only towards the cathode owing to the influence of electrolytes. Diastase is therefore amphoteric, as was also shown by the adsorption experiments (this J., 1908, 791). It differs from trypsin, which is also amphoteric, in the fact that it is more strongly positive, whereas trypsin is preponderantly negative.

IV. *Pepsin.*—In the arrangement:

Silver in sodium chloride	Hydrochloric acid	Pepsin and hydrochloric acid	Hydrochloric acid	Copper in cupric chloride
---------------------------	-------------------	------------------------------	-------------------	---------------------------

there is a migration of hydrogen ions with the current, and a replacement by sodium ions from the first compartment, so that the degree of acidity decreases. Since the behaviour of pepsin depends on the degree of acidity, it is necessary to keep this constant by using hydrochloric acid instead of sodium chloride in the first compartment. Then, without hydrochloric acid, pepsin is anodic; with acidities of *N*/400 and *N*/200, it is amphoteric, whilst with *N*/50 acid it is cathodic. Pepsin only exerts proteolytic action in presence of a distinct proportion of acid, i.e., when it is cathodic; in neutral media it is anodic, and then, the author suggests, it is probably the same ferment as rennet.—J. F. E.

Enzyme actions; Inhibition of — by mercuric chloride and their restoration. S. Hata. Biochem. Zeits., 1909, 16, 156—187.

THE author has investigated the influence of varying quantities of mercuric chloride on the action of pepsin, trypsin, rennet, ptyalin, the proteolytic enzyme of horse's liver, and catalase, and has also made experiments on the regeneration of the activity of the enzymes (1), by precipitation of the mercury with potassium sulphide; (2), by treatment with potassium cyanide whereby the mercury, though left in solution, is converted into non-dissociable mercuric cyanide. It was found that mercuric chloride inhibits the action of the enzymes; a considerable quantity of mercuric chloride is required to deprive pepsin, trypsin, and rennet of their activity, whereas only very small quantities are required to prevent the action of ptyalin, the proteolytic liver enzyme, and catalase. In no case did the author observe an undoubted acceleration of enzyme action as a result of addition of mercuric chloride. With regard to restoring the activity of the enzymes, experimental difficulties were encountered in the case of pepsin, whilst with the other enzymes it was found that their activity can be restored by one or other of the above-mentioned methods (the activity of ptyalin can be restored by either method). The experiments also showed that the enzymes are less readily precipitated by mercuric chloride than the proteins accompanying them. Hence, by means of mercuric chloride, it is possible to effect a partial removal of proteins from an enzyme preparation of high protein-content. The mercuric chloride left in solution is removed by a precipitant such as potassium sulphide, the activity of the enzyme being thereby restored.—L. E.

Cold-malt [Kaltmalz]. E. Jalowetz. *Woch. für Brau.*, 1909, 26, 215–216.

THE author describes a method for obtaining a chit-malt, which can be mashed without any admixture of long-grown malt; such malt he terms cold-malt (Kaltmalz). If a steeped barley is heaped to a depth of 50 cm. (20 inches) on a cold floor at a temperature of about 2° R. (36°–37° F.) and is treated in the usual way, it chits after 5–6 days and is finished after 13–15 days, its modification and yield of extract being excellent. If such malt is observed at the period of chitting, it will be found to have a good aërospire growth, while the modification of the endosperm has spread to a considerable distance. In consequence of the low temperature of the air, germination has proceeded only in the direction of the plumule, the growth of the radicle being restricted. If the germination is interrupted at this stage, the so-called 'cold-malt' is obtained. The analytical results for two such malts show (1), saccharification to take place in 20–25 minutes; (2), modification to be somewhat below the normal, the difference between the extracts with coarse and fine grinding being 4.2 and 4.5 per cent. in the two cases. The same two malts had (1), 27 and (2), 23 per cent. of half-grown, and (1), 62 and (2), 50 per cent. of three-quarter-grown corns.—T. H. P.

Spirit duties in the United Kingdom. Board of Trade J., May 13, 1909. [T.R.]

FOLLOWING is a list of duties on certain spirits, etc., payable on or after April 30th, as fixed by General Order No. 15 of 1909:—

		Rates of duty.		
		£ s. d.		
Unenumerated spirits—				
Not sweetened:				
Imported in casks or bottles	Proof gall.	0	15	2
Perfumed spirits:				
Imported in casks	Liquid gall.	1	4	1
Imported in bottles	„	1	5	1

Citric acid fermentation. R. O. Herzog and A. Poletzki. *Z. physiol. Chem.*, 1909, 59, 125–128.

THE results of investigations on the action of cultures of *Citromyces* isolated by the authors are described. The production of citric acid stands in no relation to the amount of mycelium or spores developed by the growth of the fungus, but it appears to be influenced by the form of the culture flask. There is a certain amount of relationship between the proportion of nitrogen in the medium and the yield of citric acid; the concentration of phosphoric acid in the medium also has an influence, but the total composition of the medium appears to affect the influence exerted by the single factors. The concentration of the sub-stratum from which the citric acid is being formed has a considerable effect on the yield of citric acid. Without neutralisation of the acid produced, the maximum conversion in the case of dextrose is obtained at concentrations of 5–10 per cent., amounting to a yield of about 25 per cent. of the sugar taken. The constitution of the substance fermented has a great influence on the yield. The following yields were obtained from 5 per cent. solutions, the experiments lasting over a period of 5 to 9 weeks:—Maltose, about 50 per cent.; sucrose, 30; lactose, only traces; arabinose, 5; xylose, 11; dextrose, 24; levulose, 13; galactose, 8; mannose, 12–19; mannitol, 3; erythritol, nothing; glycerol, 24–29; the yields all being calculated as percentages of the amounts of substratum taken. Ethyl alcohol gave a good growth of fungus, but no citric acid; several other alcohols

behaved similarly. Several ammonium salts of organic acids were tested, without result, but ammonium malate gave a considerable yield of an acid, the nature of which has not been determined. The mechanism of the production of citric acid, particularly from a substance like glycerol, in this manner, is still obscure. It is certain however, that the citric acid is formed from a still unknown intermediate product, as the result of a whole series of changes brought about in the original substance by the activity of the fungus.—J. E. B.

PATENTS.

Malt liquors; Treatment of —. [Priming with lactose.] W. J. Melhuish, Glasgow. Eng. Pat. 1269, Jan. 18, 1909. Addition to Eng. Pat. 13,528 of 1908 (this J., 1909, 255).

THE solution of lactose used as a priming agent in the process described in the main patent may be added at any stage of the brewing operation, and a further quantity of the solution may be introduced, if required, after the brewing is completed.—W. P. S.

Products [glycerol, etc.] in addition to alcohol; Process for the production of — by fermentation of saccharine solutions, preferably maltose. A. J. Boulton, London. From F. Sparre, Wilmington, Del., U.S.A. Eng. Pat. 7813, April 8, 1908.

A SOLUTION containing a sugar, preferably maltose, is inoculated with yeast and allowed to ferment; when fermentation has reached a maximum, a quantity of the liquid is withdrawn and a portion of it used to inoculate a fresh saccharine solution. This solution is allowed to ferment and a portion of it is added to a third saccharine solution, and so on. The main bulk of each solution is allowed to ferment completely, and the residual solutions are then tested for the amount of by-products, particularly glycerol. It is found that this successive inoculation at maximum growth leads to the production of a micro-organism which will, in saccharine solutions, produce a decreased yield of alcohol but an increased yield of by-products, such as glycerol. The reserved portion of the solution withdrawn from the saccharine solution containing the most glycerol is then employed for the production of glycerol from such saccharine solutions. After complete fermentation, the alcohol is removed by distillation, and the glycerol separated from the residue by distillation under reduced pressure.—W. P. S.

Liquid suitable for the production of alcohol; Process for producing a — from straw. W. F. Giles, New York. Assignor to F. C. Norris, Detroit, Mich. U.S. Pat. 918,997, April 20, 1909.

A LIQUID suitable for the production of alcohol is obtained by methodically extracting separate quantities of straw; the first quantity of straw is heated with water under pressure, and the solution obtained is employed for extracting a second quantity of straw, fresh water being added to the first quantity, and the boiling repeated and so on. Each quantity of straw is thus boiled twice under pressure, first with the solution obtained from a previous extraction and then with water. The united solutions obtained are acidified, allowed to remain at rest until the extracted substances have been converted into fermentable material, and then neutralised.—W. P. S.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, AND DISINFECTANTS.

(A).—FOODS.

Milk; Enzymes of —. F. Bordas and F. Touplain. *Compt. rend.*, 1909, 148, 1057–1059.

THE authors have shown that it is not necessary to assume the existence of catalases and peroxidases in milk in order to explain the occurrence of the reactions based on the decomposition of hydrogen peroxide. It is the casein, or rather the calcium caseinate, which decompose hydrogen peroxide, and if this action does not occur it

boiled milk, it is because the soluble casein of Duclaux's precipitated on the casein in suspension, forming a coating on the latter, and thus preventing the decomposition of hydrogen peroxide.—L. E.

Milk; Detection of added water in altered —. A. Kling and P. Roy. *Compt. rend.*, 1909, 148, 1050—1052.

THE total nitrogen-content of milk is not altered during storage provided that the sample has been kept in a closed vessel. On this fact, the authors base the following method for detecting added water in milk which has been kept for some time:—The whole sample is weighed (its volume being found by dividing its weight by 1.033), acidified with acetic acid, and evaporated under diminished pressure on the water-bath. The dry residue is treated according to the method of Kjeldahl, the solution of ammonium sulphate obtained, being made up to a known volume; an aliquot portion is used for the determination of ammonia. The nitrogen-content of the sample, multiplied by 6.39, gives the protein-content. The protein-content of 1 litre of the suspected sample is then compared, if possible, with that of an exactly comparable sample of milk, or otherwise, with the average protein-content—33 grms. per litre—of *dépôt* milk ("lait de dépôt"). Two samples of milk, originally containing 2.60 and 27.83 grms. of protein matter per litre, were found to contain 32.58 and 28.60 grms. respectively, after 2 years' storage.—L. E.

Margarine [and butter]; Parchment paper rendered pliable by means of glucose for packing —. O. von Boltensern. *Z. Spiritusind.*, 1909, 32, 174—175.

MARGARINE and butter keep well in parchment paper which has been rendered pliable by dipping into liquid glucose (starch syrup), in spite of the fact that the latter serves as a good medium for the growth of mould-fungi under certain conditions. No trace of the characteristic mould smell is observable after the margarine has been stored for some days in such paper.—T. H. P.

PATENTS.

Milk; Method of treating [electrically sterilising] —. J. L. Goucher. Assignor to Goucher Electric Purifying Co., New York. U.S. Pat. 918,531, April 20, 1909.

THE milk is passed through a closed vessel, the velocity of the current being partially retarded at certain points; at each of these points the milk is subjected to the action of an alternating electric current of not less than 1000 volts. The milk is then cooled rapidly.—W. P. S.

Cheese; Process for the manufacture of —. J. Ragnet. *Fr. Pat.* 395,417, Oct. 17, 1908.

CRIMMED milk is treated with rennet and heated to a temperature of about 40° C., and the curd is separated, drained, pressed, and finely sub-divided. It is next placed in closed vessels and allowed to ferment, the mass being stirred occasionally to prevent the formation of lumps. Each kilo. of the fermented mass is then mixed with 600 c.c. of water containing 20 grms. of sodium chloride; the temperature is maintained at 40° to 50° C. until all lumps have disappeared and is then raised to 80° C., in order to melt the mass. While still hot the product is transferred to moulds, cooled, taken out of the moulds, dusted with starch or flour, and coloured.—W. P. S.

Pasteurising process. A. Goetz and P. A. Jones. *Fr. Pat.* 395,489, Oct. 20, 1908.

THE liquid to be pasteurised is caused to flow through a number of channels or conduits contained in a chamber and surrounded by hot water. These channels are actually narrow spaces between partition walls fitted in the chamber, and interlaced wires are placed in each channel, the object being to thoroughly divert and mix the different currents in the liquid as the latter passes through the apparatus.—W. P. S.

Butter, margarine, tallow, fats, oils, and other substances which are oxidised when in contact with air; Preservation of — by separating some of their constituents. M. Montéran. *Fr. Pat.* 395,810, Jan. 7, 1908.

THE butter, or other fat or oil, is melted in a suitable tank and drawn off into a separator in which an atmosphere of carbon dioxide is maintained. The water is thus separated from the fat, and the latter is then conducted to a tank, whilst the water, etc., flows away through a separate pipe. The fat is next passed into a closed chamber which is surrounded by a hot water-jacket and is there subjected to a low pressure in order to remove the carbon dioxide, an exhaust pump being provided for this purpose. The fat is finally run off into suitable receptacles. The whole operation is continuous and the fat is kept entirely out of contact with the atmosphere. If desired, the fat may be conducted directly from the separator to the vacuum chamber.—W. P. S.

Cream preparation and its process of manufacture. L. M. Rousseau, Erumont, France. *Eng. Pat.* 19,455, Sept. 16, 1908. Under Int. Conv., Sept. 20, 1907.

SEE *Fr. Pat.* 392,253 of 1907; this J., 1908, 1218.—T. F. B.

(E.)—SANITATION; WATER PURIFICATION.

PATENTS.

Vapours derived from refuse destructors or like apparatus; Method of and apparatus for treating —. W. E. Storey, Ramsgate. *Eng. Pat.* 15,570, July 22, 1908.

THE vapours are passed through tubes which are heated by an auxiliary furnace, and are then mixed with air which has been heated by passing through a passage at the back of the auxiliary furnace. The treatment causes the complete combustion of noxious gases present in the vapours leaving the refuse furnace. The mixture of hot gases may be employed for heating water in boilers before finally passing to a chimney shaft.—W. P. S.

Sewage and other polluted liquids; Apparatus for the bacteriological treatment of —. E. C. McCormac, London. *Eng. Pat.* 26,013, Dec. 2, 1908.

THE sewage, introduced into the lower portion of a tank, rises through a perforated false-floor in the tank and comes into contact with filtering material above the false-floor. When the liquid reaches a certain level, it is discharged by a siphon into a tube leading to a revolving distributor which sprays the liquid over the surface of filtering material contained in a second closed tank. After passing downwards through this filter, the liquid is drained off at the bottom of the tank and conducted away to any desired outfall. An overflow pipe is provided in the first filter and also a second outlet in the second filter; these come into operation when the flow of sewage is abnormal. A vent-pipe, fitted with a fan, reaches from the space below the second filter to above the cover of the tank.—W. P. S.

Water purifying apparatus. E. C. R. Marks, London. From the Oliver-Roché Co., New York. *Eng. Pat.* 27,272, Dec. 15, 1908.

THE apparatus consists of a tank containing a second tank which acts as a floating filter. The water to be filtered is introduced through a pipe into the larger tank and rises upwards through the perforated floor of the inner tank and the filtering material contained in this tank, and is then conducted by means of a flexible pipe into a small collecting tank. A float in the latter tank actuates a valve on the main supply pipe, so that as the filter bed becomes clogged, water is admitted through a by-pass into air chambers which form part of the inner tank; this sinks a little and the pressure thus caused restores the normal flow of water through the filter into the collecting tank. When the filtering tank at last rests on the bottom of the main tank, a float in the air chambers closes a valve on the main supply pipe. Means are also provided for cleansing the filter and for emptying the air chambers of water in order to re-start working of the apparatus when this becomes necessary.—W. P. S.

Water and other liquids: Means for filtering and aerating — G. W. J. Allen, Bristol. Eng. Pat. 6760 of 1909; date of application, Mar. 30, 1908.

The water is introduced into a closed chamber, the aerating gas being admitted under pressure either by the same inlet as the water or by a separate inlet. A number of filtering "candles" are suspended from a diaphragm extending across the chamber, their open ends being above the diaphragm. The aerated water is forced through the porous "candles," passing from the exterior to the interior of the same, and escapes into the part of the chamber above the diaphragm, whence the filtered and aerated water is drawn off. The chamber is provided with a sludge outlet and a safety valve.—W. P. S.

Swamp and like liquids: Method of charging — with air or gas and apparatus therefor. C. C. E. Beddoes, Wallingford, Del., U.S.A. Eng. Pat. 8722, April 21, 1908.

SEE U.S. Pat. 895,229 of 1908; this J., 1908, 945.—T. F. B.

XIX.—PAPER, PASTEBOARD, &c.

Determining carbon in aliphatic hydroxy-compounds [cellulose in cuprammonium solution, &c.]. Berl and Innes. See XXIII.

Salt-marsh rush as a papermaking material: American — J. S. Remington, D. Bowack, and B. Dixon. World's Paper Trade Review, 1909, 51, 6—8.

THE authors have investigated, on behalf of the U.S. Government, a sample of what was erroneously described as "Salt-marsh grass" (*Spartina juncea*), but which, according to a subsequent correction, was really "Salt-marsh rush" (*Juncus Roemerianus*). This is a smooth cylindrical rush, varying in diameter from $\frac{1}{8}$ to $\frac{3}{16}$ inch and having an average length of about 3 ft. It grows in large quantities along the Atlantic coast between Norfolk and Savannah, and about 1 million tons could be collected at a cost of 3 dollars per ton. Analysis of the rush showed:—Moisture, 11.9 per cent.; ash, 3.17; loss on α -hydrolysis, 20.77; loss on β -hydrolysis, 41.88; loss on mercerisation, 19.52; gain on nitration, 21.34; cellulose, 36.16 per cent., all values except the moisture being calculated on the dry material. The authors have converted this material into paper on a semi-industrial scale. The most satisfactory conditions for the preparation of the fibre were found by experiment to consist in digestion for 10 hours with 12 per cent. of sodium hydroxide under a pressure of 4 atmospheres, 37 per cent. of washed unbleached fibre being thus obtained. Owing to the highly lignified nature of the raw material, some difficulty was experienced in bleaching the product to a good colour, but this was finally overcome by the use of 10—11 per cent. of bleaching powder, acting for a considerable time. The pulp contains a proportion of an oily substance which appears to improve the quality of the paper, but which also causes a rather unusual amount of frothing. The average length of the unbeaten fibres is 2 mm., two types of fibre, a broad and a narrow, being present. The broad fibres resemble those of coniferous wood pulp, whilst the slender fibres approach those of jute or esparto in appearance and solidity. Unfortunately, the pulp contained groups of pitted cells, which were unresolved by the treatment, and remained as specks in the paper. For this reason only, the papers prepared were unsuitable for fine writing or printing

purposes, but excellent coarse papers, suitable for wrapping, common printing or writing, were prepared from the rushes, either alone or mixed with other fibres, the mechanical properties, particularly the resistance to folding and creasing, being remarkably good.—J. F. B.

Freshwater cord-grass for paper making. J. S. Remington, D. Bowack, and B. Dixon. World's Paper Trade Review, 1909, 51, 1-5.

FOLLOWING their investigations on salt-marsh grass, the authors have now experimented with freshwater cord-grass (*Spartina cynosuroides*), which is found in great quantities in Quincy, Illinois, U.S.A., and can be collected very cheaply. The dried matter resembles straw, and is of a pale yellow colour and lustrous exterior. The stalks are about 3 ft. long. At the root end the stalk is hard, compact, cylindrical, and about $\frac{1}{4}$ th of an inch thick. Treated with the usual chemical reagents, the cord-grass is superior to the salt-marsh grass (indigenous to the United States) as regards its percentage yield of cellulose, the comparative proportions yielded being in the proportion of about 53 to 36 respectively for the two fibres. Examined under the microscope, the new fibre somewhat resembles esparto, but its dimensions are greater. It is easily beaten, and in this process resembles, in many respects, hemp. The following analyses exhibit both the composition and the resemblance to the salt-marsh rush:—

	Salt-marsh rush	Freshwater cord-grass
	per cent.	per cent.
Moisture	11.90	14.98
Ash	3.17	7.04
Loss on α -hydrolysis	20.77	19.54
" " β "	41.88	43.68
" " mercerisation	19.52	18.31
Gain on nitration	21.34	25.04
Cellulose	36.16	53.47

It is more resistant to the action of boiling dilute alkali than the salt-marsh rush, which indicates that the available pulp may be expected to prove very durable in use. With regard to boiling with caustic soda, the best results were obtained with a lye of 10 per cent. strength, under 3 atm. pressure, at 130° C., for eight hours. Although the spent lyes thus obtained only showed a small excess of alkali, the boil yielded a purer and better material than when more alkali and stronger pressure were employed. For bleaching, it is advisable, following the alkali boil, and immediately after removing the pressure to wash, and then add the bleach (bleaching powder and dilute sulphuric acid) at once. The fibre is thus quickly brought to a high degree of whiteness. If not thus followed up quickly, a somewhat yellowish shade may easily remain, only removable by a second bleach. The beating requires but low power, and is soon finished. After an hour's gentle beating in the hollander the material developed its best "felting" properties, and exhibited all the properties of an ordinary normal paper-material which had undergone long beating. The average length of fibre in this condition was found to be 1.92 mm., while its width was not more than 0.01 mm.

The cord-grass fibre alone, furnishes a very good printing and writing-machine paper. By mixing with rag and cellulose, cream-aid note and letter paper, drawing paper, etc., of excellent quality were obtained. The authors predict a great future for this new paper material.

PATENTS.

Papers for filtering and like uses: Manufacture of — L. Pierucci, Pisa, Italy. Eng. Pat. 17,810, Aug. 25, 1908.

FINELY powdered gas-retort carbon is added to the usual pulp and stirred thoroughly therewith before putting the mixture on the web. The paper is said to be suitable for filtering acids, and as an abrasive substance in grinding and polishing surfaces.—G. W. McD.

Pulp used in the manufacture of paper; Method and apparatus for bleaching the —. G. Gunn, Heywood, Lancs. Eng. Pat. 23,947, Nov. 9, 1908.

THE apparatus consists of a vertical cylindrical vessel provided with a false conical bottom. The pulp is filled into this vessel from the top and any excess of water is extracted by means of a drum pump connected with the space between the bottom and false bottom of the vessel. The theoretical quantity of bleaching material is added and the contents of the vessel are circulated through a heater situated adjacent to the main vessel and then returned to the latter, a pump being provided for the purpose. At the same time the drum pump withdraws a portion of the liquid and returns it to the top of the vessel. When the bleaching action is at an end, the bleaching solution is drawn off and the pulp is washed with water; a mixing device is fitted in the vessel and a trough placed round the upper edge carries off excess of water when the pulp is washed with water introduced at the bottom of the vessel. The operations may be repeated as desired until the pulp is thoroughly bleached. Several of the vessels may be used in connection with one another, and each may be closed with a cover where it is desired to remove the bleaching solution by means of compressed air. Rags and long-fibred pulp may be bleached in the apparatus; after the first charge of bleaching agent has been added, the material is transferred to a vessel provided with a helical stirrer where it is subjected first to acid and then to alkaline treatment, washed, and again bleached.—W. P. S.

Brine; Apparatus and process for handling the electrolytic products of — in the treatment of fibre [paper pulp]. W. V. Wentworth and A. B. Larchar, Penobscot, Me., Assignors to Penobscot Chemical Fibre Co., Maine. U.S. Pats. 912,339 and 912,340, Feb. 16, 1909.

BRINE is electrolysed in a suitable cell, the chlorine being led off and converted into bleaching liquor by absorption in milk of lime. The caustic soda liquor is passed through an evaporator, where the liquid is concentrated by means of steam passed through pipes in the middle portion of the apparatus. Below the zone of concentration is a pocket, in which the crystals of salt and concentrated caustic liquor collect. The pocket discharges its contents into a vacuum chamber, and from this the mixture is driven by means of compressed air on to a sand filter. The caustic soda and bleaching liquors are employed in the preparation of paper pulp from wood fibre.—B. N.

Sheets from cores of "palm trees"; Process of making prepared —. V. and L. von Alpenburg, West Hoboken, N.J. U.S. Pat. 917,516, April 6, 1909.

SHEETS, prepared from the core of the *Aradia papyrifera*, are subjected to the action of a solution containing tannin and preservative salts, and then to the action of a solution containing glycerin and methyl alcohol, the excess of the solution being removed in each case by the application of pressure. The sheets are afterwards sized and dried.—W. P. S.

Stereotype paper; Preparation and treatment of —. D. Gestetner, Fr. Pat. 395,788, Oct. 29, 1908. Under Int. Conv., Sept. 4, 1908.

THE paper is coated with a wax composition which dries and hardens on exposure to the atmosphere. This composition is prepared by mixing Javanese paraffin wax, 1 part; carnauba wax, 1 part; and linseed or other drying oil, or fatty acids of the same, 3 parts, all by weight. The composition is kept in a molten state in a closed vessel from which the air is exhausted; a little terebene may be added, the vapours of which will fill the interior of the vessel above the molten wax, or an inert gas may be introduced into the vessel instead of exhausting the air from the latter.—W. P. S.

Stencil paper; Preparation and treatment of —. D. Gestetner, Tottenham. Eng. Pat. 18,600, Sept. 4, 1908.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

Cinchona alkaloids. X. The fission of ketones derived from cinchona bases. P. Rabe. Annalen, 1909, 365, 353—365.

FROM experiments on the interaction between amyl nitrite and quinone (this J., 1909, 381), the author considers that the constitution of quinine is represented by the following formula:—

Quinone was treated with amyl nitrite in sodium ethoxide solution at a low temperature. After standing, crystals of sodium quininate separated. These were removed, and the liquid was found to contain α -oximino- β -vinylechinclidine, m. pt. 146°—147° C. (see this J., 1908, 178). Hydrocinchoninone (this J., 1909, 381) when treated with amyl nitrite in the same way yielded on the one hand α -oximino- β -ethylchinclidine, $\text{C}_{15}\text{H}_{16}\text{N}_2\text{O}$, m. pt. 133°—134° C., and on the other hand, cinchoninic acid, m. pt. 253° C. When ethylchinclidine was digested with hydrochloric acid, the hydrochloride of cincholoiponic acid ethyl ester, m. pt. 158° C., was produced.—F. SHDX.

Cinchona alkaloids. XI. Identity of methyleinchonine and methyleinchonidine. P. Rabe. Annalen, 1909, 365, 366—376.

THE author shows that methyleinchonine and methyleinchonidine are really one and the same substance, viz., methyleinchotoxine. Since the cinchona bases are 1,2-hydramines (α -hydramines), they readily pass into iminoketones. Cinchonine methiodide was heated with acetic acid and sodium acetate. The "methyleinchonine" thus produced melted at 74°—75° C., and had $[\alpha]_D^{25} = +35.28^\circ$ at 20° C. in chloroform. Cinchonidine methiodide treated in the same way yielded a methyl derivative melting at 74°—75° C., and with $[\alpha]_D^{25} = 37.97^\circ$ at 20° C. in chloroform. Both methyl derivatives yielded the same methiodide, m. pt. 197° C. "Methyleinchonine" and "methyleinchonidine" both yield methyleinchotoxinephenylhydrazones, m. pt. 150° C. Other derivatives were prepared and found to be identical.—F. SHDX.

1,2-Hydramines. I. 2-Piperido-1-phenylethanol-(1). P. Rabe and W. Schneider. Annalen, 1909, 365, 377—382.

BY reduction with sodium and alcohol, piperidoacetophenone passes into 2-piperido-1-phenylethanol-(1), $\text{C}_{13}\text{H}_{19}\text{ON}$. This substance melts at 67°—68° C., and boils at 188° C. at 20 mm. It is colourless, easily soluble in alcohol and ether, and soluble with difficulty in water and light petroleum. The normal sulphate undergoes no change when heated to 130°—140° C. The base suffers no change when heated with dilute acetic acid. The methiodide, m. pt. 136°—137° C., is not changed when heated with sodium acetate and acetic acid. When the methiodide is heated with potassium hydroxide solution, acetophenone and N-methylpiperidine are produced, thus supporting the view of the "hydramine fission" of the cinchona bases (see preceding abstract).—F. SHDX.

Narceine. M. Freund and P. Oppenheim. Ber., 1909, 42, 1084—1101.

THE authors' experiments confirm the formula for narceine put forward by Freund and Frankforter (Annalen, 277, 20), and demonstrate the presence of the grouping,

CO_2CH_3 , in the molecule. The methiodide of narcindonine, $\text{C}_{24}\text{H}_{28}\text{NO}_2\text{I}$, forms white crystalline leaflets, m. pt. 217°C . (this J., 1907, 165). Narcindone, $\text{C}_{24}\text{H}_{28}\text{O}_7$, was prepared by the action of sodium ethoxide on the above-mentioned methiodide. It crystallises from glacial acetic acid in large, nearly colourless, hexagonal tablets, melting at $136^\circ\text{--}137^\circ\text{C}$. Narcindone forms a red sodium salt. A further analogy between phenylhydandione and narcindonine is seen in the behaviour of the latter towards bromine. Bromonarcindonine hydrobromide, $\text{C}_{24}\text{H}_{26}\text{NO}_7\text{Br}_2$, was made by the action of an acetic acid solution of bromine on sodium narcindonine dissolved in the same solvent. The substance thus formed crystallises with $1\frac{1}{2}$ molecules of acetic acid in small, nearly white tablets, decomposing at 150°C . When bromonarcindonine is treated with dilute sodium hydroxide solution, it is decomposed into hemipinic acid, and the methyl bromide of hydrocotarnine, $\text{C}_{13}\text{H}_{17}\text{NO}_3\text{Br}$, which crystallises in white needles decomposing at 221°C . A similar result is produced by the action of ammonia, only hemipinimide, m. pt. 226°C , is produced in place of the acid. When the methyl bromide, m. pt. 221°C , is treated with potassium iodide, hydrocotarnine methiodide, m. pt. 206°C , is produced. The methyl bromide, m. pt. 221°C , was boiled with a strong solution of sodium hydroxide, when a colourless basic oil was produced. This, when methylated, yielded N-methyl-*des*-hydrocotarnine methiodide, m. pt. 193°C . Narcine was dissolved in sodium ethoxide solution and amyl nitrite added at 0°C . In this way isonitrosonearcine, $\text{C}_{24}\text{H}_{26}\text{N}_2\text{O}_6$, was formed, which crystallises in white prisms, melting at 196°C , and dissolves in alkalis with a yellow colour. It forms an alcoholate, m. pt. 178°C , and a hydrate, m. pt. 173°C . The hydrochloride melts at 223°C . When isonitrosonearcine is treated with methyl iodide, it forms the methiodide of isonitrosonearcine dimethyl ester, $\text{C}_{26}\text{H}_{31}\text{N}_2\text{O}_9\text{I}$, m. pt. 247°C . When heated with a strong alkali, this methiodide decomposes into hemipinic acid, trimethylamine, and 1-vinyl-2-cyano-3-methoxy-4,5-methylenedioxybenzene, m. pt. 156°C . Isonitrosonearcine hydrate or alcoholate gives the same products when heated to 150°C . When heated to 115°C these substances yield hemipinic acid, and 1-dimethylaminoethyl-2-cyano-3-methoxy-4,5-methylenedioxybenzene, which forms a hydrochloride, m. pt. 204°C .—F. SHDN.

Alkaloids; Affinity values of certain — V. H. Veley. Chem. Soc. Proc., 1909, 25, 115—116.

DETERMINATIONS have been made of the affinity value of some of the more important alkaloids by the methyl-orange and borax precipitation methods, the latter only being put forward as giving approximate results in cases in which the electric conductivity and ester catalysis methods cannot be applied. It was shown that the affinity values of only a few alkaloids are less than $1\cdot 10^{-7}$, those of the greater number are between the limits of $1\cdot 10^{-7}$ and $3\cdot 10^{-5}$ (value of ammonia), and lastly, only a few have a value higher than the last figure, and hence may be classed with the tetra-alkylammonium hydroxides. It appears that when alkaloids consist of two conjoint residues which, if considered each by itself, would give affinity values of a widely different order, such as piperidine or benzylamine, on the one hand, and quinoline or pyrrolidine, on the other, the stronger residue is modified by the presence of the weaker. It seems to be immaterial whether each residue contains a nitrogen atom, and whether such an atom is common to both. The affinity values determined by the methods applied, and collected together for the sake of comparison, illustrate the difficulty of obtaining salts, B_2HCl , in the case of certain dinitrogen alkaloids.

Urotropine and hordenine; Reaction of — A. Labat. J. Pharm. Chim., 1909, 29, 433—435.

DENIGÈS has previously shown that formaldehyde solution, in presence of strong sulphuric acid, forms condensation-products having distinctive colours, when boiled with certain substances possessing phenolic characters. Urotropine, under similar conditions, reacts like formaldehyde. If 1 c.c. of 1 per cent. solution of urotropine be boiled with an equal volume of hordenine

sulphate solution of the same strength and 2 c.c. of strong sulphuric acid, a fine emerald-green colour is rapidly developed. A distinct reaction is evident with 0·0001 grm. of hordenine sulphate. Inversely, employing hordenine sulphate solution as the reagent, an evident reaction results with a 1:1000 solution of urotropine.—J. O. B.

Essential oils; Constituents of — Oenanthaldehyde acetate and *enol-n-octanal acetate*. F. W. Semmler. Ber., 1909, 42, 1161—1163.

Two aldehydes of the fatty series were boiled with acetic anhydride and sodium acetate. Oenanthaldehyde, or *n*-heptanal (b. pt. $42\text{--}43^\circ\text{C}$ at 10 mm., sp. gr. 0·8250 at 20°C , and n_D^{20} 1·41655) gave *enol-n*-heptanal acetate, $\text{CH}_3(\text{CH}_2)_4\text{CH}(\text{CH}_3)\text{O}\cdot\text{CO}\cdot\text{CH}_3$, which boils at $76^\circ\text{--}79^\circ\text{C}$ at 10 mm., has the sp. gr. 0·888 at 20°C , and n_D^{20} 1·43258. Octanal boils at $60\text{--}61^\circ\text{C}$ at 9 mm., has the sp. gr. 0·8211 at 20°C , and n_D^{20} 1·41955. The *enol*-acetate boils at $90\text{--}91^\circ\text{C}$ at 10 mm., has the sp. gr. 0·88 at 20°C , and n_D^{20} 1·43256. The semicarbazone of oenanthaldehyde melts at $106^\circ\text{--}107^\circ\text{C}$. *n*-Octanal oxime melts at 60°C , and boils at $111\text{--}112^\circ\text{C}$ at 9 mm.; the semicarbazone melts at 101°C .—F. SHDN.

Terpenes and essential oils, 98th Communication. Conversion of pulegone into isopulegone. O. Wallach. Annalen, 1909, 365, 240—254.

PERLEGONE in the presence of an alkali is readily converted into isopulegone by the action of hydroxylamine. —F. SHDN.

Terpenes and essential oils, 99th Communication. The preparation of unsaturated cyclic acids and hydrocarbons with semicyclic linkages. O. Wallach. Annalen, 1909, 365, 255—277.

Essential oils. H. Haensel. Chem. Zentr., 1909, 1, 1476—1477.

Oil of marsh mallow leaves.—The dried leaves of *Althaea officinalis* yielded 0·022 per cent. of a brown oil of pleasant odour, which had the sp. gr. 0·9209 at 20°C ; acid value, 88·7; ester value, 33·9. After saponification the oil yielded palmitic acid and a volatile acid with an odour resembling that of valeric acid. A specimen of *cubeb* oil, freed from terpenes, had the sp. gr. 0·9428 at 15°C , and n_D^{20} = 1·005. *Spanish broom oil* obtained in a yield of 0·031 per cent. from *Spartium scoparium*, L., was dark brown in colour, and liquid at the ordinary temperature, but partially solidified on cooling to 0°C . It had the sp. gr. 0·8673 at 15°C ; acid value, 58·6; ester value, 29·4. It contained furfural, palmitic acid, and 3·5 per cent. of a paraffin hydrocarbon which crystallised from alcohol in needles melting at $48\text{--}49^\circ\text{C}$. *Oil of hazel leaves (Corylus avellana)* was obtained in a yield of 0·0425 per cent. It was light brown in colour, solidified at about 30°C , and contained 18 per cent. of palmitic acid, and a paraffin hydrocarbon melting at $49\text{--}50^\circ\text{C}$. It had the acid value, 60·4; ester value, 24·6; ester value after acetylation, 158; in the superfused condition its sp. gr. was 0·8844 at 25°C . The unsaponifiable portion of the oil distilled over between 170 and 295°C . *Monk's pepper oil* was obtained in a yield of 0·36 per cent. from the leaves of *Vitex agnus castus*, as a mobile, reddish-brown oil with an odour of camphor. It had the sp. gr. 0·8993 at 20°C ; acid value, 5; ester value, 20·8; ester value after acetylation, 56·5. It contained palmitic acid, pinene, cineol, a sesquiterpene (b. pt. at 20 mm., $136^\circ\text{--}138^\circ\text{C}$; sp. gr. 0·9209 at 16°C ; n_D^{20} = 1·498), and probably also an unstable sesquiterpene-alcohol.—A. S.

Resorcinoform; Method of preparing — D. Monteil. L'Union pharm., 1909, 50, 159.

110 GRMS. of resorcinol are dissolved in about 100 grms. of commercial formaldehyde solution; sufficient hydrochloric acid is added to the cold solution to cause precipitation. Considerable heat is generated, and the mixture becomes a pink paste, which must be kept well stirred. It is then drained on a filter and dried at 25°C . The amorphous currant-red powder thus obtained is termed resorcinoform; it is an active antiseptic for medicinal use.—J. O. B.

Carbon dioxide; Fixation of — by alcohols, sugars, and hydroxy-acids. M. Siegfried and S. Howwjanz. Z. physiol. Chem., 1909, 59, 376—404.

In the course of the authors' experiments on the fixation of carbon dioxide by amino-compounds (this J., 1905, 451), it was found that in the presence of alcohol a larger proportion of the gas was absorbed. Further experiments have shown that this is due to the alcohol combining with the carbon dioxide, and that other alcohols and also sugars and hydroxy-acids give this *hydroxyl carboxylic reaction*. When carbon dioxide is conducted into milk of lime at 0° C. in the presence of hydroxyl bodies of the fatty series, the filtrate, on standing or heating, deposits calcium carbonate in amounts constant within certain limits for each hydroxyl group. The reaction, which will take place in very dilute (0.1 per cent.) solutions, cannot be due to the formation of colloidal calcium carbonate, since the alkaline filtrate becomes acid on the separation of the calcium carbonate on standing. This agrees with the theory of the formation of salts of hydroxy-carboxylic acids, which are subsequently decomposed with the liberation of carbon dioxide; and other experiments support this conclusion. Under parallel conditions methyl alcohol combines with about three times as much carbon dioxide as ethyl, propyl, or normal or iso-butyl alcohols, whilst tertiary butyl alcohol is practically inert. Polyvalent alcohols can fix one or more mols. of carbon dioxide, the highest value being obtained with mannitol. The difference in absorptive capacity between monovalent and divalent alcohols is very pronounced, but the power of absorption only shows a slight increase in proceeding up to hexavalent alcohols. With regard to sugars, pentoses fix less than $\frac{1}{2}$ mol. of carbon dioxide, whilst dextrose and levulose combine with exactly $\frac{1}{2}$ mol., and galactose with somewhat more. Bioses form compounds containing approximately 1.1 mol. of carbon dioxide. Fermentation lactic acid and paralactic acid fix carbon dioxide in the proportion of about 1 mol. to 4 of the acid; but hydroxyisobutyric acid (like tertiary butyl alcohol) shows practically no reaction.—C. A. M.

Chemical action of light. Ciamician and Silber. See XXIV.

PATENTS.

Physiologico-chemical substances; Process for raising the temperature of substances containing bodies sensitive to change, especially applicable to —. F. J. Brougham, London. From W. von Preyss, Baden, Austria. Eng. Pat. 7613, April 6, 1908.

THE patent relates to a process for the production of therapeutic serums, enzymes, etc., enabling them to be produced partly more rapidly and partly with a modified action compared with other methods. The process consists in causing suitable high-frequency electric currents to act on organs containing sensitive substances, said currents being of such voltage and intensity as to cause heat to be generated to a sufficient extent and the desired final products to be thereby formed or a certain influence exerted on their formation.—G. W. McD.

Theophyllin compound. R. Grüter, Assignor to Chem. Werke vorm. Dr. H. Byk, Charlottenburg, Germany. U.S. Pat. 919,161, Apr. 20, 1909.

CLAIM is made for the manufacture of double compounds of theophylline and aliphatic diamines, produced by the interaction of the respective substances in molecular proportions. Thus the theophylline may be dissolved in the liquid diamine and the solution dried over a hygroscopic substance, or the theophylline may be dissolved in an aqueous solution of the diamine and the liquid evaporated *in vacuo* over a drying substance. The new compounds, which have diuretic properties,

form white crystals which are readily soluble in water, but less soluble in alcohol and ether. They are decomposed by acids with the liberation of theophylline, whilst heat decomposes them into their components.—C. A. M.

Scandium or scandium compounds; Preparation of — from minerals. R. J. Meyer. Ger. Pat. 208,355, June 2, 1908. Addition to Ger. Pat. 202,523, March 15, 1908.

THE hydrofluoric acid used, according to Ger. Pat. 202,503 (this J., 1909, 108), for separating scandium from other metals, especially iron and manganese, is, according to the present patent, replaced by hydrofluosilicic acid or a soluble silicofluoride.—A. S.

Salts of the mercury derivatives of fatty acids of the formula,
 $\text{Hg}(\text{OH})\text{CHR}.\text{CO}_2\text{Me}$, and the corresponding anhydrides.

(R=hydrogen or alkyl); Process for preparing —. W. Schoeller and W. Schrauth. Ger. Pat. 208,634, July 11, 1907.

MERCURIC oxide is treated with one to two mols. of a malonic ester or a monoalkylmalonic ester in presence of water, and the resulting monomercurimalonic ester is saponified by means of an alkali; the resulting alkali salts of mercurimalonic acid are readily converted into anhydrides of the above formula by treatment with dilute acids, carbon dioxide being eliminated, and these are converted by alkalis into the alkali salts of the corresponding acids; e.g., when a malonic ester is used, the alkali salts of hydroxymercuriaacetic acid are obtained.—T. F. B.

Isobornyl esters from pinene hydrochloride; Process for preparing — by heating with an organic acid in presence of a silver salt. G. Wendt. Ger. Pat. 208,636, Nov. 16, 1907.

PINENE hydrochloride is almost quantitatively converted into an isobornyl ester by heating with an organic acid in presence of silver fluoride, with or without addition of silver sulphite. It is advisable to remove the hydrofluoric acid liberated by passing a current of carbon dioxide through the mixture. The silver is recovered quantitatively as chloride. The silver fluoride obtained from 1 part of silver nitrate is added to a solution of 1 part of pinene hydrochloride in 2 or 3 parts of glacial acetic acid; 0.1 part of silver sulphite is added, and the solution is heated to 50°—60° C. for 8 to 16 hours, a current of carbon dioxide being passed during the process.—T. F. B.

Santalol esters of bibasic acids; Process for preparing neutral, mixed —. J. D. Riedel A.-G. Ger. Pat. 208,637, Jan. 28, 1908.

MIXED santalol esters of bibasic acids are produced by treating monosantalyl esters of these acids with dialkyl sulphates or alkyl esters of sulphonic acids in alkaline solution. Santalylsuccinic acid methyl ester, santalyl-phthalic acid methyl ester, and santalyleamphoric acid methyl ester are described in the specification.—T. F. B.

Cotarnine cholate; Process for preparing —. F. Hoffmann-La Roche und Co. Ger. Pat. 208,923, July 16, 1908. Addition to Ger. Pat. 206,696, Sept. 29, 1907 (this J., 1909, 383).

COTARNINE cholate is prepared by the action of a salt of cotarnine on a salt of cholic acid in presence of alcohol.—T. F. B.

Oxyarylsarinic acids; Process for the manufacture of reduction products of the —. O. Imray, London. From Farbwerke vorm. Meister, Lucius, und Brüning. Hoechst on Maine, Germany. Eng. Pat. 9855, May 6, 1908.

XXII.—EXPLOSIVES, MATCHES, &c.

Matches in China. Chem. Ind., 1909, 32, 205.

THE manufacture of matches in China is increasing, and hence the imports show a falling-off, although the demand continues to increase. The imports of materials for match manufacture (powdered glass, phosphorus, paraffin wax, potassium chlorate, and match-wood), on the other hand, have increased. These materials are obtained chiefly from Japan, although some of them are not manufactured there and have to be imported, for instance phosphorus from Great Britain and potassium chlorate

from Germany. Most of the finished matches imported by China also come from Japan. Whilst German and Swedish matches cannot be supplied at less than £6 5s. to £6 13s. 4d. per case, the best Japanese matches are sold at £5 4s. 2d. per case, and the Chinese matches are still cheaper. In the Canton district three match factories were in operation in 1907, and in consequence of the decree of 1907 excluding Japanese goods, it has been proposed to establish a company with a capital of £20,000 for the manufacture of matches in China. Wood suitable for matches has been discovered near Hankow and in the neighbouring province of Kuangsi.—A. S.

Determining perchlorate. Rothmund. See XXIII.

PATENTS.

Blasting cartridges; *Means for waterproofing —.* A. Larsen, London. Eng. Pat. 13,890, June 30, 1908.

IN order to waterproof cartridges for use in wet boreholes, a bonnet of india-rubber or other suitable material is used, which is adapted to fit tightly over the end of the cartridge. The open end of the bonnet is contracted so that it may firmly grip the outer cartridge surface. The rear end of the bonnet is provided with a short length of tubing which serves as a means for holding the electric wires or fuse of the detonator. Owing to the elasticity of the rubber, the extra grip exerted by the front end of the bonnet will increase, if the electric wires or the fuse should be unduly pulled during stemming.—G. W. McD.

Explosives and process of making the same. A. J. Boulton, London. From A. La Motte, Wilmington, Del., U.S.A. Eng. Pat. 7921, April 9, 1908.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS.

Viscosity of petroleum illuminating oils and an apparatus for its determination. Ubbelohde. See III.

PATENTS.

Calorimeter-lamp. H. Junkers, Aix-la-Chapelle, Germany. U.S. Pat. 918,659, April 13, 1909.

IN a liquid fuel calorimeter-lamp the liquid to be burned is contained in a reservoir suspended from one arm of a balance, so that the quantity of fuel burned can be determined from the loss in weight. The reservoir is provided with a bent tube carrying a burner which freely enters the calorimeter proper, a filling tube, a pressure gauge and means for increasing the pressure within the reservoir so that the liquid fuel is forced into the burner.—W. H. C.

Measuring different kinds of liquids; *Apparatus for —.* N. Gerbers Co., Ges.m.b.H. Ger. Pat. 207,958, Feb. 21, 1908.

Two forms of the apparatus are described. In that shown in Fig. 1, the liquids to be measured are contained in A and B; on pressing the ball, E, the liquid in A is forced into the measuring pipette, g, and that in B into the pipette, h. The latter when in its lowest position closes the outlet of g, and at the same time its own side outlet opening, i. By raising the pipette, h, both the liquids

FIG. 1.

FIG. 2.

re delivered together. In the modified apparatus shown in Fig. 2, the openings of the two pipettes are controlled simultaneously by means of *z*.—A. S.

INORGANIC—QUALITATIVE.

Fischer's salt; *Precipitation of — usually considered to be potassium cobaltinitrite.* L. L. De Koninck. Bull. Soc. Chim. Belg., 1909, 23, 200—202.

For the detection of potassium the author uses the following solution:—50 grms. of cobalt nitrate are dissolved in 1 litre of water acidified with 25 c.c. of nitric acid (sp. gr. 1.2) and poured into a solution of 300 grms. of sodium nitrite in 1 litre of water. After 24—48 hours the solution is decanted or filtered from a small quantity of the potassium salt which is deposited. The solution is a bright orange colour and when added to a neutral solution of a potassium salt, a yellow precipitate is immediately produced unless the solution is extremely dilute. The limit of the reaction is about 1:10,000. In order to precipitate cobalt, the use of a solution containing 5 grms. of sodium nitrite and 22 grms. of potassium nitrate in 100 c.c. of water is recommended.—J. C. C.

INORGANIC—QUANTITATIVE.

Antimony; *Separation of —, from solutions of thioantimonates.* W. Schulte. Metallurgie, 1909, 6, 214—220.

From a strongly alkaline solution of sodium thioantimonate, aluminium in the form of shot or powder (but not in heat) precipitates metallic antimony. With shot, the weight of antimony precipitated is never more than one-third of that of the aluminium used; with powder, the action is more rapid, and nearly (but not quite) the whole of the antimony can be precipitated. A more prolonged action of the aluminium results, however, in some of the antimony being redissolved. Magnesium powder acts much more strongly than aluminium, producing considerable rise of temperature and rapid evolution of hydrogen sulphide; and the precipitation of the antimony is so complete that it can be used as an analytical method of determining antimony in a solution of thioantimonate containing no other metals of the group. In all these reductions, traces of the antimony are converted into stibine—no evidence of the formation of stibine in alkaline solutions had previously been given. In the electrolytic determination of antimony the author finds, with Fischer, a gradual loss of weight of the platinum cathode—about 0.5 mgrm. for each determination. He contests Fischer's statements, however, that this loss does not occur if the electrolysis be carried out at the ordinary temperature, and that the anode also suffers loss. By using appropriate electrolytes and current densities, it is possible either to refine Britannia metal electrolytically, or to separate its antimony and deposit it as pure antimony on the cathode. —J. T. D.

Antimony and tin; *Separation of —.* G. Panajotow. Ber., 1909, 42, 1296—1299.

A METHOD is based upon the difference in solubility of the sulphides of antimony and tin in dilute hydrochloric acid

Thus antimony is quantitatively precipitated by hydrogen sulphide at the ordinary temperature from its solution in 15 per cent. hydrochloric acid, whilst tin is not precipitated under those conditions. In the case of mixtures, the precipitate of antimony sulphide obtained at the ordinary temperature invariably contains traces of tin, but if the precipitation be made at 50°—60° C. the precipitate will be free from tin. The solution of the mixed salts in 15 per cent. hydrochloric acid is heated to 50°—60° C. in the water-bath, and a current of hydrogen sulphide passed through it for 30 minutes, after which it is cooled to 30° C. and the current of gas continued for 10 minutes. The precipitate is then rapidly filtered off in a Gooch's crucible previously dried at 110° C., and washed with 15 per cent. hydrochloric acid saturated with hydrogen sulphide. It is next washed successively with water saturated with hydrogen sulphide, with alcohol, with a mixture of alcohol and carbon bisulphide, with carbon bisulphide alone, with alcohol, and with ether, and is finally dried at 110° C., and weighed. The filtrate containing the tin is partially neutralised with ammonia, diluted with water, and heated, and the tin precipitated with hydrogen sulphide. The results are independent of the proportion of the two metals in solution, and, as is shown by test analyses, are very accurate.—C. A. M.

Tungsten; *Determination of —.* M. Tschilkin. Ber., 1909, 41, 1302—1304.

KNOBBE proposed originally the use of benzidine for the determination of tungsten (this J., 1908, 812). The author has found equally good results are obtained with *a*-naphthylamine in place of benzidine. Thus in the analysis of commercial sodium tungstate, the tungstic acid may be precipitated by either *a*-naphthylamine or benzidine. To 100 c.c. of a reagent, containing in a litre 25 grms. of the base, and one and a half times the theoretical quantity of hydrochloric acid, 25 c.c. of a 2 per cent. solution of sodium tungstate are added. After standing for 3 hours in the cold, the precipitate is filtered off and washed with the diluted reagent (1:5). It is then ignited in a platinum crucible, and weighed as tungsten trioxide.—J. N. G.

Electro-analysis; *Rapid —.* H. Filippo. Chem. Weekblad, 1909, 6, 226—229. Chem. Zentr., 1909, 1, 1502.

From 30 to 60 grms. of mercury are introduced into a flask, in the round bottom of which is sealed a platinum wire, 0.5 mm. thick and 2 cm. long, the end of the wire being flush with the inner surface of the flask. A platinum wire formed into a spiral at the end is used as anode. After making connection with the source of current, the solution to be electrolysed is introduced into the flask, and an inert electrolyte (sulphuric acid, nitric acid, sodium sulphate) added in such quantity that with a voltage of 6—10 volts, the current strength is 2—4 amperes, the anode being about 1 cm. above the mercury cathode. In most cases the mercury is set in motion automatically. When the electrolysis is complete, the solution is removed with a pipette, without stopping the current, the cathode washed twice with water and once with alcohol, and then after removing most of the alcohol with a pipette, the amalgam with the remainder of the alcohol is transferred to a weighing bottle, and washed once or twice with alcohol; then the alcohol is removed with a pipette and by means of filter-paper, and the amalgam dried at 50° C., and weighed.—A. S.

Mercury cathode; *Use of a — in the determination of metals.* A. H. Porter and F. C. Frary. Trans. Amer. Electrochem. Soc., 1908, 14, 51—58.

PRICE (this J., 1907, 345) found that low results are obtained when zinc is deposited upon a mercury cathode. He also stated that when pure mercury is washed with alcohol and ether, it loses weight and a black scum is formed. The authors show that this black scum must have been due to impurities in the alcohol or ether, probably in the latter, for with pure mercury and pure alcohol and ether, no scum is formed, and the mercury does not lose weight appreciably. They confirm Price's

statement as to low results in the determination of zinc, the cause being loss of both zinc and mercury on washing the amalgam with alcohol and ether. Copper amalgam, under similar conditions, does not lose in weight, and copper can be determined accurately with a mercury cathode.—A. S.

Zinc: Determination of — with the aid of the mercury cathode and rotating anode. L. G. Kollock and E. F. Smith. *Trans. Amer. Electrochem. Soc.*, 1908, **14**, 59—64.

The authors in opposition to Price (this J., 1907, 345) and others (see preceding abstract), maintain that zinc can be determined quite accurately by their method (this J., 1905, 1127) with a mercury cathode and rotating anode, provided the requisite precautions be taken. The method of working is described in minute detail.—A. S.

Nitric acid in liquids containing much organic matter; Use of nitron for the determination of —. H. Franzen and E. Lohmann. *J. prakt. Chem.*, 1909, **79**, 330—338.

The authors find nitric acid can be accurately determined by Busch's method by means of nitron (this J., 1905, 291), in solutions containing large quantities of organic matter, provided 2—2.5 c.c. of concentrated sulphuric acid be added for each 200 c.c. of solution. This addition of sulphuric acid prevents any co-precipitation of nitron oxalate and also the formation of a colloidal solution of nitron nitrate. When both nitric and nitrous acids are present, the latter may be oxidised to nitric acid by means of hydrogen peroxide, or it may be decomposed by means of hydrazine sulphate (*loc. cit.*)—A. S.

Perchlorate: Reduction and determination of —. V. Rothmund. *Z. anorg. Chem.*, 1909, **62**, 108—113.

ALTHOUGH reduction of the perchlorate ion cannot be brought about by the more common reducing agents, it is easily effected by the action of reduced salts of titanium, vanadium, and molybdenum, and reduction with titanous sulphate, $Ti_2(SO_4)_3$, in acid solution, furnishes a simple and accurate method of determining perchlorates. The solution, which may be prepared by the electrolytic reduction of titanous sulphate in sulphuric acid, should contain about 0.5 gram.-mol. of titanium and 2 gram.-mols. of sulphuric acid per litre, and, for every 0.1386 gram. of potassium perchlorate, 30 c.c. of this solution are used, together with 4 c.c. of strong sulphuric acid; the mixture is boiled for an hour in a stream of carbon dioxide, using a reflux condenser, and, after cooling, the excess of titanous salt is oxidised with permanganate, and the chlorine determined by Volhard's method. Since chlorates are reduced by titanous salts (this J., 1908, 434), it is easy to determine a perchlorate in the presence of a chlorate, as the latter is reduced also by ferrous sulphate and other common reducing agents.—F. Sopex.

ORGANIC—QUANTITATIVE.

Carbon in aliphatic hydroxy-compounds [cellulose in cuprammonium solution, &c.]; Determination of — in the wet way. E. Berl and A. G. Innes. *Ber.*, 1907, **42**, 1305—1309.

MOST hydroxy-compounds of the aliphatic series undergo complete combustion when treated with chromic acid in presence of concentrated sulphuric or phosphoric acid, and several methods for the quantitative measurement or weighing of the carbon dioxide produced have been proposed. The authors have standardised a gasometric method of procedure for the purpose of determining cellulose in cuprammonium solutions and have found the same to be of general application within certain limits. They prefer to use a very concentrated solution of pure phosphorus pentoxide as the dehydrating acid since sulphuric acid tends to give rise to secondary products. In certain cases, where combustion is difficult or incomplete, the addition of two drops of mercuric iodide is advantageous. The combustion flask has a short wide neck, fitted with a ground-in stopper carrying a tube which is connected to the top of a Bunte's burette. Into the side of the neck of the flask is fused a tap-funnel for the introduction of the acids. A quantity of substance, calculated to produce less gas than would be contained in the whole apparatus under atmospheric pressure, is weighed out into the flask, the connector is made, and the apparatus—flask and gas-burette—is completely evacuated. 5—6 c.c. of a saturated solution of chromic acid are introduced and then, after any action set up has subsided, 5—6 c.c. of concentrated phosphoric acid solution. The combustion is complete by heating for 10 minutes, and the gas is then expelled from the flask by admitting hot water through the funnel until it reaches the cork at the top of the burette. After cooling, the total volume of gas is measured by connecting the bottom of the burette with a pressure bottle containing saturated brine. The carbon dioxide is then absorbed by means of a concentrated solution of sodium hydroxide; this reagent is next removed and the volume again measured over brine. The difference between the two readings shows the volume of carbon dioxide produced which is corrected for the aqueous tension of brine ($\frac{1}{4}$ of that of pure water). The method affords results quite as concordant with the theoretical numbers as the method of dry combustion; it is not applicable to substances of the aromatic series, but it affords a ready means for the analysis of many technical products including carbohydrates and the salts of organic acids, citrates, tartrates, etc. When applied to solution of cellulose in cuprammonium solution, the liquid is weighed into the flask from a pipette, the ammonia expelled by heating gently, phosphoric acid is added and the gases due to by-products are driven off by heating *in vacuo*; the combustion is then effected as described.—J. XXIV.—SCIENTIFIC & TECHNICAL NOTES

Clays; Adsorption by —. P. Rohland. *Biochem. Zeits.*, 1909, **16**, 220—224.

ACCORDING to Michaelis and Rona (*Biochem. Zeits.*, 1907, **15**, 196), kaolins are good adsorbents for albumoses, and these workers consider that the adsorption of albumose by kaolin differs from the process of mechanical adsorption. According to the author, however, of all varieties of clays kaolins are least suitable for such experiments. He recommends dark-coloured, highly plastic clays which yield large quantities of colloidal hydroxides on contact

with water (see also this J., 1908, 900). Analyses of three such clays are quoted; these were found to contain considerable proportions of organic matter (probably also of a colloidal nature). These clays adsorb colloids, and some complex crystalloids such as dyestuffs (*loc. cit.*, 1908, 34). They adsorb the HCO_3^- and CO_3^{2-} ions completely from solutions of acid and normal carbonates respectively, and partially adsorb the PO_4^{3-} ion from primary phosphates; the adsorption of these ions is perhaps only a phenomenon accompanying the interchange of the alkalis of the salts with the calcium contained in the clay. The colloidal substances formed by contact of the clay with water present cellular structures of large surface area and therefore of high surface energy. The adsorption of colloidal solutions by coagulated substances depends on the property of substances in these two conditions, of uniting to form apparent compounds. It may be conjectured that the meshes of the coagulated cellular structure filled with water are too small to permit diffusion of the larger colloid molecules, but large enough to permit the passage of the smaller crystalloid molecules. Substances, such as dyestuffs, of complex molecular structure, are characterised by the property of becoming concentrated at the cellular surfaces. In all cases, the adsorption proceeds in such a manner that the hydroxides formed from the clay in contact with water, are first dissolved in the colloidal state, and are then coagulated by the presence, or by addition of electrolytes, thereby taking up, and retaining in their cellular structures, the substances to be adsorbed. These adsorptions by clays may also be regarded as special cases of the general rule that every substance that separates in the solid state (in these cases, in the coagulated state) from the surrounding solution, retains on its surface and in the layers immediately beneath, a larger or smaller portion of the other substance.—L. E.

Chemical action of light. XIV. G. Ciamician and P. Silber. *Ber.*, 1909, 42, 1386—1391.

UNDER the influence of light (2½ years' exposure) benzaldehyde yields benzoic acid, hydrobenzoin, and two polymericides of the formula, $(\text{C}_7\text{H}_6\text{O})_2$ (m. pt. 245° — 246° C.), and $(\text{C}_7\text{H}_6\text{O})_4$ (m. pt. 160° — 170° C.), respectively. The latter compound may have the constitution,

Exposure of a solution of dibenzylideneacetone in alcohol to light during a summer gave rise to a white compound of the formula, $\text{C}_{34}\text{H}_{30}\text{O}_2$, which melts at 125° — 135° C. Saffrol in the presence of a trace of iodine remained unchanged by light after a year's exposure, but isosaffrol yielded di-isosaffrol. Under similar conditions methyl-eugenol remained unchanged, whilst isomethyl-eugenol yielded a compound of the composition of di-isomethyl-eugenol as white needles, m. pt. 96° C., which is not identical with the compound described by Francesconi and Puxeddu as melting at 106° C. Mixtures of benzaldehyde and saffrol and isosaffrol respectively furnished in each case additive products of the formula, $\text{C}_7\text{H}_6\text{O}\cdot\text{C}_{10}\text{H}_{10}\text{O}_2$; that from saffrol melts at 150° — 180° C., whilst the one from isosaffrol melts at 170° — 180° C.—J. C. C.

Trade Report.

Chemical industry of France according to the data upon which the proposals for the new French customs tariff were based. *Chem. Ind.*, 1909, 32, 139—142. (See this J., 1909, 165.)

THE industry of heavy chemicals in France is, in general, in a satisfactory condition, and no essential alterations in the tariff are proposed. For bromine and bromides, crude and refined iodine, iodides and iodoform, white and red phosphorus, crystallised gallic, oxalic, phosphoric, and tannic acids, pure oxides of cobalt and lead, barium dioxide, calcined magnesia, potash from molasses, Vasec soda, caustic soda, sodium bicarbonate, sodium salts not otherwise mentioned, ammonia compounds, salts of

cobalt and silver, lead compounds, acetates, amyl alcohol, ammonium and potassium alums, calcined or ground alum-stone, arsenates, borax, chlorates, chlorides, chromates, chloroform, glycerin, kermes mineral, iron lactate, crude calcium acetate, sodium and potassium silicates, sulphates, quinine salts, sulphites and bisulphites, sodium thio-sulphate, potassium cyanide, chemical products from coal-tar, and chemical products not otherwise mentioned, it is proposed that the taxes levied according to the general tariff shall be 50 per cent. more than those of the present minimum tariff. In recent years it has become a general practice to separate the liquid fatty acids from linned oil and maize oil, and send these into France duty-free as "oleic acid," in order to escape the taxes on linned oil (6 fr. per 100 kilos.) and maize oil (12 fr. per 100 kilos.). From this cause the imports of "oleic acid" into France increased from 485,000 kilos. in 1892 to 4,287,000 kilos. in 1906, thus lessening the value of the oleic acid obtained in France as a by-product in the manufacture of stearine. It is therefore proposed to levy a tax of 1.5 fr. in the general tariff and 1 fr. in the minimum tariff on all liquid fatty acids, under the name "oleic acid." Also a tax of 15 fr. per 100 kilos. (general) and 10 fr. (minimum) on stearine is proposed.—A. S.

Patents Act procedure. *Times*, May 4, 1909.

THE Comptroller-General has issued orders amending the procedure under Section 27 of the Patents and Designs Act, 1907, and Patents Rules 78 to 81; these relate particularly to applications for revocation under Section 27, the object being to prevent frivolous and vexatious applications, which may be made merely to extract information as to competing concerns.

German chemical industry in 1908. *Times Eng. Suppl.*, May 5, 1909.

DURING April a number of the German chemical firms published their annual reports. In some cases the dividends declared are less than in previous years, and most of them complain that the past financial year has been an unsatisfactory one. The commercial crisis in America seriously affected the export of colours and chemical products to the United States, and in Japan and China the market has been disappointing. Recent political events in Turkey and in the Balkan States have also had a depressing effect upon the export trade. Reference is made in some of the reports to the stringent conditions of the new British patents law, and the hope is expressed that the German Government will act before the United States forms a similar law, and that it will arrange a reciprocal agreement. In the present year a slight improvement can be observed, and it is expected that normal conditions will soon be re-established.

New Books.

LABORATORIUMSBUCH FÜR DIE INDUSTRIE DER VERFLÜSSIGTEN UND KOMPRIMIERTEN GASE. VON DR. KARL URBAN. Wilhelm Knapp's Verlag, Halle a. S. 1909. Price M.80.

THIS forms Bd. VII. of the series of *Laboratoriumsbüchern für chemische und verwandte Industrie*. It is an 8vo volume containing 40 pages of subject matter with 24 illustrations, and the liquefied and compressed gases forming the subjects of attention throughout the book, are the following:—I. Liquefied ammonia. II. Liquefied chlorine. III. Liquefied carbon dioxide. IV. Liquefied sulphur dioxide. V. Compressed oxygen. VI. Compressed hydrogen. Of these, the chemical properties; physical constants; methods of preparation; apparatus used, etc., are given.

CHEMICAL INDUSTRY ON THE CONTINENT. A Report to the Electors to the Gartside Scholarships. By HAROLD BARON, B.Sc. The University Press, Manchester. 1909. Price 1s. net. Messrs. Sherratt and Hughes, 33, Soho Square, London, W.

8vo volume, containing 68 pages of subject matter, and an alphabetical index. The matter is divided amongst

ten chapters, in which the leading subjects respectively figure as follows:—I. Industrial development in Belgium. II. The Belgian textile industries. III. The chemical industries of Belgium. IV. Textile industries in Northern France. V. Chemical industries in Northern France. VI. Industrial development in Germany. VII. German chemical industries. VIII. A typical German colour works. IX. Dyeing in Western Germany. X. Patent protection.

INDUSTRIES DU PLOMB ET DU MERCURE. Par A. BOUCHONNET. *Tome premier*.—*Métallurgie. Tome second*.—Composés. Octave Doin et fils, 8, Place de l'Odéon, Paris. 1900. Price for Vols. I. and II., 10 frs.

VOL. I.—METALLURGY. Small 8vo volume, containing 287 pages of subject matter, and the alphabetical index. There are 37 illustrations. The work, divided into parts I. and II., treats of the metallurgy of lead in Part I., and of that of mercury in Part II. VOL. II.—COMPOUNDS. Contains 339 pages of subject matter, with 20 illustrations, and is also divided into two parts, Part I. being devoted to the compounds of lead, and Part II. to those of mercury. At the end of the volume (pp. 341 to 356), are (a), a bibliographic index; (b), the alphabetical index of subjects; and (c), a systematic table of contents.

75 JAHRE CHEMISCHER FORSCHUNG AN DER UNIVERSITÄT ZÜRICH. Festschrift zur Eröffnung des neuen Chemischen Instituts verfasst von den Studierenden der Chemie. Ernst Blätter, Bellerivestrasse, 66, Zürich, V. 1900. Price 4 frs., post free.

8vo volume, containing 100 pages of subject matter, and 15 illustrations. The matter consists of a historical description of the development of the chemical department of the University of Zürich, from its commencement in 1832 to the present date, with biographical sketches of the lives and careers of the chemical professors from Löwig, the first professor (1833), to Werner and Pfeiffer, the present professors. The report given of Werner's researches appears especially valuable. The biographies, with photo-engravings, of the following professors of chemistry are given, with descriptive reports of their research work, and dates of the same, with references:—C. J. Löwig (1833–1853); Edw. Schweizer (1852–1860); G. Städler (1853–1870); J. Wislicenus (1867–1872); Victor Merz (1869–1893); W. Weith (1871–1881); H. Abeljanz (1884 to date); Karl Schall (1883–1903); Alfred Werner (1893 to date); P. Pfeiffer (1908 to date).

Patent List.

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of Application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

- 10,027. Motion. *See under XVII.*
 10,095. British Thomson-Houston Co. (General Electric Co.). Production of high vacua. April 28.
 10,557. Yates. Steam-heating pipe coils and radiators for heating, drying, evaporating, &c. May 4.
 10,562. De Murrieta and Tully. Separating liquids from gases or vapours by centrifugal action. May 4.
 10,591. Aktiebolaget Swedish Nitric Synd. *See under VII.*
 10,771. Morgan Crucible Co., and Speirs. Crucibles. May 6.
 10,808. Fielding. *See under XVI.*
 11,030. Holle. Furnaces. May 10.

- 11,068. Pointon. Evaporation and drying of liquid compounds, &c. May 10.
 11,291. Ebbels, McOnie, and Jones. Filters. May 12.
 11,422. Eijduan. Evaporating apparatus.* May 14

COMPLETE SPECIFICATIONS ACCEPTED.

- 9283 (1908). Esping. Apparatus for raising liquid. May 5.
 11,088 (1908). Macfarlane. Evaporators for the concentration of liquids. May 19.
 12,078 (1908). Gray. High pressure digesters. May 12.
 16,405 (1908). Brooke, and Dempster and Sons. *See under II.*
 17,054 (1908). Peat. *See under X.*
 21,623 (1908). Brearley. Indicator for determining the temperature of heated objects. May 12.
 23,289 (1908). Fales and Baldwin. Apparatus for separating oil or other foreign substances from liquids. May 19.
 25,300 (1908). Boulton (Bradley). Centrifugal machine for separating solids from liquids. May 5.
 25,644 (1908). Tiemann. Apparatus for purifying solutions by settling. May 5.
 28,549 (1908). Schmatolla. *See under VII.*

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

- 10,219. Sonnenschein and Prager. Liquid for illuminating purposes. April 29.
 10,364. Hutchins. Gas plants. May 1.
 10,376. Hall. Incandescent mantles. May 1.
 10,482 and 10,484. Schniewind. Coke or like ovens.* May 3.
 10,486. Schniewind. Coking ovens, furnaces, &c.* May 3.
 10,745. Weickert. Mantles or incandescence bodies for gas lighting. [Addition to No. 2572 of 1908.*] May 6.
 10,765. Otto-Hilgenstock Coke-Oven Co. (Otto und Co.). Removing tar from the hot gases from coke ovens, gas retorts, &c., prior to recovering ammonia. [Addition to No. 12,809 of 1908.*] May 6.
 10,903. Mücke. Incandescent mantles. May 8.
 10,939. Perkins. Utilising anthracite slack or small for fuel. May 8.
 11,159. Richards. Carbonisation and distillation of fuel. May 11.
 11,218. Fielding. Gas producers.* May 12.
 11,254. Trachsler and Ernst. Manufacture of producer-gas. May 12.
 11,265. Gobbe. Gas producers. [Belg. Appl., May 16, 1908.]* May 12.
 11,315. Fisk. Incandescent gas mantles.* May 13.
 11,442. Gewerkschaft der Steinkohlenzeche Mont-Cenis. *See under VII.*
 11,527. Crossley and Rigby. Gas producers. May 15.

COMPLETE SPECIFICATIONS ACCEPTED.

- 6575 (1908). Von Bauer. Coke ovens. May 5.
 9150 (1908). Evans. *See under XXIII.*
 9377 (1908). Bantsart. Coke ovens. May 5.
 10,422 (1908). Rineker and Wolter. Obtaining gas from tar in gas-producer plant. May 12.
 14,942 (1908). Westinghouse Metal Filament Lamp Co. (Westinghouse Metallfaden Glühlampenfabr.). Production of tungsten filaments for electric incandescence lamps. May 12.
 16,405 (1908). Brooke, and Dempster and Sons. Vertical retorts. May 19.
 19,928 (1908). Barth. Manufacture of fuel for internal-combustion engines. May 5.
 20,014 (1908). Lake (Internat. Gas Development Co.). Manufacture of gas. May 12.
 21,489 (1908). Gennotte. Gas retorts. May 5.
 25,854 (1908). Siemens und Halske A.-G. Manufacture of electric incandescence filaments from tungsten or other difficultly fusible metal. May 12.
 1332 (1909). Kuzel. Metal filaments for electric lamps. May 19.

- 2853 (1909). Siemens und Halske A.-G. Manufacture of electric incandescence filaments from tungsten. May 12.
 3951 (1909). British Thomson-Houston Co. (General Electric Co.). Manufacture of incandescent electric lamp filaments. May 12.
 6845 (1909). Von Bauer. Coke ovens. May 5.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

APPLICATIONS.

- 10,969. Wallace and Reynaud. Destructive distillation of vegetable substances and resins. May 8.
 11,359. Karno and Naka. Method of freeing petroleum oil from smoke-producing elements.* May 13.

COMPLETE SPECIFICATIONS ACCEPTED.

- 10,892 (1908). Seidenschneur. Method and apparatus for distilling crude petroleum. May 19.
 17,054 (1908). Peat. *See under X.*

IV.—COLOURING MATTERS AND DYESTUFFS.

APPLICATIONS.

9888. Johnson (Badische Anilin und Soda Fabrik). Manufacture and employment of anthracene colouring matters. April 26.
 9908. Newton (Bayer und Co.). Manufacture of a new dyestuff. April 26.
 10,187. Cassella und Co. Manufacture of red chromable dyestuffs. [Addition to No. 8154 of 1909. Fr. Appl. May 26, 1908.]* April 29.
 10,461 and 10,462. Newton (Bayer und Co.). Manufacture of azo dyestuffs. May 3.
 10,463. Newton (Bayer und Co.). Manufacture of anthracene compounds. May 3.
 10,666. Ges. f. Chem. Ind. in Basel. Manufacture of green vat dyestuffs. [Ger. Appl. May 11, 1908.]* May 5.
 10,936. Inray (Soc. Chem. Ind. in Basle). Manufacture of substantive azo dyestuffs.* May 8.
 11,253. Newton (Bayer und Co.). Manufacture of azo dyestuffs and process of developing them on the fibre. May 12.
 11,355. Newton (Bayer und Co.). Manufacture of azo dyestuffs and process of developing them on the fibre. May 13.
 11,356. Newton (Bayer und Co.). Manufacture of azo dyestuffs. May 13.
 11,364. Act.-Ges. f. Anilinfabr. Manufacture of blue substantive dyestuffs. [Ger. Appl. May 26, 1908.]* May 13.

COMPLETE SPECIFICATIONS ACCEPTED.

- 10,387 (1908). Newton (Bayer und Co.). Manufacture of derivatives of the anthracene group. May 12.
 12,877 (1908). Fowler and O'Meara. *See under III.B.*
 15,463 (1908). Soc. pour l'Ind. Chim. à Bâle. Manufacture of *p*-amidophenyl-2-azimido-5-naphtholsulphonic acid and dyestuffs therefrom. May 5.
 17,352 (1908). Ransford (Cassella und Co.). Manufacture of sulphide colours. May 19.
 18,107 (1908). Newton (Bayer und Co.). Manufacture of anthracene derivatives. May 12.
 20,802 (1908). Bloxam (Act.-Ges. f. Anilinfabr.). Manufacture of sulphurised dyestuffs. May 19.
 3602 (1909). Meister, Lucius, und Brünig. Manufacture of dyestuffs. May 5.

V.—PREPARING, BLEACHING, DYEING, RINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

APPLICATIONS.

9840. Sumner. Manufacture of elastic non-inflammable coir fibre. April 26.

9868. Turner. Hawking machines* employed in indigo dye-vats. April 26.*

9920. Dreaper. Manufacture of artificial silk. April 27.
 10,189. Johnson (Badische Anilin und Soda Fabrik). Production of brown shades on fibrous material with or without discharge effects. [Addition to No. 17,241 of 1905.] April 29.

- 10,190. Johnson (Badische Anilin und Soda Fabrik). Printing or dyeing on fibrous material. [Addition to No. 17,241 of 1905.] April 29.

- 10,200. Védie. Ensuring uniformity of colour in fabrics. April 29.

- 10,460. Pinkus. Increasing the durability of animal tissues.* May 3.

- 10,604. Opfermann, Friedemann, and A.-G. f. Maschinenpapier. Treating prepared wood-cellulose to produce artificial threads and nitrocellulose. [Ger. Appl. April 15, 1909.]* May 4.

- 10,609. Lake (Empire Duplex Gin Co.). Treatment of cotton, &c. May 4.

- 10,795. May and Grosvenor. *See under XIX.*

- 11,024. Hoffman and Decoster. Rapid impregnation of vegetable fibres in the cold.* May 10.

- 11,253. Newton (Bayer und Co.). *See under IV.*

- 11,354. Newton (Bayer und Co.). Production of new threads. May 13.

- 11,355. Newton (Bayer und Co.). *See under IV.*

COMPLETE SPECIFICATIONS ACCEPTED.

- 4586 (1908). Brintons, Ltd., and Osborn. Apparatus for dyeing, washing, or bleaching yarns and slubbing. May 12.

- 7201 (1908). Caberti, and Manifattura E. Stamperia Lombarda. Printing on textile fabrics. May 12.

- 9651 (1908). Newton (Bayer und Co.). Fixation of dyestuffs on fibre. May 12.

- 10,289 (1908). Boulton (Jefferson). Bleaching and treating cloth, warp, or other textile materials with liquids. May 19.

- 10,316 (1908). Hoinkes. Treatment of textile fabrics. May 19.

- 12,913 (1908). Worner. Centrifugal drum apparatus for dyeing, &c. May 19.

- 13,760 (1908). Khig. Process and apparatus for drying textile and other materials. May 19.

- 21,840 (1908). Verein. Kunstseidefabr. Making multi-coloured surfaces. May 5.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

APPLICATIONS.

- 10,170. Jahn and Grünhut. Dyeing, impregnation, or proofing of wood. April 29.

- 10,716. Gordon. Printing in natural colours on paper, cardboard, wood, ivory, or porcelain. May 6.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

9918. Walker. *See under X.*

- 10,164. Price. Manufacture of nitrous and nitric acids, nitrate, nitrite, or sulphonitrate or nitrite of lime, soda, or potash. April 29.

- 10,171. Nathan, Thomson, and Thomson. Manufacture of nitric acid. April 29.

- 10,465. Johnson (Badische Anilin und Soda Fabrik). Absorption of oxides of nitrogen. May 3.

- 10,517. Internat. Salt Co., and Tee. Manufacture of salt. May 4.

- 10,591. Aktiebolaget Swedish Nitric Synd. Process and apparatus for concentrating acids. [Swed. Appl. May 6, 1909.]* May 4.

- 10,592. Aktiebolaget Swedish Nitric Synd. Concentration of nitric acid. [Swed. Appl. May 6, 1908.]* May 4.

- 10,774. Grimm. Sulphur burners.* May 6.

- 10,867. Johnson (Badische Anilin und Soda Fabrik). Production of commercially pure nitrates. May 7.

- 11,073. Dewey. *See under X.*
 11,123. Friedrich et Cie. Preparation of sodium sulphite and ammonium chloride. [Ger. Appl., June 20, 1908.]* May 11.
 11,128. Moritz. Apparatus for making sulphuric acid. [Fr. Appl., Oct. 26, 1908.]* May 11.
 11,274. Johnson (Badische Anilin und Soda Fabrik). Manufacture of nitrates. May 12.
 11,275. Johnson (Badische Anilin und Soda Fabrik). Manufacture of calcium nitrite. May 12.
 11,332. Hannan. Manufacture of oxygen and hydrogen or other gases. May 13.
 11,442. Gewerkschaft der Steinkohlenzeche Mont-Cenis. Manufacture of ammonium sulphate from distillation gases. [Ger. Appl., May 15, 1908.]* May 14.
 11,525 and 11,526. Pope. *See under XIII.A.*

COMPLETE SPECIFICATIONS ACCEPTED.

- 26,981 (1907). Ramsay. Recovery of oxides of nitrogen from air or other gases. May 5.
 13,207 (1908). Mond Nickel Co., Hirtz, and Cowap. Manufacture of cobalt compounds and their application. May 12.
 19,148 (1908). Pipereaut and Vila. Preparation of metal sulphides and alkali hydrosulphites from ores and other metallic compounds. May 12.
 23,917 (1908). Millet and Mussi. Alimentary ferruginous salt. May 12.
 28,549 (1908). Schmatolla. Kilns for burning limestone, dolomite, &c. May 12.
 596 (1909). Williams. Extraction of sulphur from spent oxide or like material. May 12.
 1150 (1909). Gruner. Sodium peroxide composition for washing and bleaching purposes. May 12.

VIII.—GLASS, POTTERY, AND ENAMELS.

APPLICATIONS.

9853. Sievert. Glass-making apparatus.* April 26.
 9926. Redfern and Sharratt. Printing on pottery. April 27.
 11,414. West and Lewis. Kilns or ovens for firing bricks, tiles, china, &c. May 14.

COMPLETE SPECIFICATIONS ACCEPTED.

- 13,179 (1908). Salamon, and Exploration Co. Preparation of china clay. May 12.
 25,042 (1908). Sievert. Manufacture of glass plates. May 5.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

- 10,170. Jahn and Grünhut. *See under VI.*
 11,184. Pavin de Lafarge. Manufacture of cement. [Fr. Appl., June 13, 1908.]* May 11.
 11,414. West and Lewis. *See under VIII.*

X.—METALS AND METALLURGY.

APPLICATIONS.

9918. Walker. Reverberatory furnaces for producing blister copper and sulphuric acid. April 27.
 9955. Brand. Extraction of zinc. April 27.
 9958. Wildbore (Haggenmiller). Smelting pyritic and other sulphide ores.* April 27.
 10,029. Muirhead. Open hearth steel-making furnaces for producing higher grade steels and other alloys. April 28.
 10,224. Molengraaff, Caron, and Keen. Separation of gold from ores, sands, gravels, &c. April 30.
 10,352. Göpfert. Recovery of copper from waste liquors produced in pickling metals. May 1.
 10,381. Simon. Separation of metals or minerals from gangue. May 1.
 10,515. Jackson. Blast furnaces. May 4.

10,615. Matthews and Pim. Treatment of iron and steel. May 5.

10,657. Ruthenburg. Preparation of zinc and other volatile metals from their ores. May 5.

10,658. Ruthenburg. Preparation of zinc oxide for smelting, &c. May 5.

10,790. Simpson and Oviatt. Direct production of iron and steel from oxides of iron. May 6.

10,947 and 10,948. Moeller (Rosalt). Extraction of metals from their ores by a wet process. May 8.

10,952. Simpson and Oviatt. Direct production of iron and steel from oxides of iron. May 8.

10,995. Cowper-Coles. Extraction of iron from its ores. May 10.

11,044. Cox. Concentrating apparatus for separating metals, ores, &c., in wet recovery processes. May 10.

11,073. Dewey. Treatment of arsenide ores and compounds.* May 10.

11,263. Pezzolato. Treatment of pyrites ashes.* May 12.

11,376. Ebbw Vale Steel, Iron and Coal Co., and others. Treatment of spathic and other ores for use in blast furnaces. May 13.

COMPLETE SPECIFICATIONS ACCEPTED.

- 12,042 (1908). Duke. Metallic alloys. May 12.
 14,093 (1908). Baraduc-Muller. Metallurgical process for obtaining alloys and steels containing silicon. May 12.
 15,176 (1908). Loiseau. Manufacture of zinc. May 19.
 17,054 (1908). Peat. Apparatus for subjecting ores, shale, coal &c., to the action of heat, especially for treating iron ore or ironstone shale. May 5.
 17,610 (1908). Siemens und Halske A.-G. Increasing the ductility of tungsten. May 5.
 19,148 (1908). Pipereaut and Vila. *See under VII.*
 23,068 (1908). Higgins. Recovery of tin from tin scrap. May 5.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

- 10,655. Cowper-Coles. Electrodeposition of iron. May 5.
 10,791. Schauli. Electrolyte for galvanic batteries applicable also as an emulsion for photographic negative and as an electrolytic resistance for electric currents. May 6.
 10,834. Fahn. Depolarisers of galvanic batteries. May 7.
 10,911. Niblett. Electrolytic apparatus. May 8.
 11,060. Johnson (Chem. Fabr. Griesheim-Elektron). Production and maintenance of long electric arcs. May 10.
 11,166. Diesser. *See under XIII.B.*
 11,317. Rooper and Belcher. Electric furnaces. May 11.
 11,480. Hiorth and Söderberg. Electric induction furnaces. [Appl. in Norway, May 16, 1908.]* May 11.

COMPLETE SPECIFICATIONS ACCEPTED.

- 16,885 (1908). Lake (Standard Varnish Works). Soluble electric insulating compounds. May 12.
 28,276 (1908). Voelker. Electric furnaces. May 12.
 6267 (1909). Steinert and Stein. Apparatus for electric magnetic separation. May 5.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

APPLICATIONS.

- 10,075. Newton (Bayer und Co.). Medicinal soap. April 28.
 10,616. Dörner. *See under XIV.*

COMPLETE SPECIFICATIONS ACCEPTED.

- 9758* (1908). Barbé, Garelli, and De Paoli. Saponification of fatty materials by means of ammonia. May 11.
 11,597 (1908). Fischer. Production of lecithin, fat oil, and cholesterolin. May 19.

- 23,698 (1908). Boulton (Fischer). Apparatus for use in manufacturing soap. May 12.
 24,836 (1908). Barbé, Garelli, and De Paoli. Separation of solid from liquid fatty acids. May 12.
 24,837 (1908). Barbé, Garelli, and De Paoli. Transformation of liquid into solid fatty acids. May 12.
 24,838 (1908). Barbé, Garelli, and De Paoli. Obtaining soda and potash soaps from ammonia soaps. May 12.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES INDIA-RUBBER, &c.

(A.)—PIGMENTS, PAINTS.

APPLICATIONS.

- 10,073. Newton (Bayer und Co.). Preservative preparations. April 28.
 11,525. Pope. Manufacture of white lead. May 15.
 11,526. Pope. Manufacture of lead oxide and preparing it for conversion into red lead or other lead compounds. May 15.

COMPLETE SPECIFICATION ACCEPTED.

- 16,520 (1908). Hughes. Manufacture of sublimed white lead. May 12.

(B.)—RESINS, VARNISHES.

APPLICATIONS.

- 10,969. Wallace and Reynaud. *See under III.*
 11,166. Diesser. Substances to be used as varnishes and for impregnation and insulation. [Comprised in No. 16,737, Aug. 8, 1908.]* May 11.

COMPLETE SPECIFICATION ACCEPTED.

- 12,877 (1908). Fowler and O'Meara. Extraction of lac-dye and shellac. May 5.

(C.)—INDIA-RUBBER.

APPLICATIONS.

- 10,267. Howard (Evans and Lister). Rubber substitute. April 30.
 10,537. Wheatley. Manufacture of indiarubber substitutes. May 4.
 10,956. Wallace and Reynaud. Synthetic production of indiarubber. May 8.
 10,972. Wallace and Reynaud. Treatment of isoprene. May 8.

COMPLETE SPECIFICATIONS ACCEPTED.

- 11,949 (1908). D'Alòe. Indiarubber compound. May 19.
 14,859 (1908). Rutgerswerke A.-G. Manufacture of filling compositions for addition to rubber and other gums. May 19.
 20,896 (1908). Flamant and Worms. Separating rubber from resin in latex and resinous products. May 5.

XIV.—TANNING, LEATHER, GLUE, SIZE, &c.

APPLICATIONS.

- 10,616. Dörner. Extraction of glue and fats from bones and skins. May 5.
 10,661. Spigno. Solutions for treating leather, skins, and hides. May 5.
 10,667. Spigno. Treatment of tanned hides and skins. May 5.

COMPLETE SPECIFICATIONS ACCEPTED.

- 9652 (1908). Mills (Harrington Co.). Size composition. May 12.
 10,201 (1908). Reddan. Material of the nature of leather and method of manufacturing same from hides. May 19.
 2504 (1909). Mackay. Leather product and process of making same. May 12.

XV.—MANURES, &c.

COMPLETE SPECIFICATIONS ACCEPTED.

- 11,644 (1908). Harrison. Manufacture of fertilisers. May 5.
 21,590 (1908). Carlson. Production of fertilisers. May 12.
 25,958 (1908). Soc. Gen. des Engrais Organiques. Conversion of refuse and sewage into manure. May 19.

XVI.—SUGAR, STARCH, GUM, &c.

APPLICATION.

- 10,808. Fielding. Means for drying starch and similar substances. May 7.

XVII.—BREWING, WINES, SPIRITS, &c.

APPLICATIONS.

- 10,027. Motion. Apparatus for drying brewers' draff and other material. April 28.
 10,458. Braasch. Production of yeast. [Ger. Appl., May 5, 1908.]* May 3.
 10,671. Dand, and Sharpe and Co. Treatment of beers. May 5.
 11,277. Allen. Treatment of beer and other fermented liquors.* May 12.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; AND DISINFECTANTS.

(A.)—FOODS.

APPLICATIONS.

9883. Girard. Cereal foods and the manufacture thereof.* April 26.
 10,033. Bathgate. Bread-making flour. April 28.
 10,277. Henri, Helbronner, and von Reeklinghausen. Treatment of foods and other products which undergo fermentation. April 30.
 10,445. Mislin. Utilisation of the waste product of milled or ground cereals.* May 3.

COMPLETE SPECIFICATIONS ACCEPTED.

- 5133 (1908). Frye. Production of a solid from milk. May 12.
 23,183 (1908). Boulton (Electric Meat Curing Co.). Curing process. May 19.

(B.)—SANITATION; WATER PURIFICATION.

APPLICATIONS.

- 10,261. Spencer. Materials for purifying air. April 30.
 11,421. Eijdsman. Treatment of sea water.* May 14.
 11,471. Didelon and Braut. Apparatus for rendering soluble and nitrifying sewage and other waste. [Fr. Appl., June 29, 1908.]* May 14.

COMPLETE SPECIFICATION ACCEPTED.

- 25,958 (1908). Soc. Gen. des Engrais Organiques. *See under XV.*

XIX.—PAPER, PASTEBOARD, &c.

APPLICATIONS.

9813. Horsfield and Horsfield. Manufacture of wall-paper. April 26.
 9968. Beck. Apparatus for making half-stuff from peat, turf, or other fibrous material.* April 27.
 10,604. Opfermann and others. *See under V.*
 10,795. May and Grosvenor. Apparatus for coating and drying paper, cloth, &c.* May 6.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

APPLICATIONS.

- 10,074. Newton (Bayer und Co.). Manufacture of pharmaceutical compounds. April 28.

11,108. Wellcome and Pyman. Manufacture of therapeutic compounds. [Addition to No. 314 of 1909.] May 11.

11,109. Wellcome and Barger. Manufacture of therapeutic compounds. [Addition to No. 1560 of 1909.] May 11.

11,110. Wellcome and Barger. Synthesis of physiologically active bases. [Addition to No. 1561 of 1909.] May 11.

COMPLETE SPECIFICATIONS ACCEPTED.

11,597 (1908). Fischer. *See under XII.*

17,132 (1908). Newton (Bayer and Co.). Manufacture of therapeutic compounds. May 12.

22,167 (1908). Gehe and Co., A.-G., and Fey. Dry preparation of cod-liver oil and malt extract. May 19.

24,836 and 24,837 (1908). Barbé and others. *See under XII.*

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATIONS.

9900. Wilson. Photographic emulsions of silver phosphate. April 26.

9925. O'Brien (Thornton). Photographic films. April 27.

10,059. Weigert-Sterne. Colour photography. April 2.

10,284. Wilson. Photographic emulsions. April 30.

10,611. Berthon. Three-colour photographic processes. May 4.

10,791. Schauli. *See under XI.*

COMPLETE SPECIFICATIONS ACCEPTED.

8919 (1908). Merkel. Colour photography. May 5.

9044 and 9693 (1908). Whitfield. Manufacture of colour screens for colour photography. May 5.

XXII. EXPLOSIVES, MATCHES, &c.

APPLICATIONS.

9992. Schmitz. Manufacture of igniting compositions. April 27.

11,179. Bowen. Explosives. May 11.

XXIII. GENERAL ANALYTICAL CHEMISTRY.

COMPLETE SPECIFICATIONS ACCEPTED.

9150 (1908). Evans. Apparatus for measuring and indicating the explosive and calorific values of gaseous mixtures. May 5.

9726 (1908). Weiss. Estimation of uric acid in urine. May 12.

Journal of the Society of Chemical Industry.

No. 11, Vol. XXVIII.

JUNE 15, 1909.

No. 11, Vol. XXVIII.

PROCEEDINGS

OF THE

TWENTY-EIGHTH ANNUAL MEETING.

LONDON.

WEDNESDAY, MAY 26TH, 1909.

The twenty-eighth Annual General Meeting of the Society was held in the Jehanghier Hall, Imperial Institute, South Kensington, on Wednesday, May 26th, the President, Prof. R. Meldola, F.R.S., in the chair.

The Minutes of the last meeting were read and confirmed.

On the motion of Sir Robert Pullar, seconded by Dr. Hugo Müller, F.R.S., Messrs. C. D. McCourt and E. Linder were appointed scrutators of the ballot.

The PRESIDENT then declared the ballot closed.

The SECRETARY (Mr. C. G. Cresswell) then read the Report of the Council, as follows:—

REPORT OF COUNCIL.

The number of members on the register is 4,323 as compared with 4,520 at the last Annual Meeting. During the ten months 258 members have been elected as compared with 270 last year, and the losses have been 455 as against 269. This loss is due to the provisions of By-law 12, which allow less latitude than the old By-law to members who do not pay their subscriptions within the specified time. There were 40 deaths as compared with 47 last year.

The names of the members removed by death are: Dr. Jas. Baynes, Alex. Bottle, Harold G. S. Brown, O. F. T. Carlsson, J. Trevor Cart, A. V. Cunningham, J. K. Field, S. P. Franchot, Sir J. Christopher Gamble, J. C. Garnauss, Holbrook Gaskell, Dr. George Gore, W. J. W. Gunther, W. M. Habirshaw, W. H. Hacking, R. H. Harland, Dr. H. A. Hunieke, Jas. S. Hutton, R. V. Jackson, Paul Jantzen, S. H. Johnson, John A. Just, R. Lucas, C. F. McCombie, S. Mellor, Charles Mook, Harry Nicholson, Standen Paine, G. H. Parker, Dr. E. Plath, T. Horne Redwood, W. P. Rix, J. W. Spencer, S. J. Steel, Sir Thomas Stevenson, J. F. Swanson, Howard Ward, Sir Thomas Wardle, H. D. Warren, and A. Zumbeck.

Eight candidates having been nominated to fill four vacancies among the ordinary Members of Council, a ballot is required on this occasion. In accordance with the provisions of By-law 26, the names of the Hon. Treasurer, Hon. Foreign Secretary, and Auditors are set forth on the Ballot paper.

Under By-law 38, the Council may make Regulations, subject to approval by an Annual General Meeting, and, accordingly, Regulations dealing with the subscriptions and entrance fees of Members, the procedure of the Annual General Meeting, the expenditure of the Society's funds by Committees, and the elections of Local Sections will be submitted to this meeting for approval. These Regulations merely continue the procedure set forth in the By-laws of the Society of 1881.

Standing Orders for regulating the proceedings of the Council, and Rules for the Guidance of the Publication Committee, Officers, and others in the production of the Journal are also in course of preparation.

A General Purposes Committee has been formed for consultative and advisory purposes, especially in regard to finance and investments.

By-law 58 gives the option of investing the Society's funds either in the names of Trustees or in the name of the Society. The latter alternative has been chosen, and the securities have now been transferred from the names of Dr. George Beilby and Mr. David Howard, the surviving Trustees, to the name of the Society. The hearty thanks of the members are due to the Trustees

for their long and arduous services, and to Mr. S. Godfrey Hall, as an executor of the late Hon. Treasurer and Trustee, Mr. Samuel Hall, for the assistance he has rendered.

The Hon. Treasurer will lay his financial report before the meeting.

Among the items of extraordinary expenditure during the past year appears the Decennial Index, the total cost of which has been about £3,000. Three thousand copies have been printed, and the sale price for each copy, exclusive of postage, has been fixed at ten shillings, so that if every copy were sold, the charge upon the funds of the Society would be £1,500. So far, only some 1,200 copies have been sold, though it is hoped that, as more members realise its value, some further sales will be made. Serious consideration will be necessary before another Decennial Index is undertaken.

Dr. Charles E. Fawsitt has resigned his post as Hon. Secretary of the Scottish Section on his acceptance of the post of Professor of Chemistry at the University of Sydney, N.S.W., in succession to Prof. A. Liversidge, F.R.S. The meeting will surely wish to be associated with the vote of thanks accorded by the Council to Dr. Fawsitt for his services, and to congratulate him on his appointment.

Mr. Thomas Tyrer has retired, by seniority, from his position as representative of the Society on the Board of the National Physical Laboratory, and Mr. Walter F. Reid has been elected in his place.

Messrs. Wm. Burton, J. T. Dunn, Noel Heaton, Douglas Herman, Walter F. Reid, and W. P. Rix have been appointed to serve on a joint committee promoted by the English Ceramic Society to consider questions connected with refractory materials of all kinds.

Messrs. J. E. Stead and G. T. Holloway have been appointed to represent the Society at a Congress at Copenhagen promoted by the International Association for Testing Materials.

The Council trusts that the Members of this Society will do all in their power to render the International Congress of Applied Chemistry a success, by attending the meetings and taking part in the proceedings.

Mr. R. FORBES CARPENTER moved the adoption of the Report. Some very distinguished men had been removed by death, including Mr. Holbrook Gaskell, Dr. George Gore, Sir Thomas Stevenson, and Sir Thomas Wardle. The Decennial Index was a most valuable addition to the Journal, and it was to be hoped that those who valued the Index would make its benefits still further known: in fact, no member who wished to make good use of the Journal could dispense with it. After referring to the retirement of Mr. Tyrer from his position as representative on the Board of the National Physical Laboratory, he said they might congratulate themselves on the choice of a successor, for Mr. Reid was one of the earliest to draw the attention of the Society to this very important matter, and it was a letter from him to Lord Rayleigh which induced the Royal Society to appoint two representatives from that Society on the Board.

Prof. A. LIVERSIDGE, in seconding the motion, said they were deeply indebted to the Council for the work they had done.

The motion was put, and carried unanimously.

Report of Honorary Treasurer.

The HON. TREASURER (Mr. Thomas Tyrer) drew attention to the slight deficit, as shown by the Balance Sheet, of £183 1s. 1d., which was the total deficit after every possible liability had been settled, and after defraying the cost of the Decennial Index, which was very heavy. In the year 1908 they paid under that heading £1,064 2s. 8d., and the year before £680; the sales in the two years amounted to £180 and £170 respectively, which was not very satisfactory. Speaking as a manufacturer, he would not be without it if it cost five times the money; in fact, it was an absolute necessity

THE SOCIETY OF CHEMICAL INDUSTRY.

to any manufacturer or technical man. In addition, the expenditure involved by the Charter had amounted to £372 12s. 8d. during 1908, and in the previous year £332. Had it not been for those two extraordinary items of expenditure, which would not occur again, there would have been a considerable surplus on the year's working. The average surplus of late years had been something like £350 or £360, and he had no doubt that could be maintained by judicious management. He also called attention to the value of their investments, which this year appeared as £15,590, as against £16,554 last year, owing to the depreciation in securities. The present auditors thought that, although the dividends were practically the same, the actual value at which the Stocks could be realised at the date at which the Accounts were made up should appear in the Balance Sheet, an opinion which he thought the members would endorse. He had only to add that these deficiencies were really only apparent.

Mr. A. C. CHAPMAN moved the adoption of the Report of the Honorary Treasurer. Apart from the fact that the expenditure exceeded the income during the past year, but only to a small amount, and bearing in mind the extraordinary expenditure incurred, they must all agree that the Statement was exceedingly satisfactory, and for that they were indebted in no small degree to the services of the Honorary Treasurer. They all thoroughly appreciated the great services he had rendered, and was

rendering to the Society. He, therefore, in moving the adoption of the Report also moved that their heart thanks be given to the Honorary Treasurer for the service he had so admirably and so ungrudgingly rendered.

Dr. HUGO ERDMANN seconded the motion, which was carried unanimously.

Mr. TYLER said he highly appreciated the good feeling of his fellow members. He believed in the Society and therefore he worked for it, but they wanted it to increase and although it never was in a better position for exercising the great benefits which it did for this and other countries still every member ought to be a missionary, and endeavor to obtain more members.

President's Address.

EDUCATION AND RESEARCH IN APPLIED CHEMISTRY.

By RAFAEL MELDOLA, F.R.S.

It is the privilege of the occupant of the Presidential Chair of the Society of Chemical Industry to address the members on a subject of his own choice, and, in the case of Presidents who are or have been actively engaged in some branch of chemical industry, it is only natural to expect that there should be from this chair an author

We have examined the foregoing Income and Expenditure Account for the year 1908, and Balance Sheet, dated 31st December, 1908, and have verified the Investments and the balance at the Bankers. In our opinion the accounts correctly show the position of the Society at 31st December, 1908.

9, Old Jewry Chambers, London,

Chartered Accountants.

live pronouncement concerning that branch of the industry of which he is the representative. But it has so been the custom in this Society for the Presidency to be held both by men identified with the industrial side of chemistry and by those representative of its purely scientific and academic side. If, on the present occasion, I venture to express the opinion that this custom is a wise one, it is for no personal reasons, but because its recognition by our Society proclaims publicly that principle which it has been one of the main objects of my life to uphold—the interdependence of Science and Industry. In which capacity I have been called upon to discharge the honourable duties of this office it is not for me to decide. I can lay claim to have had some direct experience in manufacturing chemistry, but for nearly a quarter of a century my duties as a Professor have made me responsible for the training of students who have entered the technical College at Finsbury presumably with the object of becoming industrial chemists, and I shall therefore be only following the example of my predecessors in selecting as the subject for an address that topic with which my later occupation has made me most familiar, viz., the educational side of industrial chemistry. It may be useful, by way of prelude, to indicate some of the reasons why it appears to me necessary for this Society to make its voice heard just now in the educational world. We have already made some incursions into this main. The subject has occasionally been dealt with by Sectional Chairmen, and in 1899 the President of the Society, Dr. G. Beilby, gave a most valuable address on "The Relations of the Society to Chemical Engineering and to Industrial Research"—an address of especial significance as coming from a technologist who has interested himself in the educational side of the subject. A decade

has elapsed since the delivery of that address and now the question of the training of industrial chemists has again been raised. The question is by no means a new one—it has been slumbering for some years—but it is only recently that it has taken the more definite form of whether our Universities should develop schools of applied chemistry. The subject has aroused great interest all over the country and discussions have been held under the auspices of our Sections at Birmingham, Manchester, and Liverpool. I may add also that the question has had to be faced in connection with the proposed University at Bristol. The topic is in fact "in the air," and as appears to be admitted on all sides, there is no better organisation for giving scope to free interchange of opinions than our own Society.

How far the question has affected the older Universities will appear from the circumstance that six years ago I was invited to address the University Extension meeting at Oxford on the relations between scientific research and chemical industry.* It is evident to me that we cannot afford to shut our eyes to these signs of the times. If any criticism is to be applied to the earlier attempts to deal with this problem, it is that they have hitherto taken the form of isolated expressions of views by manufacturers or teachers; there has been no organised conference and no practical result has followed. Once more in the history of technical education in our subject, the manufacturers and the teachers have been brought face to face, and the recent Sectional discussions, if not leading to the development of any coherent scheme, cannot have failed to clear the air by enabling the two parties chiefly

* See "Nature," Aug. 27th, 1903.

concerned to realise more precisely the nature of the problem and the points of agreement or disagreement between them.

The question from the University standpoint appears to have been mooted at Birmingham in 1907 by Sir Oliver Lodge, and Professor Kipping's address last year to the Chemical Section of the British Association at Dublin is evidently largely responsible for the renewed discussions in the provinces. I may remind you also that last February Dr. Beilby again dealt with the subject from the point of view of the Technical Schools in his address to the Association of Technical Institutions.* Our former President, Mr. William H. Nichols, has likewise placed upon record some valuable observations and suggestions respecting the college-trained chemist, which, although necessarily concerned with the state of affairs in America, may be profitably read by our members on this side of the Atlantic.†

The Society of Chemical Industry in relation to Technical Education.

Among the many special reasons which may be adduced in support of the contention that the training of industrial chemists is one of the most pressing questions now before the country both from the point of view of industry and of education, I would in the first place invite a comparison between the chemical manufacturers and the representatives of other branches of applied science, more especially the engineering industries. It must, I think, be conceded that, with respect to this latter department of technical education, there has been much more coherence and solidarity—a very much keener personal interest on the part of the leaders of the profession than has been shown by the chemical manufacturers. Of course we all know of notable exceptions in our own industry, and it may not be invidious to mention in this connection the activity of Dr. Beilby in Glasgow and of Mr. Levinstein in Manchester. The suggestive paper by Mr. Oscar Guttman on "The Works Chemist as Engineer," read before our London Section in 1907, may also be regarded as a contribution to the educational side of our work.

But these cases are exceptional, and on the whole it cannot be said that our manufacturers have helped to organise the modern educational policy in this country to anything approaching the same degree as have the engineers. The practical effect of this neglect is that the term technical education in Great Britain has become almost synonymous with training in engineering, either civil, mechanical, or electrical, and on the committees and governing bodies of all the newer institutions the engineering influence is, as a consequence, the predominating influence. From the point of view of the engineering prosperity of our country this is no doubt a matter for congratulation, and I cannot help thinking that chemical industry would have been materially helped if our manufacturers as a class had taken an equally active share with respect to the educational requirements for their own occupation. At any rate, this Society is, *par excellence*, the tribunal to which the present state of affairs respecting the training of chemical technologists can be most appropriately submitted. I may remind you in this connection that we are the only chemical organisation in the country which has been given a direct voice in framing the educational policy of the Imperial College of Science and Technology by our having the right to nominate a representative on the governing body of that institution.

Another reason for directing attention to the relations between this Society and the teaching profession at the present juncture is that the lack of active interest in the educational side of applied chemistry on the part of the manufacturers has acted detrimentally to their own cause. Perhaps I may venture on this occasion to claim to be in some measure a representative of both parties, and from actual experience I know full well that the

teachers, if left severely alone by the manufacturers, are apt to become too purely bookish, while the manufacturer, if they cut themselves adrift from the academic side chemistry, are just as likely to conduct their own industry from a too narrowly practical point of view. Therefore such *rapprochement* as has been brought about, however incompletely, during the past year through the Section discussions seems to me to be of distinct value to both teachers and technologists, and is a branch of the Society work which should receive every encouragement. It appears remarkable, in fact, when the history of modern scientific and technical education in this country is impartially considered, that the voice of chemical industry should not have made itself more distinctly heard. It must be remembered that the modern revival in what is called technical education, which took practical shape more than a quarter of a century ago, had for its motive the scientific education of those who were about to engage in manufacturing or constructive industry. It was considered to be the crying want of the age, not on account of what was going on among foreign nations in this direction, but also because it was rightly thought that the old scientific training of the Universities was too academic and unpractical for turning out technologists of any use. The Technical Colleges, Schools, and Polytechnics which developed out of the movement were intended to supply this deficiency in our education, machinery, and in those directions in which these new institutions can claim to have fulfilled their mission with any degree of success it is mainly, if not entirely, due to the recognition of that principle which is recognised in America and on the Continent much more fully than here—I refer to the principle of co-operation between the teachers and the representatives of industry. Whether the newer institutions here have produced any distinct influence upon British chemical industry is a point which I have dealt with to some extent in my address to the Chemical Society two years ago. It is a question which primarily affects the chemical manufacturers, and it is but natural that we who are devoting our lives to this work should look to them for some definite pronouncement. Speaking as a representative of the teachers, I may say that this matter is one of supreme importance to us. We are doing our best, according to our high and according to the means at our disposal, to play in the hands of those with whom rests the future of chemical industry in this country. The experiment has been carried on in various centres for about a quarter of a century, but has any serious result followed from our efforts? Do our chemical industries show any marked development as the outcome of this modern departure in the way of technical education? If the experiment has been a failure, is it the fault of the system, of the teachers, or of the manufacturers? These are questions which are most appropriately raised before this Society and although I dare not flatter myself that any considerations that I can lay before you are likely to lead to an immediate and definite answer, I can at any rate claim with a footing in both camps, to attempt to clear the ground for a better understanding between the parties concerned.

More especially is this necessary now, because, as has been already pointed out, all the recent discussions have centred round the Universities, and the institution which I represent, the Technical Schools and Colleges, have been passed over. Whether this is to be taken as an intimation that we are discharging our functions perfectly as to be outside the zone of discussion, or whether we are doing our work so badly that we are to be eliminated as a negligible quantity, or whether, again, it is thought that the Universities can do something for chemical industry which the technical education movement has hitherto proved incompetent to deal with, are questions on which the voices of chemical manufacturers should surely be heard. Whether there is concordance or discordance at this stage is immaterial, for if the signs of the times are properly read, there can be no doubt that a crisis is approaching both for teachers and technologist and the sooner a definite understanding is evolved out of the conflict of views the better will it be for the welfare of the nation. It is only necessary to remind you that

* See "Nature," March 4th, 1909.

† "Journal of Industrial and Engineering Chemistry," Vol. I, No. 2, p. 102. The article formed the subject of a communication to the Baltimore meeting of the American Chemical Society in December of last year.

Among other influences, the new Patent Act, under which large factories are to be established by foreign manufacturers in this country, cannot but have a profound influence upon our existing factories, and indirectly upon the teaching institutions.

The Statement of the Case by Teachers and Manufacturers.

The isolated expression of individual opinions or the interchange of views between the manufacturers and teachers has hitherto resulted chiefly in emphasising points of disagreement. In view of the crying demand for a constructive policy with respect to the training of chemical technologists this result is to be deplored. I have unfortunately been unable to take part in any of the recent discussions, but from all the information which I have gathered during a very long period, and as the result of many years' consideration of the points at issue, I am fully persuaded that one of the main reasons why the two parties have not in the past been brought to more intimate association and why the discussions on our subject have been less prolific of practical results, whether educational or industrial, than in other departments of applied science, is because there has been a lack of discrimination on both sides. The contending parties have not made sufficient endeavour to enter into each other's point of view. In one sense the discussions have been too general to be of practical value and in another sense too narrow to affect the broad question of educational policy. As a result there has been much talk which is very wide of the mark, and only occasionally have we received contributions which could be said to reach the core of the subject. The problem is confessedly one of the most difficult that has been presented to educationists since technical education was begun; hence the greater need for discrimination and a clearer mutual understanding. I am fully persuaded that in many cases where the education of the technical or industrial chemist has been under discussion, the disputants have, quite unconsciously, been talking about totally different people, and am equally persuaded that if more precise notions had been formed at the outset, and that if the discussion of the question had set out from that common ground, which is really at the basis of the whole matter, many of the points of difference between the parties would disappear. Many of the most divergent and apparently conflicting views are not really incompatible: the want of agreement is apparent and not real—had the teachers and technologists defined more precisely what kind of "chemical chemist" they were talking about, had the teachers more fully realised what an enormous range of heterogeneous manufacture is covered by the term "chemical industry," and had the manufacturers more fully realised the unity of the fundamental sciences which underlie their operations, there would have been a much nearer concordance, and the cause which we all have at heart, the promotion of British chemical industry, would have made greater advance.

I venture to think that I know what both parties mean, although I take up this position with extreme diffidence, and only by virtue of the office which you have conferred upon me. If the air can be cleared so that we can get a better view of each other's requirements, no good to the cause may be effected. In the first place, then, with respect to that want of discrimination which allusion has been made, it may be useful to try to formulate some definite notions from which both parties can set out. The term "Chemical Industry," as understood by us, comprises the branches of manufacture coming under more than 20 distinct headings, the degree of heterogeneity unknown in any other branch of industry. The general principles of chemistry, physics, mechanics, and so forth are, no doubt, the same in every department, and up to this point the work of the teacher is fairly plain sailing. But when we go into details, the mode of applying these principles differs, and divergences take place in various directions and to a greater or lesser degree according to the nature of the industry. When, therefore, the training of an industrial chemist is under discussion the first question to be settled is what part of his training are we talking about? Is it the preparatory general scientific education, or is it this *plus* something

more that he will require by way of preparation for his career? Now whatever views may be held with respect to the connection between technical education and industrial chemistry in this country, it is generally conceded that there must be a sound preparatory scientific education. At any rate we have got as far as that after a quarter of a century of strenuous work—a small mouse perhaps as the result of much painful labour, but at any rate it is an advance upon the state of affairs that existed in the days of my studentship, when it was considered that a chemical manufacturer could get all the training he required by going straight into the factory from school or college, where, by the way, there was no science teaching at all, or, what was worse, a dreary, uninspiring, pedagogic teaching from books which passed for scientific training. If, therefore, we are now all agreed that there must be a scientific basis to build upon, the questions for discussion are, first, what is to be the nature of this preliminary training? and, secondly, where is that training to be given?

Having reached this stage the next point that arises is this:—Passing over all questions of general preliminary education, with which we are not now concerned, are we agreed that the student who is taking up chemistry for an industrial career needs anything more than a knowledge of the general principles of the science and of such allied sciences as are necessary for him to become a fairly proficient master of those principles? Is something more to be added to the mastery of principles, and if so, what is that "something more" to be? Here there is conflict of opinion due, I believe, to want of discrimination on both sides. Some teachers maintain that the chemical training of the student, if thorough, and if made to comprise original research as a part of this advanced training, is all-sufficient, and that these are the kind of men that our factories are in need of. On this last point I quite agree with the teachers: our factories do need such men, and the development of the research faculty should be made a fundamental part of the advanced training of every chemist who is to hold any position of responsibility in a factory. But there is something more which many of the teachers have left out of consideration. Supposing we turn out such efficiently equipped men—thorough chemists and full of originality; supposing, further, that they made valuable discoveries of new products or of new processes, would they be competent to realise these discoveries industrially? I, for one, doubt it: at any rate, I should regard it as extremely risky to invest capital in any discovery worked under such auspices. It is here that there has been want of discrimination. There is such a thing as factory experience. The purely academic teachers have, so to say, washed their hands of all responsibility in connection with this part of the student's training; they pass it over as requiring no consideration from the educational side. The assumption is made that no educational preparation for this, to us, most important part of the career of the industrial chemist is needed beyond the general training in scientific principles. It is true that the infinitely diversified details in construction of plant and methods of working in the 20 odd departments of chemical industry, quite apart from the pure chemistry of the processes—in other words, the pure *technique* of each particular industry, cannot be taught in any educational institution, excepting perhaps in certain special cases which may be considered subsequently. But the admission that extreme specialisation cannot be realised in practical educational policy by no means carries with it the consequence that no preparation for the factory experience is to be looked for from the modern technical education movement.

Here, I think, there has been some misapprehension as to the functions of technical education in our subject. If the manufacturers imagined that the new departure would enable their works to be staffed by expert technologists and if they were disappointed because no such prodigies were forthcoming, it is because they underestimated the complexity of the *technique* of their own industry. In fact, the more closely we look into the discussions the more evident does it appear that the conflict of opinion is mainly due to the two parties having

quite different classes of "technical chemists" in mind. Those teachers who are clamouring for the staffing of our factories by scientifically trained chemists have, if I may say so, damaged their case by leaving out of consideration the expert technologist—the man whose knowledge of *technique* enables him to translate a new discovery into terms of pounds, shillings, and pence—in the present state of competition one might go so far as to say into the fraction of a penny! This is the point on which we must arrive at an understanding if any practical policy is to be evolved out of our conferences. The education of this "chemical technologist" must surely be of precisely the same order of importance for chemical industry as the education of the "pure" chemist. The academic teachers are right as far as they go—as I have already said, we do want highly competent scientific chemists in the works, but they are as inseparable from the "technologist" or the "chemical engineer" or the "practical manufacturer" or whatever we like to call him as were the Siamese twins. A severance of the union means death to both. And if, therefore, the other half of the twin—the scientific chemist—is really essential for the life of the whole, as many teachers believe, then those manufacturers who talk as though this component might be left out of consideration are doing equal damage to their own cause. On carefully considering the various expressions of opinion it will, I think, be found that the teachers have had more or less in mind the research chemist and the manufacturer the chemical engineer in the broad sense of the term. Perhaps it may not be possible—at least in this country—to draw a hard and fast line between the two classes; or, it may be asked whether it is not possible to combine the faculties of both in the same individual. This is conceivable, but it is an ideal applicable to but few and one which would be extremely difficult if not impossible to realise from the educational point of view. We must look the situation fairly in the face. The research chemist ought to be producible from the Universities and Technical Colleges. If we do not turn him out from the latter, so much the worse for that class of institution which I represent, and on this point I shall have something further to say in extension of the views which were stated in my address to the Chemical Society two years ago. With respect to the chemical technologist the question is whether he can be produced under any of our existing educational curricula, or whether the factory is the only proper training ground. This is a point which requires further consideration and is indeed the very subject on which above all others the manufacturers and the teachers should come to an understanding, if for no other reason because of the enormous practical difficulties which surround it from the educational side, owing to that extreme heterogeneity which is not and cannot be realised by any teacher of pure science who has not had practical experience as a manufacturer. The discussions by the Birmingham and Liverpool Sections last autumn are particularly valuable from this point of view as they practically centre round this aspect of the technical education question.

The Requirements of Chemical Industry.

It is impossible to hold any profitable discussion as to the nature of the training or the place of training unless we discriminate between the two classes of students referred to. I believe that in the Midland Counties, the distinction is emphasized by speaking of the man who is carrying on research work in connection with an industry as the "technical chemist" and the man who is conducting the factory operations as the "chemical technologist." But this is simply a question of terminology, and as long as we know what kind of student we are talking about there need be no confusion. The research chemist may be disposed of at this stage by defining him as a man who has received the highest possible training as a scientific chemist and whose originality and resourcefulness have been developed by prolonged systematic research. It is therefore quite immaterial whether he receives his training in a University or in a Technical College, provided that the staff and equipment are efficient, although, of course, by virtue of their functions, the Universities

in this country have the advantage over the Technical Colleges taken as a whole.

But when we come to the consideration of the chemical technologist, there must be much more discrimination between the requirements of the different branches of chemical industry by both teachers and manufacturers before the conflicting views can be brought into harmony. For this reason I think that the recent attempts to introduce some order into the chaos by Prof. Donnan and Mr. Heathcote, in the papers which led to the discussion in the Liverpool and Birmingham Sections last year, are welcome contributions to the subject, although, as you are aware, the University aspect of the question has been mainly dealt with. It appears from these discussions, and from the replies to the queries circulated by the Birmingham Section, that many of the contributors had in mind either the research chemist pure and simple or the technologist pure and simple, and others seem to imply that both faculties can be combined in the same individual. As I have just said, this combination is practically unrealisable from the teachers' point of view, and if insisted upon in the factory, can only result in crippling the efficiency of both the chemist and the technologist.

The requirements of a chemical factory are capable of being broadly classified under certain distinct headings.

(1) Research for the discovery of new products or new processes for producing known substances, or for the improvement of processes already being carried on.

(2) Supervision of the factory operations with respect both to plant and products, and requiring as an accessory the valuation of the raw materials and finished product as well as in many processes the testing of the intermediate products.

(3) A knowledge of the state of the markets with respect to the supply and cost of raw materials and the demand for the finished products, and the most advantageous means of introducing the latter to the consumers.

It is not pretended that this classification is exhaustive, but I think it covers the ground sufficiently for the present purpose of further discrimination.

Development depends upon a combination of all three. If No. 1 is ignored then Nos. 2 and 3 may serve to keep certain staple industries going for a longer or shorter period at the risk of extermination by No. 1. Many of the older industries in this country have for a long time been maintained under Nos. 2 and 3. It may be prudent to raise the question incidentally whether this state of affairs is likely to continue indefinitely. The answer to this is bound up with an intimate knowledge of the actual state of particular industries which I do not pretend to possess, but in so far as it is connected with the research question, something more will be said later.

No. 1 is primarily the function of the research chemist, backed up by Nos. 2 and 3. Whether this kind of work shall be done in the factory itself or elsewhere is a subordinate point, which may be discussed subsequently, but I wish to associate myself with those teachers who insist that this work is an essential requirement of every branch of chemical industry.

No. 2 is a heterogeneous requirement and is met by various people between whose functions, even if they overlap, it is necessary to discriminate. There are directors or managers in charge of the whole factory, there are foremen in charge of particular operations, there are mechanical or engineers responsible for plant and machinery, and there are labourers whose duties it is to carry out the various operations. The valuation of materials is the work of the analyst, and may or may not be done in the factory. The "works chemist," as understood in this country, must be considered as coming in one way or another under this category. Requirement No. 1 is not frequently complied with in the exclusive sense; if recognised generally overlaps No. 2.

No. 3 is the work of the office—the commercial intelligence department, or, I should prefer to say, the intelligent commercial department, and may be carried out by people having none of the qualifications of Nos. 1 and 2. I dare not attempt to deal with this requirement from the educational point of view, for I am fully aware of my own ignorance.

I feel that it is almost necessary to apologise for bringing these very elementary considerations before this Society, but I claim forbearance because I am taking advantage of the opportunity for addressing also the teachers, at the nature of the educational problem with which we have to deal must be fully realised. Also I would call attention to an omission which has no doubt been supplied by many present, and that is the status of the proprietor or director of a chemical factory. This also is an educational question, because it is evident that the success of any factory is largely dependent upon the policy directed from above, and that policy should be based on a full knowledge of the requirements Nos. 1, 2, and 3. Of course I do not necessarily mean an expert knowledge but a general knowledge, and the deeper it goes and the more completely the proprietor or director is in touch with the various requirements specified, the better will it be for the success of the concern. It is certain that the manufacturers of my own and preceding generations had no such facilities for obtaining a scientific training in this country as are now available for the future generation. No less certain is it that chemical science, and with it chemical industry, is developing rapidly, and the manufacturer of the future will have to be far more thoroughly imbued with the scientific spirit than his predecessors. The problem of the education of the industrial chemist must, in fact, be made to embrace the education of the proprietor, for, upon his training, *i.e.*, his "attitude of mind," will depend the future of his industry.

And now if we come back to the technical education movement which had for its object the improvement of our manufacturing industries, it will be found that our subject the current has been flowing mainly in the direction of the second of the foregoing requirements. There are a few notable exceptions to be found in certain institutions here and there which it would be invidious to name, and which, for the present, may be left out of consideration. The discussions about education in applied chemistry have, from the manufacturer's side, tacitly, if not explicitly, taken it for granted that the teacher is to supply chemical technologists. If the manufacturers have left out the research chemist they are to blame; if the teachers have harped so strongly upon the research chemist as to pour contempt upon the much despised hybrid chemist and engineer, they are equally to blame. Whether our chemical industries are progressing or stagnating or declining, you know much better than I; but whatever may be the actual state of affairs, to suppose that by research alone without technological co-operation we shall be saved is simply preposterous. As already stated, the education of the "works chemist," is no less pressing from the industrial point of view, than is the training of the research chemist. Indeed it is more pressing, because, given a student with the necessary faculties, we can develop those faculties in our educational institutions. Whether manufacturers will make profitable use of him when we have turned him out depends upon themselves, but with respect to the particular product which we of the Technical Schools are supposed to furnish, there is such conflict of opinion and divergence of requirements that I feel it necessary to repeat once again that we are here confronted with one of the most difficult problems in the whole range of technical education.

The "works chemist" as defined, and excluding the pure mechanic or engineer, must be qualified, according to the post which he is called upon to fill, to come under category No. 2, with (possibly) an incursion into the domain of No. 1. He would presumably be placed in a subordinate position at first and, let us hope, have a prospect of promotion. The analytical side of his training offers no particular difficulty and need not be further considered. The extent to which the factory workman shall be brought within the range of technical education is an open question. This, although a digression from the main theme, is a point on which the manufacturers would do well to let us have a definite expression of opinion. As far as my experience goes, and I believe that the majority share this view, such rudimentary smattering of chemical science as he could get by attending evening classes would be of no real use, and if his education is

to be considered by the Technical Schools at all it is certainly not from the chemical side. This matter may not appear of pressing importance to the manufacturers, but to the teachers it is really one of considerable importance because it involves a question of principle which for many years I have been endeavouring to make clear. The "platform cry," if I may say so, of the modern technical education movement was the education of the workman or artisan. At first we heard very little about any other class of person. This was due to that cause which I have already specified—the prepotency of the engineering influence. Not the least disparagement is intended by this assertion, because, from the engineering point of view (using the term in the broad sense of constructive mechanical industry), those who promoted the new education were of opinion that the skill of the workman would be improved by educating him in the scientific principles underlying his occupation. That seems a sound principle; how far it has been successful in practice is a question for experts, but so far as we are concerned I have pointed out again and again that the workman in a chemical factory is not the analogue of the skilled artisan of the engineering workshops, and that the handicraft view of the technical education is worthless from the point of view of the chemical manufacturer. Moreover, the chemical workman himself, as far as I know him, is a very intelligent type, and he knows that the success of his occupation, provided he discharges his duties faithfully, rests entirely in the hands of the higher powers. If the manufacturers agree on this point, it would be of immense value to the cause of technical education in this country if they would unhesitatingly proclaim their views.

The difficulty of meeting the requirements comprised under the second heading is due to a combination of circumstances which call for consideration by both teachers and manufacturers. By the "works chemist" (excluding the analyst, the mechanic, and the workman), I mean a chemist with more or less knowledge of the general principles of engineering as applied to chemical factory plant. He cannot be too much of a chemist, and the more he is of an engineer the more competent will he be to discharge his duties. Now the first difficulty that confronts the educational authorities is, where is this combination of qualifications to be acquired? That resolves itself again into a question of ways and means. But before attempting to deal with this part of the subject let us endeavour to come to some understanding concerning the engineering requirements. It must be realised by the teachers—and this cannot be too strongly insisted upon—that no fixed standard of engineering qualifications for chemical industry as a whole can possibly be set up. It is a sliding scale. There are some industries in which a small number of chemical reactions and a few products are concerned and in which the whole success turns upon the perfection of the plant. There are other industries in which large numbers of very diverse chemical reactions are carried out, each requiring its own special plant. In one class the engineering requirements predominate and in the other the chemical requirements. Between these extremes there is every possible gradation. When, therefore, chemical industry calls for "technically" educated chemists, one manufacturer may have in mind a man who is primarily an engineer and another manufacturer a man who is primarily a chemist. If technical education can do anything for chemical industry—as we believe it can—it must be realised that this is the state of affairs which the educational establishments have to meet, and it must also be borne in mind that there are factories of every degree of organisation, from the large works where the division of function between chemist and engineer is sharply defined, down to the smaller and much more numerous works where there is no division of function. In view of this state of affairs—in view of the circumstance that every manufacturer who expresses an opinion is reading into the requirements of the "works chemist" the requirements of his own industry, and in view also of the fact that the engineering side of the education has hitherto been more or less neglected in this country, it is not to be wondered at if our educational machinery has so far been found incapable of dealing

with all the conditions presented to it. That is why it is so desirable for the manufacturers and educationists to co-operate in developing a constructive policy for the guidance of the teachers and for the equipment of our factories with the most efficiently trained men. It is satisfactory to note, by the way, in this connection, that several of our leading members took part in framing the scheme for the Technological Examination of the Institute of Chemistry.

The Nature and Scope of the Preliminary Training.

The kind of education most suitable for the student who is preparing for a career in industrial chemistry may be considered at first from the point of view of the Technical School or College, because that is the class of institution which, theoretically at any rate, was established with the avowed object of doing this work. If any of them have since their foundation undergone a change of function so as to become cramming establishments, that is a deplorable degeneration from which the manufacturers ought to have helped to save them. In order that the situation may be fairly grasped by both teachers and manufacturers, I will invite attention to the historical development of the technical education movement, and, for the sake of brevity, it will be sufficient to speak at this stage of Technical Schools in the abstract without reference to rank and without attempting to discriminate between Colleges and Polytechnics. So far as my memory extends, the movement was by no means welcomed at first by the various industries concerned. In some cases it was openly opposed, the hostility coming chiefly from those industries where the apprenticeship system prevailed, and where the possibility of receiving training outside the existing establishments threatened to do away with the emoluments derived from premiums. Added to this there was the genuine belief that the college-trained youth was a helpless being in workshop or factory, a survival from the period of the purely academic teaching of science in the Universities. It happened also that the movement was set going at a time when electricity as a branch of applied science was advancing with rapid strides, and the demand for "technical" electricians filled the classes in this subject. But although the engineering industries were the first whose "vested interests" were attacked, we must do them the justice to admit that the former opposition from this quarter, if not wholly extinct, has at any rate almost entirely subsided, and it is the engineers (including electrical engineers) who have been the first to set their house in order or, in other words, to take an enlightened view of the function of the Technical Schools with respect to their industry. The chemical manufacturers at first took little or no interest in the movement; I believe the majority held the same view as the engineers—that the college-trained student was not only a useless, but even a dangerous person to let loose in a chemical factory. I am not sure whether this belief is even now extinct. When therefore the new departure in educational methods began to obtrude itself upon the notice of the chemical manufacturers, who were largely stimulated by the general and technical press and by certain teachers at home, as well as by the example set by other countries abroad, the first point that the technical schools had to meet was the demand for what were called *practical* as distinguished from theoretical men. It used to be the custom in my younger days to speak of theory and practice as two opposing forces or antitheses—it was thought that success alone rested with the practical man and that the merely theoretical man meant disaster. The development of both chemical science and of chemical industry since that period has done much to break down this antagonism, but, if theory and practice are not yet completely welded in the mind of our manufacturers, we have arrived at this common understanding, that the training of the "works chemist" must begin with a thorough grounding in the general principles of chemistry and allied sciences.

The Technical Institutions in carrying out this part of their work have as the raw material of their branch of manufacture the lad who is supposed to have completed his ordinary school education. I am not now considering

evening classes because this phase of technical education, as I have frequently pointed out, cannot seriously influence the development of chemical industry excepting under certain very special conditions which may be referred to later; the student who is entering for a complete systematic course extending over at least three years is the future chemical technologist with whom we have to deal. In spite of an entrance examination which is imposed by the higher Technical Colleges, our raw material is by no means of uniform quality. Both individual differences and the ordinary school training have to be reckoned with. The latter factor opens up another aspect of the education question which is beyond the scope of this address, although the scientific attainments of the students who enter our colleges with the object of becoming industrial chemists must evidently be a matter of concern to the teachers. It may be of use therefore if I state at once that the general experience of our staffs has led to the conclusion that on the whole we much prefer that the students entering our College Chemical Departments should have had no previous school training in science. Such training is generally too shallow to be of use; it has only the effect of stiffening the mental attitude to the point of conceit and of making these students less teachable than those who have not been through the school science classes. I am afraid this is tantamount to a declaration that science teaching in the schools is defective. From our point of view it certainly is, and in calling attention to this opinion, so generally held by the teaching staffs of the Technical Schools and Colleges, it may be well to point out that it is not the principle but the method which we are attacking. There is no reason why school science should not be taught in such a way as to make it of real preparatory value. This question of juvenile science teaching is of course a very well worn topic, but I am glad of the present opportunity of acknowledging that any improvement which may have been effected in this direction of late years is largely due to the persistent campaign carried on by my colleague Prof. H. E. Armstrong who, more than any other educational authority, has helped to inculcate the sound doctrine that science teaching consists on the training of *faculty* and not in cramming the memory with disjointed scraps of information.

But in spite of the efforts of the reformers of school education the science teaching, judging from the results offered to the Technical Schools, show that there is still ample scope for improvement, and the present opportunity is a favourable one for bringing this state of affairs under the notice of the manufacturers. If we wish to see our factories staffed by "home made" chemists it is obvious that the higher the plane on which the Technical College can begin its work the more efficient will be the finished product. The teachers in these colleges are unquestionably in a better position than any other class of teacher to realise the defects of school science teaching; it is they who are confronted with the products of this teaching year after year, and it is they who are called upon to fill in the gap between the school period and the entry into industry with a training during which the student must be imbued with the scientific spirit as a living force. It is the *reality* of science when taught with a view to its applications in industry that has enabled this class of teacher to do good service to the cause of elementary science teaching. It is not going too far to say that the amelioration in science teaching in every grade—from the elementary school to the University—during the last quarter century is mainly attributable to the reaction of "applied" science teaching upon "pure" science teaching. The stimulus to reform has come from those who, by virtue of their knowledge of the practical requirements of the technologist, have had brought home to them in full force the shortcomings of the old mnemonical and didactic method which had been so long prevalent in this country. If, for our industry, the requirements of chemical technology call for still further reform in the elementary teaching of science during the schoolboy period, the manufacturers would do good service to the cause of education if they would make their voices heard also in this direction.

The practical outcome of the existing state of affairs

s that at the Technical College we have to begin from the beginning. In dealing with the nature of the training therefore we have to consider the subjects which are necessary and the time over which the training should extend. On this last point there is some divergence of opinion. When I first entered the Finsbury Technical College in 1885, two years were considered sufficient. It was soon found that this was inadequate, and the course was extended to three years. I certainly think that this period should be taken as a minimum. With respect to subjects it is perhaps only necessary to refer to the published programmes where the courses laid down by the various Technical Schools are set forth in detail. But in connection with certain questions of principle underlying the curricula of the Technical Schools it seems desirable to make use of this opportunity for again bringing the teachers and manufacturers into the arena of discussion.

In the first place it is absolutely necessary to come to a understanding as to what can and what cannot be done during this three years' training; in other words, the function of the Technical College in relation to our industry requires defining with a degree of precision that is indispensable if the teachers and manufacturers are to be mutually helpful. The case may be stated in these terms:—A youth fresh from school with, let us say, no preparatory scientific training, has in the course of three years to receive that thorough grounding in the principles of chemistry and those allied sciences which are necessary to qualify him for becoming a "works chemist" as defined. If we consider critically what this means in the light of the known requirements of chemical industry must be conceded that this is what would be called a large order." The question is how far can the teachers execute it? Of course there are Technical Schools of various grades, but from our point of view it is *only* those which have organised curricula for day students which need be considered here. Now the subjects which, in addition to chemistry, are generally considered indispensable for the future chemical technologist are mathematics, physics (including electricity), and mechanics, including drawing-office practice. It is essential to emphasise the point that at this stage we are concerned only with the fundamental principles of these sciences; a practical application to particular industries cannot in our subject be attempted. We hold, and I think solely, that any attempt at specialisation before the soundwork of scientific principles has been laid is absolutely wrong both from the educational and the industrial point of view. Now it takes at least two years with the average student to lay what may be called an elementary foundation in these subjects, and so there is left but one year for more advanced instruction. How far then does the course enable us to turn out a youth who can be described as more than a potential chemical technologist? Chemical manufacturers have a perfect right to challenge the application of the prefix "technical" as descriptive of institutions. The course which I have outlined cannot meet the conditions specified be honestly regarded as more than a preliminary training. It does not and it must not pretend to add to the scientific training that something more" which is necessary for the technologist. There is no time for specialisation and there are not very few Technical Schools in this country (exclusive of Universities) where specialisation is possible. The case is in reality even worse than this; the handicraft theory of technical education was for so long predominant that there were at first only a very few Technical Schools working up to the level of systematic and organised curricula, although, I am glad to say, of late years there has been some advance in this direction. But if any general and substantial development in the qualifications of our "works chemists" is to be brought about, the manufacturers and the parents of our students will have to realise that we must have sufficient time for our work. The half-trained youth is not a fair criterion of the possibilities of technical education. It is unjust to the schools and colleges; it is a most shortsighted policy, and it is seriously damaging the cause of chemical industry when such men are taken into the factories. I speak strongly on this point it is because I feel strongly.

This "scamping" of the education of our future technologists is one among the many difficulties which hamper the work of the Technical Schools and which provokes the hostility of educationists, who naturally read into this reluctance to give sufficient training the national attitude towards scientific education in general, and towards industrial development in particular.

It might be inferred from this declaration of policy that I have altogether given away the case for the technical education of the "works chemist"—that there is nothing more being done in our Technical Schools and Colleges than such ordinary general scientific training as might have been given anywhere else; that such institutions are not "technical" in the manufacturer's sense at all, and that there was no need for bringing this new educational machinery into existence. It is needless to say that from the teacher's point of view such an inference would be quite erroneous. In the first place it may be pointed out that before the technical education movement was initiated there were only a very few institutions in this country where an adequate training could be given. Indeed there was no attempt in any institution, excepting perhaps the Royal School of Mines, to organise the curriculum with special reference to the application of science to industry. The Universities at that time looked askance at "applied" science. We had to pick up our education as best we could; a course of chemistry here, a course of lectures on physics there, and a course on mechanics by purely lecture-room method somewhere else. Strangely enough mathematics was not taught as an integral part of the system, but had to be acquired as an "extra," and the same was true for modern languages. It was to co-ordinate the science teaching and to give opportunity for training in all the necessary subjects in the same institution that the modern Technical Schools were called into existence. Where these institutions are discharging their functions adequately we claim therefore that a kind of training has been made possible that was impossible before the initiation of the movement. Had such opportunities for the would-be chemical technologist existed in my younger days we should have heard less about the antagonism between "theory" and "practice," and I think it more than probable that I should have been addressing you from this chair as a manufacturer rather than as a teacher.

Not only has the technical education movement given us a new class of science school, but as I have already said, the reaction upon the teaching of science both pure and applied has been most beneficial. How far particular Technical Schools are really capable of doing for chemical industry that which they are supposed to be doing for other industries is a matter for further consideration, but on behalf of those which are doing their work efficiently it may be fairly claimed that their finished products are far better equipped for becoming technologists than was formerly possible. To this extent the movement can and should be regarded as a valuable addition to our national educational resources. Whether the manufacturers will admit that the training is in any way "technical" is partly a matter of definition and partly dependent upon the kind of teaching. I have admitted that our courses are preliminary and I agree with the manufacturers that a chemical technologist is a chemist plus a great deal more, and the next points that arise are therefore (1) whether the technical education can be developed into technological training, and, if so, where? (2) Whether the teaching in the Technical Schools can in any way be made to approach the diversified requirements of the different branches of chemical industry so as to make the preparation for technology more effective. In other words, can the teachers go further under the present system in delivering over to the manufacturers men of a higher degree of preparedness than was ever before attempted? These two questions require separate handling, and the latter, with which I propose to deal next, involves the consideration of the curriculum in somewhat greater detail.

The Nature of the Science Teaching in Technical Schools.

In dealing with this subject I am fully aware that I am entering into a controversial atmosphere and I can

do no more than give expression to personal opinion based on experience of both sides of the question. The practical difficulties which are encountered in carrying out any scheme of instruction which could be regarded as ideal from the manufacturer's point of view—and that, be it remembered, is nominally our function—i.e. both internal and external. From the outside we have manufacturers and parents interposing difficulties or laying down conditions which, if complied with, would strike at the very root of the principle of modern technical education. I think the "blessed word" *technical* is responsible for some of these external difficulties. A parent enters his son at one of our colleges because it is "technical," and in his mind that term conveys an impression that the teaching is practical as distinguished from theoretical. The traditional parent who told the Professor of Chemistry that he did not want his son "to learn about atoms and molecules and benzene rings and all that rubbish," but that "he wanted him to be taught how to make soap," is not, or at any rate was not, a mythical person, because this educational feat was actually expected from me soon after taking up my duties at Finsbury. Fortunately I was enabled to meet the parent on his own ground by sheltering myself behind the excuse that our college had not yet developed a soap-making wing, and that we were therefore not in a position to admit his son. It is to be hoped that this type of manufacturer is extinct; but I relate the experience again because it is thoroughly illustrative of the spirit in which the technical education movement was at first received by many manufacturers, and it is that spirit which had to be allayed—I may add with much expenditure of energy on the part of the teachers—before the true function of technical education with respect to chemical industry could be rightly appreciated.

Coming in the first place to the teaching of chemistry, let it be at once understood that so long as we are concerned with fundamental principles there is only one chemistry whatever future the student may have in view. And let it be further understood that the sound teaching of the general principles of our science involves just as much theory as practice. Mr. Heathcote and Prof. Donnan's remarks on this subject in their papers leading to the discussions at Birmingham and Liverpool are very much to the point. This situation must be grasped, and the sooner the better. Any manufacturer who imagines that practical chemistry is the peculiar possession of the Technical College and that theoretical chemistry is only of use for degree-winning purposes is labouring under a serious misapprehension. The scientific groundwork which by agreement is to be laid during the preliminary training is essentially a theoretical groundwork—it is the abstract summary of our existing knowledge of facts with attempted explanations of the grouped facts by general hypotheses which in turn prompt the discovery of new facts. That is the method by which our science, in common with all other sciences, has been built up. The most practical of our manufacturers must admit that the doctrines which are inculcated in the laboratory or lecture room are the outcome of scientific theorising. To teach or to let the student learn for himself the facts only is to put back the hands of the clock. Such training, however "technical" it might be considered, is of no real value as an educational discipline; it would be of less use in fitting the student for a career in industrial chemistry than would be a prolonged drilling in the dead languages. To divorce theory from facts is to kill the training of the imaginative faculty; the result of devalued teaching of this kind is the production of pedagogues of the narrowest type for teachers and of mere labourers instead of chemical technologists. Just as imagination, fed by facts and stimulated by theory, has developed and is developing pure science, so will it develop applied science, dependent as is the latter upon scientific discovery for its advancement. I have felt it necessary to put forward this plea for what many are pleased to designate "mere theory," not only because of the possible existence of manufacturers of the type exemplified by the parent referred to above, but also because I am persuaded that even now there are many manufacturers in this country who do not realise how largely their

industry is the product of scientific theorising. Had their operations and processes been made to depend upon facts only irrespective of any connecting theoretic principle it may safely be asserted that chemical industry would still remain in that state of empiricism which the whole tendency of modern development is to eliminate. In a remarkable address delivered by Prof. Lyon (afterwards Lord Playfair) 58 years ago under the title, "The Study of Abstract Science essential to the Progress of Industry," being the introductory lecture to the course of chemistry at the Royal School of Mines for the Session 1851–1852, occurs a passage which bears so closely upon this subject that I will quote it in full:—

"Intellect is on the stretch to get forward, and the nation which holds not by it will soon be left behind. For a long time, practice, standing still in the pride of empiricism, and in the ungrateful forgetfulness of what science has done in its development, reared upon it the old and vulgar adage 'an ounce of practice is worth a ton of theory.' This wretched inscription acted like a Gorgon's head, and turned to stone the aspirations of science. Believe it not! for a grain of theory, if that be an expression for science, will when planted like the mustard-seed of Scripture, grow and wax into the greatest of trees."

If therefore the teaching of chemistry in the Technical Schools is to be of the ordinary kind there still remain the question, as yet only partially met, whether there was any necessity from the manufacturer's point of view for creating this new class of institution. The answer has to some extent been given in calling attention to the co-ordinated courses of instruction made possible in these schools. I should now like to add that the demand for a training in chemistry with a view to its subsequent application to industry has enabled us to improve on chemical teaching so that our finished products are distinctly better chemists as chemists than were ever turned out in the same time under the old system of making gas and "test-tubing" for acids and bases. This improvement we claim unhesitatingly as one of the results of the modern technical education movement.

The "technicalising" of Chemical Teaching.

If then as manufacturers we now acknowledge that the teaching of theory is as indispensable as the training in experimental facts, I am prepared to make a concession to chemical technology which for various reasons will probably be rejected by the teachers, or at any rate, by a majority of them. It is really the answer to the question previously raised—whether the teaching in the Technical Schools can be made to approximate more towards the requirements of chemical industry than was formerly possible. Speaking at present with respect only to chemistry I believe it can. Were I unable to justify this belief, I am bound to confess that these newer institutions could claim to be discharging no function differing in any way from those discharged by educational establishments of all ranks in which chemistry is taught for purely academic purposes. The students we are dealing with have presumably taken up the subject with a view to its industrial applications. There is a goal—necessarily ill-defined at first—towards which their studies are directed. I am not considering students who are in training for becoming teachers nor those who have in view a career as analyst. It is open to question, whether the Technical College is the proper place for these two classes of students. It may be taken into consideration also that the average student has no definite view with respect to any particular branch of chemical industry; his object is to become qualified for any opening that may occur. Only rarely, at any rate in London, do we get the sons of manufacturers who are going into their fathers' works. The conditions are undoubtedly different in those districts in which there are Technical Schools in the great centres of chemical industry. But this want of definite outlook is no real disadvantage in fact, from the educational point of view it is a distinct advantage because it compels the chemical teaching to take that general form which at this preliminary stage of training is alone permissible. It is agreed that specialisation should follow and be based upon the general training. It is this specialised training which strictly speaking is the

real "technical" education from the manufacturer's point of view.

But if we cannot get to the "technical" stage as thus defined under the conditions which we have to cope with in the existing Technical Schools, the chemical teaching can be given a bias in that direction without in any way detracting from its value as an educational discipline and without the least damage to its theoretical treatment. Consider the main purpose for which the chemistry is taught. Chemical manufacture in general terms consists in converting certain raw materials into useful products with maximum yield and minimum expenditure in the cost of production. If the teachers will bear this definition in mind it will I think be admitted, at least in principle, that it is possible to give a "technical" bias to the teaching both in the lecture-room and laboratory. When the general elementary course has been passed through and a fair grasp of fundamental principles has been acquired, the systematic treatment of elements and compounds, say in the second and third year courses, can surely be developed in much greater detail in cases where technical products are concerned. There is just as much pure scientific doctrine to be deduced from the study of useful products as from the study of useless products. The utilitarian view which the old-time academic teacher considered as derogatory should loom largely in the teaching of the Technical Schools. It is not contended that special detailed courses on particular industries should be attempted at any stage of the preparatory training. There is no time to teach technology in the strict sense, but there is time to prepare for technology, and the better the student is prepared the shorter will be his period of probation when he passes on to the higher stages of technological training in college or factory. If this spirit does not pervade the teaching I see no reason for our existence as Technical Schools.

All chemical manufacturing operations may be regarded as special illustrations of general principles, and by the skilful teacher may be made use of as such in dealing with advanced students. It will help the teaching considerably if it is brought home that a manufacturing operation is essentially a scientific operation—at least quite as scientific on a scale of hundredweights and tons as on a scale of a few grams. Moreover, the chemical reaction concerned in a manufacturing operation is associated with an element that was absolutely ignored in the old teaching of chemistry: I refer to the *economic* side of the reaction. Consider the training in our own days of studentship. We mixed our reagents indiscriminately and we made our preparations with a lavish expenditure of materials that would spell ruin if magnified to a manufacturing scale. What matter if we failed?; the sink was at hand, and the storekeeper round the corner with fresh supplies. From the point of view of the future technologist such teaching cannot but result in complete infitness for factory work. It is the duty of the Technical Schools to introduce this economic element into the teaching of chemistry, and that is why I am pleading for the "technicalising" of the curriculum. If this side of chemical teaching has hitherto been neglected it can only be because it has no examination value.

My views on this subject will be regarded as very heterodox from the purely academic standpoint. I have but little hope that they will be generally accepted at present, but if they coincide either partially or wholly with the views of chemical manufacturers it is from this Society that the educational world must receive authority for their adoption. As it is of great importance that there should be no confusion of ideas on this subject it may be advisable to reassert that by giving a technical bias to the teaching it is not proposed that technical chemistry in the sense of chemical technology, which is a specialised subject, should be made a part of that preliminary training which up to this stage I have alone had under consideration. It is necessary to arrive at a clear understanding on this point, because it will be remembered that in 1896-97 a special committee of the London County Council Technical Education Board was appointed under the chairmanship of Dr. W. J. Russell to consider the question of the teaching of chemistry, and some manufacturers laid it down in their evidence that

technological chemistry could not be taught in the Technical Schools at all.* That opinion had, I believe, much to do with the stereotyping of the academic traditions of chemical teaching, because the majority of teachers failed to realise that the manufacturers who expressed these views had really in mind the *technique* of particular industries. On this point I shall endeavour to show later that there has been want of discrimination and that the views expressed by the representatives of these industries have been unwarrantably spread over the whole field of chemical industry. But with respect to the present plea it is clear that these views do not tell against that technical bias which can be given to the teaching at a certain stage, which stage must obviously depend upon the status of the school or college.

Any opposition that may be offered to these suggestions will no doubt be based upon the practical difficulties connected with the carrying out of such technicalised teaching. That there are practical difficulties I do not deny; with respect to the teaching institutions the difficulties are both internal and external and it may be useful to point to some of them. In the first place there is the teaching staff. The ideal teacher for the Technical School is the man who can add to his teaching qualifications factory experience in some branch of chemical industry; unfortunately for the schools such men are rare. The man who has factory experience only is generally a very bad teacher, and, on the other hand, the teacher who has had no technological experience is too bookish. Then there is the difficulty of not being able to describe or illustrate the actual manufacturing processes. The average teacher has no time for keeping himself acquainted with the latest development of chemical industry, and if he attempts to deal with the technological side of such subjects as have a technological side he generally retails text-book information. I am sure the manufacturers will support me when I state that the majority of existing text-books, however admirable as scientific treatises, are generally erroneous, misleading, and antiquated in their treatment of manufacturing processes. The later developments both in the purely chemical theory and in the actual *technique* of manufacturing operations are the common possession of experts in the various branches of our industry years before they find their way into the text-books and through these into the Technical Schools. It is, I am afraid, unavoidable under our present system that the teaching staff should consist as a rule of men who have approached the subject from the academic rather than from the technological side, and who do not therefore possess any expert knowledge of chemical industry either in its general or special aspects. The tone of the teaching naturally reflects the training of the teacher, and that is why technicalised teaching is not likely to find much favour under existing conditions. Another difficulty of an external character arises from the circumstance that the manufacturers are not as a rule willing to allow students or teachers to see over their works, and thus the most important of all practical demonstrations—the actual manufacturing processes in operation—are not generally available for educational purposes. In the London district a few industries are liberal in this respect, notably gas and tar works, and breweries. I do not know how far the provincial schools have facilities given for visits to works, but speaking generally and on patriotic grounds I should like to take this opportunity of pointing out to the chemical manufacturers that they can further the cause of technical education considerably by allowing such students to visit their works. Of course, as Mr. Bailey has recently pointed out in his address to the Association of Technical Institutions, there are certain industries in which this is inadmissible, but my plea is not intended for such cases.

With respect to laboratory teaching in the Technical Schools there is also scope for "technicalisation." An

* The Report of this Committee was published in the London Technical Education Gazette for January, 1897, Vol. III., pp. 7-27. Another special Sub-Committee, under the chairmanship of Mr. H. J. Powell, was appointed subsequently to report upon the general question of the relation of Science to Industry. Their Report was published in a separate form by the London County Council Technical Education Board in 1902.

elementary drilling in experimental methods for the development of manipulative skill and the co-ordination of the reasoning faculty with the results of observation must of course be gone through. In so far as this stage of the work is general it calls for no special modification to suit the requirements of any particular class of student. It may be pointed out however that the elementary laboratory work of the modern chemical student has been raised to a very much higher scientific level than that which was considered sufficient in our younger days. The "practical" chemical training of the former generation is no doubt still fresh in the memory of many of us; the preparation of a few gases, the qualitative analysis all beautifully tabularised so as to prevent our learning any chemistry from our work, the quantitative analysis of a few stock salts, and, if we were advanced enough, a little organic and gas analysis. It was essentially a drilling in chemical analysis, and I am afraid that very imperfectly trained chemists were turned out under this régime, especially from the technological point of view. I do not undervalue analysis as a part of chemical training; on the contrary for the technical student I think it most important, and a certain amount of time may be allotted to it in the curriculum with advantage. But that differs from making analysis the whole practical training. Also it may be pointed out that even analysis is not a purely mechanical series of operations, but that there are scientific principles underlying these operations and it is for the teacher to see that the analytical work is not allowed to degenerate into mere chemical handicraft. With advanced students there is no reason why technical products should not be given for identification and analysis; it adds much to their interest in the work. But it is unnecessary here to dwell at too great a length upon the general practical training, although I should like to add that if the level has been raised and if our teaching has become more philosophical we are mainly indebted to a former occupant of this chair, Prof. Emerson Reynolds, who is unquestionably the pioneer reformer in the laboratory teaching of chemistry. I am glad of this opportunity of acknowledging the indebtedness of teachers to Prof. Reynolds because, amidst the later clamour, his share in the development of chemical teaching has been overlooked. The admirable series of little manuals on Experimental Chemistry which commenced with his Dublin introductory lectures in 1874 marked a new era in the methods of laboratory teaching; and, although developments in detail have since taken place, the fundamental principles which he laid down have undergone no modification; they are still the basis of all the most approved schemes of laboratory work.

In other directions also the laboratory teaching may be "technicalised," and to an increasing extent as the student becomes more advanced. A very excellent feature of modern laboratory work is the preparation of various inorganic and organic compounds from raw materials supplied to the student. This kind of work, if combined with the theoretical treatment in the lecture room, is of special value as introductory to the real technology, and it admits of the introduction of that very element which has hitherto been so much neglected; I refer again to the *economic* element. The technical bias can be made manifest. An ordinary student realises as the result of his own work that certain materials acted upon in certain ways with certain reagents can be converted into certain definite products. If properly led he follows the underlying chemical principles and if he has acquired a thorough grasp of those principles the educational value of this work is obvious. But valuable as is this work for the ordinary student it is woefully incomplete from the point of view of the technical student. It is not sufficient for the latter to know that from certain materials certain products can be obtained; he must realise that the value of his future work will turn entirely upon the question of yield and purity—in other words upon the cost of production. Why should not the "preparations" in the laboratories of the Technical Schools generally be made quantitatively? Many of the modern laboratory manuals dealing with preparations give the yields obtainable and, speaking from experience, I know that it gives zest to the work if the student is supplied with a known weight of raw material

and given to understand that the value of his results will be estimated by the yield and purity of his product. It is even possible to go further in "technicalisation" without in the least degree detracting from the educational value of the work. A series of preparations might be arranged in which not only the weight of the raw materials and of the final product were taken into consideration, but also the quantities of the various reagents used, and from these data, making sufficient allowance for the usual—not the laboratory—"working expenses," the actual cost of the product ascertained.

I know full well the objections that will be urged against this kind of work. The manufacturers will say that it is unreal, that it bears no manner of relationship to the actual factory results where the question of scale comes in, and that the cost of laboratory reagents or the value assigned to "working expenses" is too vague to lead to results of any commercial numerical value. The purely academic teacher on the other hand will say that such results, apart from their commercial inaccuracy, are of no scientific value as a discipline and teach no more than can be learnt from the ordinary preparation without any reference to cost. The "purest" of chemical teachers might even go further and say that the subject was being degraded by being put upon a commercial basis. It is needless to say that I do not admit the force of any of these objections or I should not be urging my case now. The results obtained, even if not comparable with factory results, may be made the basis of useful discussion in order to bring out the reasons for the discrepancy between the small and large scale operations. Quantitative preparations worked out from this point of view serve as most forcible object lessons by checking the reckless use of reagents and also by bringing home to the student on the *reductio ad absurdum* principle the worthlessness of his results if measured by the current commercial standard. In other words I believe it possible by introducing the economic element into the laboratory work of advanced students to make this work of more disciplinary value for the future "works chemist" than has hitherto been the custom.

Having, as it were, entrenched myself in this pit of heterodoxy I am prepared to meet the objections of the academic teacher by reminding him that in the most highly scientific of all "preparation" work, viz., the synthesis of new compounds, the whole truth is very seldom proclaimed. I hope that I shall not be accused of giving away the "mysteries" of my scientific colleagues, but it is very well known that the course of chemical synthesis very seldom runs so smoothly as to give a theoretically quantitative yield. In other words the synthetical compound may be the primary product or it may not, and in nearly all cases there are formed with the particular substance which we are aiming at secondary products which are just as much a part of the general chemical process as is the synthesised compound which we want. Now if these subsidiary compounds are crystalline or amenable to treatment by the ordinary methods of research we hear more about them, but if they happen to be tarry or resinous or indefinite we very seldom hear anything more about them. And so the synthetical achievement, as described by the discoverer, however brilliant as a piece of scientific work, is very often but a half-told story as measured by the absolute scientific standard. The tarry, resinous, and indefinite by-products are just as normal to the process as the definite compound which we isolate. If the latter should be a technical product the whole success of the manufacture may turn upon our being able to control the conditions of the chemical reactions so as to avoid or to minimise the formation of the subsidiary products and the degree of our success is a measure of our scientific achievement. If we look critically into some of the later developments of industrial organic chemistry from this point of view it will be seen that they are really marvels of achievement as pieces of purely scientific work. Now the success of a chemical reaction which results in a saleable product is only capable of being measured by a financial standard. The standard of scientific success and of commercial success can be expressed in the same terms—cost per unit of weight; there is nothing derogatory in extending

this principle to all preparation work given for laboratory practice whether concerned with technical products or not. The spirit of working at the highest economical efficiency must be cultivated in the Technical Schools, and the enormous importance of directing the resources of chemical science towards this end is best realised when the student is made to translate his results into commercial terms.

There is yet another possible extension of the principle of "technicalisation" in which I believe my heterodoxy is even more strongly pronounced. The mere statement of these views was at one time sufficient to insure being anathematised by both teachers and manufacturers, but as I shall probably never have a better opportunity of declaring the faith which is in me I claim forbearance while I state once again the case for large scale working in the Technical Schools. I am encouraged to do so by the fact that some of the contributors to the Birmingham discussion appear to have arrived at a similar conclusion and Prof. Donnan at Liverpool gave explicit utterance to the same view. To guard against any misunderstanding on this point I must however make it perfectly clear that my contention is for the introduction of the large scale practical exercise into the advanced stage of the preparatory training, while the plea put forward at Birmingham and Liverpool is for its introduction into the post-graduate or technological stage of the training. I do not know whether there is any real antagonism of opinion between us. It would of course be understood that my claim is only for comparatively simple large-scale preparation work as introductory to the more elaborate and advanced "technological" work proposed for the post-graduate course. At whatever stage however this kind of work begins the actuating principle is the same and has long been accepted by those teachers who have recognised the educational value of such work for those who are in training for chemical industry. The first difficulty which the college-trained student has to face when he enters a factory is his want of familiarity with large scale operations. His experience has been acquired with laboratory utensils and apparatus; he thinks in terms of grams and he finds himself in presence of plant dealing with hundredweights and tons. His beakers, flasks, retorts, and dishes have become magnified into tanks, vats, stills, jacketed pans, etc., and his gas burners have been replaced by furnaces, gas-producers, steam coils, and so forth. The laboratory failure which leads to the loss of perhaps a few shillings' worth of chemicals he now realises to be absolutely inadmissible in the factory when tens or hundreds of pounds' worth of materials are at stake. Can nothing be done in the colleges to make the student better prepared for this experience which he is bound to go through if he becomes a "works chemist"? It will of course be said that this kind of experience can only be gained in the factory and that no employer is likely to put a student fresh from college in a position where his inexperience is likely to lead to disaster. But if we as teachers admit the force of this argument, which is reasonable enough so far as it goes, I maintain that there is still scope for making a further advance in laboratory teaching towards the requirements of the manufacturer and so for providing the industry with a more efficient type of worker than was possible under the old system. My contention is, in brief, that with advanced students in the Technical Colleges the preparation work should be increased in scale so as to introduce an element of training in chemical handiwork. Lest I should be confronted with that awful bugbear of certain academic teachers, the working furnace run in connection with the metallurgical departments of one or two of the newer Universities, let me state at once that I am not now advocating the introduction of working models of special plant used in particular industries. The plea is for the handling of apparatus illustrating such general operations as are carried on in all factories—heating and cooling, evaporating, distilling, mechanical mixing, grinding, solution, filtration, etc.—on something more than the ordinary laboratory scale. The equipment for this kind of work is not very costly as compared with the cost of the elaborate machinery now used in engineering education. The contention that this kind

of experience unfits the student for factory work by familiarising him with fictitious representations of the real things has no real weight. The same argument was advanced in former times against the college workshop training of engineering students—that they were unfitted for their subsequent career by using tools and handling models which had no practical existence in the industry. I suppose every teacher of engineering in the country would repudiate this argument now. From our point of view I believe that a little experience of this sort, if properly directed, is of real educational value, and every Technical College worthy of the name should have a "chemical workshop" of the kind indicated. The teacher who allows the student to imagine that a few hours a week spent in preparing a few pounds or gallons of some chemical product will convert him at the end of his college course into a finished technologist is simply incompetent.

It must be clearly understood that this plea does not mean that the colleges should be expected to teach chemical technology in the strict sense—that is a quite distinct question; neither does it mean that *all* the preparation work should be done on this increased scale. It amounts in fact to nothing more than interpolating as a part of the laboratory training of the advanced student a certain number of hours' experience of a kind which cannot but render him better fitted for factory conditions. It is the extension to chemical teaching of the same principle which is now generally recognised in the mechanical laboratory training of the engineering student who is provided with working models from which he makes observations and takes measurements, and so learns fundamental principles irrespective of the particular piece of apparatus or model which he uses, and which may or not be like anything that he will meet with in his subsequent career as an engineer. More than twenty years ago I introduced this principle into our chemical curriculum at Finsbury, and although it has not been developed there to the extent that I should like, its soundness is borne witness to by the fact that a few of the newer Technical Colleges have equipped such "technical" chemical laboratories. I may particularly mention in this connection the Glasgow and West of Scotland Technical College.

Training in Collateral Subjects.

It is generally agreed that the preliminary scientific training of the works chemist shall comprise mathematics, physics, and mechanics, and I assume that the Technical Schools which are properly organised are provided with the necessary staff and equipment. It only remains for me to indicate a few of the practical difficulties which are experienced in carrying out this part of the work, because a better understanding of these difficulties by the teachers and the manufacturers may help to clear some of them away, or at any rate to lessen them.

In the first place it must be pointed out that there is no Technical School in this country which caters exclusively for the chemical industries. In general terms they are all schools of mixed subjects in which the engineering classes are generally predominant. In principle the teaching of these collateral subjects is the same as with the teaching of chemistry, that is to say, there is only a teaching of the general principles of the sciences concerned and no attempt at specialisation or true technological training. It is recognised in these other subjects, as in chemistry, that specialisation follows the general training. Now the teachers of these collateral subjects are, or should be, men of distinction in their respective subjects; that is to say, men who, superadded to their general attainments, have special knowledge in some branch of applied physics or of engineering, because these are the only teachers who are really in place in a true Technical School. That being the state of affairs, it is but natural that any bias which may perhaps unconsciously be given to the teaching of these other subjects is generally, I may say invariably, in other directions than towards applied chemistry. Of course it will be said that in principle there should be no bias; that the fundamental principles of physics and mechanics and such grasp of mathematical methods as is necessary for the proper understanding of these

subjects are the same for all departments of applied science. Theoretically that may be so and practically it is so up to a certain stage of rudimentary treatment, but sooner or later there is bound to come into the curriculum a development unfavourable to the chemical student and for a reason which does not appear to me to have been sufficiently taken into consideration. That reason is to be found in the circumstance that our subject, chemical industry, is already a highly specialised subject—much more so than the various branches of engineering, in which, however sharply separated they may subsequently become, the general preliminary training can be run on the same lines practically up to the end of the student's college career. In other words, the same chemical, physical, and mechanical training is sufficient for the future engineer at this stage of his education in whatever branch of the industry he may ultimately find himself. But the training in physics and mechanics which suffices to launch the young engineer upon his career cannot, in the nature of things, take the future works chemist so far into his career, because the engineering of chemical plant is quite a special branch of engineering, and practically all the engineering teaching in the Technical Schools is directed towards the civil, mechanical, or electrical branches of the industry. Even in pure physics, in which there is, so to say, a larger area of elementary groundwork capable of being occupied simultaneously by chemists and engineers, the divergence sooner or later tells in favour of the latter, because the physics of modern chemistry has also become more or less specialised.

These difficulties are well known to all who have had to deal practically with the education of technical chemists. They are partially met in various ways, such as by the interpolation of special lectures supplementing the general courses and developing the applications of physics to chemistry in those cases where physical principles have become of paramount importance. In the Universities of Birmingham and Leeds it has been found necessary to organise special courses of engineering for those students attending the departments of applied science other than engineering. It is not a difficult matter to arrange for the work of the chemical student in the drawing office to be of a special character, and my colleague, Professor E. C. Coker, has found that a course of drawing, which commences by exercises in tracing and pencil drawing from copies of the simplest pieces of machinery used in chemical works, can be readily expanded into a course of elementary design in which students are taught to make finished drawings from rough sketches. Chemical manufacturers will, I hope, support us in upholding the principle that the works chemist, even if he is never called upon himself to prepare plans for new buildings or plant, should at any rate have received sufficient practical instruction to enable him to understand a mechanical drawing intelligently and to co-operate with the works engineering staff with greater efficiency than if he had never had any training as a draughtsman. If this be admitted, there is no better period for such instruction than during the career at the Technical College; it is the one chance which the future chemical technologist gets during his student life of acquiring an art of great value in his profession, and an art which the older generation of chemists never had an opportunity of acquiring, for mechanical drawing was at that time considered an exclusively engineering subject.

My object in calling attention to this aspect of the technical education question is not only to make known more definitely to the manufacturers what we are actually doing, but also to enable them to realise the conditions under which the chemical student in the modern technical school receives his instruction in collateral subjects. Of course the ideal school from our standpoint should have its courses in these subjects laid down with a view to the special requirements of chemical industry, but under existing conditions this is obviously impracticable. The methods which I have indicated for dealing with this part of the training are confessedly of the nature of a compromise.

From Technical Chemistry to Chemical Technology.

I have thought it desirable to declare the educational policy of the Technical Institutions as understood by me,

not only because they have been left out of the recent discussions, but also because it would appear from many of the contributions to these discussions, that the actual work being carried on in some of these institutions in the required direction is not sufficiently known. Many of the proposals for the training of industrial chemists are quite familiar to us and many of them have been more or less realised in practice. It is of course possible that this work was known to the various contributors, but that they did not attach sufficient weight to the Technical Institutions as a power in the education of industrial chemists to refer to their work specifically. Perhaps there is some justification for this attitude—at any rate, nothing but good can result from the recent discussions if, in their light, we are led to re-examine our position in the schemes of modern technical education. I have frankly admitted that our finished product is a young man who cannot be regarded as a technologist in the strict sense required by this Society. It is only claimed that he has been prepared for a technological career. Can the Technical Schools or Colleges carry his training to a higher level? Can we turn out students more fully developed as technologists? I will not at present attempt to answer these questions from the point of view of the Technical Institutions in particular, because their consideration belongs to the general subject of ways and means, but in principle, and apart from any particular class of school, I have no hesitation in asserting that it is both possible and desirable to extend the college training far beyond this preparatory stage.

In making the foregoing assertion I am fully aware of the conflict of opinion on this subject. It must be realised that there are two distinct schools. The representatives of one school in principle say: Train a chemist as a chemist and then turn him into the factory for his "practical" (technological) education; this part of his training cannot be dealt with by any educational institution—it can only be acquired in the works. The adherents of the other school maintain that a training in chemistry and allied subjects—in other words, that the purely scientific education, however advanced, and admitting even the moderate amount of technicalisation here advocated, still results only in the production of a young man who has to begin his technological career very low down—practically from the beginning. Now these divergent opinions affect only the nature of the advanced training and not the question of period. Both parties agree that the preliminary training is inadequate for the student who is to become a works chemist in the best sense; the question really before us is: How and where can the educational period be prolonged with the greatest advantage? If it is maintained that the scientific education is all-sufficient and that the factory can supply the remainder, then the supplementary period would be devoted to advanced scientific work; we should be able to supply the works with more highly-trained chemists. On the other view it is held that the purely scientific training makes no provision for factory work—that as the student is nearing the commencement of his technological career his college work requires more specialisation in that direction, or, in other words, that the technicalisation of the curriculum should be carried to a higher level. This is the crux of the whole situation. Those among the teachers who are familiar with the requirements of chemical industry know that what is really wanted is a combination of the principles advocated by both schools of opinion—that the advanced training should be in the direction both of science and of technology. The practical realisation of this ideal is at the root of all the discussions which have been going on since the question of the training of industrial chemists was raised; it is undoubtedly the greatest difficulty with which the Technical Institutions have been confronted since the technical education movement was inaugurated. Partial solutions of the problem have been suggested from time to time, but these, in one form or another, are but modifications of that "sandwich" system which, however applicable to engineering industry, does not seem to be realisable in the chemical industries. Our manufacturers could not allow their works to be staffed by chemists who had to spend part of their time in the factory and part in

college. The problem would be simplified if we took the line of least resistance and divided our students for advanced work into two groups, which for brevity I will provisionally call "scientists" and "technologists." But is this desirable? Is this the course best calculated to supply our factories with the most efficient chemists?

Perhaps the best method of preparing the way for a better understanding on this point will be to follow out the extreme consequences of the two alternatives. According to one school, we should have a class of untechnicalised scientists; according to the other, we should have a class of unscientific technologists. We require either of these: we want scientific technologists. If the scientific chemist is accepted as all-sufficient, then by one stroke of the pen the whole work of the *bona fide* Technical College is struck out from the programme of modern chemical education. There was no necessity for the creation of a new class of educational establishment in order to train scientific chemists. If this is the class of chemist required, our factories could be supplied with any number of graduates from the Universities or other institutions preparing for degrees. But the technical education movement was really a revolt against academic training as preparatory for technology; it has long been admitted, if not explicitly stated, that such a curriculum is imposed for the ordinary science degree is not particularly well adapted for those who have an industrial career in view. Those who hold extreme views have declared that such a course of study is quite unfitting for such purposes. Indeed, some of the newer Universities have recognised the inadequacy of the ordinary science degree by allowing certain branches of applied chemistry to take rank in the curriculum for degree-winning purposes. This seems to me quite sound in principle, but the application is necessarily restricted by the particular branches of applied chemistry for which the University is equipped. As far as it goes this new departure, however, is such a distinct advance in the right direction from the point of view, that I have no hesitation in commending to the notice of the representatives of the particular industries concerned.

But this is a digression into a part of the subject with which I am not now dealing, viz., the functions of a University as a Technical School. The point that the manufacturers are called upon to consider is what kind of advanced training shall follow the preparatory training. If you are satisfied with a youth who has spent his three years at a Technical School, well and good—it is your business, not the teachers'. But most of us teachers—indeed certainly those who have had any experience in chemical manufacture—think that you ought not to be satisfied with this qualification. The chemical technologist is a chemist *plus* a great deal more—so very much more that, even with the most approved methods of instruction, we can do no more than place our finished student on the threshold of his industrial career. If you are satisfied with this moderate degree of training it may be justly urged that the modern technical education movement has not taken us as a manufacturing nation very far beyond that state of affairs which that movement is intended to remedy. Consider by way of comparison the qualifications expected from those who are being trained for other branches of applied science, and it will be seen that you have pitched your requirements at too low a level; you have handicapped yourselves by taking youths whose education, from your point of view, is what biologists would call a state of arrested development. In your interest and in the interest of chemical industry it appears to me that there is a gap between the preparatory training and the factory work which it is the duty of the educational institutions to bridge over. The recognition of this principle is at the basis of all the recent discussions, irrespective of the class of school where advanced training is to be given, and irrespective of the precise nature of that training.

Let me state at once—of course only as an expression of personal opinion—that for many years I have been of the opinion that the factory is not the proper place for beginning technological training. This I know is opposed to the views of those teachers who advocate the all-sufficiency of a pure scientific education. Many teachers who hold

this view have stated explicitly that if a student is thoroughly trained in scientific method and habit of thought the technological part of his training becomes a comparatively simple matter. I think these teachers make light work of a serious educational problem; they underestimate the requirements of chemical technology. Chemical manufacture is an art as well as a science, and an art of such complexity and carrying with it such heavy responsibilities if approached with imperfect preparation, that the student who has been trained in science only is to all intents and purposes a mere novice. I am aware that a few cases can be quoted in which a student trained in pure science only has gone into a factory and has at once made his mark as a technologist. Instances of this kind are sometimes referred to as proving the all-sufficiency of the pure science training. According to my experience, such cases are quite exceptional, and when critically examined resolve themselves into the occasional discovery of a technological genius or into the presence in the factory of a staff already competent to work out the ideas provided by the scientifically-trained chemist. The sporadic appearance of this rare combination of the scientific and technological faculties cannot be used in justification of the omission of all technological training in the Technical Institutions. I have for so long been preaching this doctrine of the necessity for higher training before entering the factory that it gives me peculiar pleasure to be able to quote a passage from that address to the American Chemical Society by our former President, Dr. William H. Nichols, to which I have already alluded. Speaking of chemical engineering in America, Dr. Nichols says:—

"Thirty-five or forty years ago work coming under this head was in this country performed almost exclusively by practical men brought up in the works, whose deductions were the result of experience unenlightened by theory. It was, of necessity, somewhat crude, but good enough for practical purposes while every chemical manufacturer was in the same boat. The advent of the college-trained man changed all this, and the uneducated engineer has been gradually relegated to the background, and for obvious reasons. The advantage the college-trained man had was in his knowledge of the theory of chemistry. His disadvantage was his utter lack of engineering knowledge to enable him to apply it practically. The theory was of more value than the rough engineering without it, for engineering ability of high order has long been attainable, and thus, theory could have a respectable application. . . . In the chemical works, however, where the highest application of the theory is aimed at, chemistry should be the guide and engineering the servant. If the chemist can also be the engineer, so much the better, and so much more likely will he be to bring his theory to fruition."

I only give this extract, but I commend the whole address to the serious consideration of both teachers and manufacturers. The position assigned to college training in America is virtually that chemical industry has thereby been lifted out of its empirical stage and placed upon a scientific foundation. When, therefore, I declare against the factory as a suitable training ground for the initiation of the student at the outset of his technological career I have in mind certain considerations which, with all diligence and I hope without offence, I may venture to submit on this occasion.

The Necessity for, and Nature of, the Higher Training.

In the first place, from what I know of the actual state of affairs in some of the chemical factories in this country, it would be very unfortunate from an educational point of view if a college-trained student entered into such works under the impression that he was going to be converted into a finished technologist. If his training had familiarised him with what was going on elsewhere in the particular branch of industry into which he had entered he might even be justified in declaring that his technological outlook was a very gloomy one—that even his college education had enabled him to realise that he was amidst antiquated plant and imperfect or possibly obsolete processes. Under such conditions the continuation of his education as an industrial chemist instead of being a development might be regarded as a retrogression. Instead of passing directly

from the college preparatory course into the works he might reach a higher level by continuing his advanced training in the Technical College. That is the state of affairs regarded from our platform as technical educators. Now I dare not venture to suppose that the conditions which I have outlined prevail to any great extent in our chemical factories—at least I hope not. But it will not be denied, even by the most patriotic of our manufacturers, that there are works which could not by any stretch of patriotism be regarded as ideal training grounds in chemical technology. And even in those factories where better, or possibly even the best, conditions prevail, it is still doubtful whether it is desirable for the student who has only undergone a preliminary training to begin specialising too early. I invite attention to this aspect of the case from the educational point of view.

The manufacturers must credit us with the desire of providing them with the very best material that we can turn out under the conditions specified in this address. We ask them further to believe that the motive power of our work is the same as theirs—the advancement of British chemical industry. Some of us are trying to effect this object from the educational side, others from the side of research. To very few is it given to be placed in such fortunate circumstances as to be able to promote advancement by both modes of attack. There might be many more if our educational institutions were properly organised, but this is connected with the general subject of the wastage of research faculty in this country which I dealt with two years ago. Now the majority of teachers who know the requirements of chemical industry will agree that the preparatory curriculum, however thoroughly it may be carried out, still leaves the student with a very limited mental horizon. He is but a youth of say 18 or 19, at the most impressionable period of his life. If he forthwith enters a factory his outlook is, by the very nature of his occupation, narrowed down by the requirements of his own industry. In a comparatively short time he settles down into a groove; he is apt to become a purely routine worker, no doubt of immediate use to his employer, but lacking that mental elasticity and expansiveness upon which the future development of his industry depends. We maintain that this is not the best kind of chemical technologist to develop in the factories with a view to the future prosperity of our chemical industries. We know too well the deadening effect of getting into a rut; a few years of specialisation starting from a too narrow general training produces just that type of man who not only fails to recognise progress in his own domain, but who, as he gets older, is generally hostile to anything approaching innovation. That is the kind of man who has crippled many of our industries in the past and that is why we are advocating the extension of the period of college training as an educational discipline. We want to plant in the factories young men with breadth of view and plasticity of mind—men who by virtue of their scientific training are able to follow the course of research and to appreciate all discoveries bearing in the remotest degree upon their industry. Our contention is that chemical industry requires the services of men who are not only apt pupils capable of rapidly mastering the *technique* of the operations going on in the factory, but also capable of teaching the factory where necessary. We want to add to your resources men, not only competent to carry on your present manufactures, but also imbued with the spirit of development. If I may use a simile, it is the dynamical and not the statical chemist who is wanted in our factories. We hold the view that the best way of achieving this result is to broaden the basis of technical education by insisting upon an extension of the training beyond the preparatory stage. You may perhaps secure the services of works chemists more cheaply by taking them at this stage of imperfect development, but our view is that in the long run this will prove to be false economy. If the manufacturers and the teachers will arrive at a *concordat* on this point we think that there will have been achieved one of the greatest advances in technical education ever made in this country, for unquestionably the stress of competition which we as a manufacturing nation are now feeling, and which is bound to become

more acute with the progress of discovery, has fallen with special severity upon many of our chemical industries.

The ideal which we are striving to attain is, I imagine, made sufficiently plain by the above statement of policy. How far we can or shall be in the future enabled to realise this ideal depends very largely upon the support which we receive from the representatives of chemical industry. The responsibility which rests with our manufacturers with respect to the future of chemical industry in this country is assuredly a very grave one. That future according to our view, is ultimately dependent upon the development of education and the promotion of research both in pure and in applied chemistry. I have no desire to pose as an authority on that most intricate of economic questions—the causes of industrial progress or decline; but with respect to chemical industry, I believe I am voicing the opinion of the teachers in general when I say that fiscal policy or patent legislation or any other external influences which may or may not be our common cause are but secondary considerations. We believe, for whatever that belief may be worth, that the prime factor of prosperity and of progress—discovery and invention, and as the attitude of mind which develops that factor is education in the broad sense, we place the consideration of educational policy in the front rank.

On this view it is but a short step to the further conclusion that the training of our industrial chemists at present carried out falls short of the ideal which has been set up as our standard. It is for this reason that I attach so much importance to the recent discussion. The teachers and the manufacturers, or at any rate, considerable number of them, now appear to realise that some further development of technical education in this direction is urgently needed. The discussion resolve themselves in essence into the question of *what* and means for achieving the desired end. All the proposals that have been made in connection with the higher or supplementary training, from the time of Mr. Beilby's address of 1899, down to the latest contribution in our Journal, have taken it for granted that this training is to be of a technological character. Many speakers and writers label it unhesitatingly "chemical engineering" and some add the business or economic treatment of industrial chemistry. I do not propose handling the latter part of the subject now for want of time, but apart from questions of detail with respect to technological curricula, it is clear that the voice of chemical industry is against the all-sufficiency of a purely scientific training. With this opinion I concur, but in giving my adhesion to the views of manufacturers on this point, it must not be supposed that I consider the educational problem thereby solved. If it were admitted that the preparatory scientific education followed by a technological curriculum was all that could be desired, I should have to express dissent, because on this view no scope is given for further training in science. This seems to me a serious omission. The student is not "finished" after a three years' course—not even if he has taken his B.Sc. If, say as a University student, he were going on to a higher degree he would be expected to show evidence of originality by presenting an original investigation. That is of course a sound principle and is now generally recognised. In some Universities original work in some branch of applied science is allowed to rank, and that also is a sound principle.

Now my contention is, and has been for more than a quarter of a century, that the development of the research faculty is a matter of precisely the same order of importance in the education of the industrial chemist as it is in the education of the academic chemist who is in training for let us say, a professorship. Therefore during the supplementary period following the preparatory training there must be given opportunity for research work. No institution of whatever rank professing to train chemists for our factories is doing its duty to chemical industry unless every advanced student is given that opportunity; it is his only chance during the whole period of his educational career. I see no way of getting it in anywhere else. The average student is not fit for research until his general preparatory training has been passed through. I do not believe in forcing original

ork prematurely upon the unprepared student, but I most strongly insist that every student who is prepared could be given his chance. It is immaterial under ordinary circumstances whether the piece of work undertaken is in pure chemistry or in applied chemistry; is the principle of research as an educational discipline the highest value that is being advocated. There are cases where a student is professedly training in some special industry; his research would, in these circumstances, naturally be made to bear upon his future work—it would be an investigation in some department of applied chemistry. But points of this kind are subordinate to the general principle. The kind of research I naturally depend very much upon the particular piece of work going on in the institution and the special "atmosphere" created by the teaching staff.

As the necessity for research as a part of advanced technological training may be challenged by some manufacturers (I do not think the teachers will oppose my intention), it may be desirable to explain somewhat fully what our position really is. As a typical expression of opinion on the part of a manufacturer, I will quote a passage from Dr. Beilby's recent address to the Association of Technical Institutions. After insisting upon the necessity for creating an environment of research in the colleges with which he was dealing, he goes on to say:—

"I do not put forward the plea that research is a necessary and desirable element in the training of all students, for I am still unconvinced on this point. Indeed I am under the impression that many of the less successful students and graduates in science whom I have met have been seriously injured through having been encouraged the idea that the cultivation of original research is the duty of every student of science. The real pioneering work will never be done by mediocre men. . . ."

This statement would at first sight appear to be directly opposed to the views which I have just put forward. In reality, however, there is no divergence of opinion between us. Having had the opportunity of discussing this point with Dr. Beilby, I learn that, on his part, he was referring to premature research work placed upon students during their preliminary training. I agree with me that research, or, at any rate, opportunities for research, should be given during the advanced training. That is all my contention.

It would, I imagine, be quite superfluous for me to state once again the arguments in favour of research in educational discipline; such a plea from me would be nothing more than reiteration of views expressed over and over again during the whole period of my career as a teacher. But the precise bearing of the research training upon the question now under consideration—education of industrial chemists—is a subject upon which there is more to be said. It is claimed that if we are to do anything more for our future works chemist than to give him a preliminary general training, he should be made to show what stuff he is made of by giving him as a part of his advanced training some piece of work which he can do for all the knowledge, originality, and resourcefulness which he may possess. That is to all intents and purposes the research, whether it leads to any result of sufficient importance to publish or not. In the case of research for educational purposes it is the discipline and not the result which we have in view. There has been much confusion on this point. Some teachers who have seen research work have argued as though the production of some publishable original memoir were the sole criterion of success and that if no such work is produced it indicates a failure of the method. They have confused that kind of work which we may reasonably expect from the students and teachers with the educational research which we expect of the students, which may or may not lead to publishable results. Even a negative result following an attempt to work out some particular problem has educational value. Therefore I repeat, every student should be given his chance. It is the opportunity—the only opportunity which the teacher is likely to get of selecting for chemical industry, a particular faculty which from our point of view is of the utmost importance. We all know that this faculty

of originality is rare. That is one of the very strongest arguments that can be used for giving the teachers the opportunity of finding out who among their students is thus endowed and who is not. It is only when all are given the chance that we can find out who is above the standard of mediocrity and who may therefore be developed into a "pioneer." The necessity for giving such opportunity will appear more clearly when I point out that the research faculty is not necessarily associated with aptitude in acquiring knowledge or in passing examinations. We all know instances of brilliant careers in the preparatory stage followed by mediocrity or failure when the test of originality is applied. So also could we name brilliant investigators whose work in the preparatory stage showed no evidence of superiority. The supplementary advanced or technological training should do for industrial chemistry what the post-graduate training does for academic chemistry: it should enable us to sort out the different orders of faculty. A few would be found capable of development as research chemists; a larger number as chemical technologists.

I can hardly expect that this plea for the general recognition of research as an educational discipline will lead to any immediate result. We move very slowly in this country and not always surely. It will be said that it is impracticable—that it is an ideal incapable of being realised in the Technical Institutions. That may be so; as the majority of these institutions are at present constituted, and in the present condition of technical education in our subject, when it is only with the greatest difficulty that we have succeeded in getting recognition even for a three years' course of preparatory training, it may be an ideal difficult to realise practically. But we must formulate our ideals, if only for the future. There are unfortunately so many unrealised ideals with respect to the higher training of chemical technologists that one or two more added to the heap will hardly increase its elevation to a perceptible extent. I am old enough to remember the time when even the highest academic distinction could be won as the result of pure book knowledge with no particle of evidence that the candidate was capable of extending the boundaries of his own subject into the region of the unknown. If this state of affairs has been remedied to a great extent in the academic world, how much more necessary is it in that most practical field of industrial chemistry!

If the manufacturers will recognise this phase of technical education another great advance will have been made. Both the teaching and industrial interests will gain by such recognition. In the first place let me remind you of the lament which I uttered two years ago respecting the failure of the modern Technical Institutions taken as a whole to have given anything approaching an adequate account of themselves as centres of research in view of the teaching staffs which they possess. It may be necessary to point out that I was at the time obviously concerning myself only with the question of research in pure science and not in applied science. Prof. W. M. Gardner in his address to the Yorkshire Section last November* has made this point quite clear, but I am glad of the present opportunity of referring to it again, because I have been misunderstood by a distinguished former President of the Association of Technical Institutions, who defended these institutions on the ground that they were carrying out a lot of industrial research which never saw the light of publication.† Whether that be the case or not in chemical industry is a matter which concerns this Society in particular and I propose dealing with it subsequently. With respect also to the output of research in pure chemistry, I am extremely glad to be able to state by the way that there are marked signs of improvement in this direction since my address to the Chemical Society. Now, one of the reasons why chemical research, either pure or applied, has not been placed in the Technical Institutions in that position which we think it ought to occupy, is because the chemical manufacturers have not made their voices heard. Possibly they do not believe in its efficiency

* This Journal, Vol. XXVIII., p. 13. (Jan. 15th, 1909.)
† "Education," March 6th, 1908, Vol. 8, p. 185.

as an educational discipline—perhaps they have not considered the matter sufficiently to give expression to their views. At any rate that is the quarter towards which we look for help, and if those manufacturers who accept this plea will declare their faith, it should have more effect in raising the whole level of chemical industrial training in the Technical Institutions than any amount either of pleading or of denunciation on the part of the teachers. Speaking freely on behalf of the latter we feel that for many years our voices have been crying in the wilderness. I rejoice to find that Dr. Beilby, in his recent address, has given no ambiguous pronouncement in favour of developing the institutions in this direction. I will go further and say that if they do not give their staffs as well as their advanced technological students opportunities for such work they are failing in their mission as educational establishments. This perennial output of students who have not got beyond the preparatory stage is, I am afraid, having a depressing effect upon the teaching staffs, who cannot but feel that some higher educational platform must be reached if their work is to produce any serious effect upon chemical industry. We may even be excused if we sometimes show signs of impatience when, after twenty years or so of "technical education," we find ourselves still hammering away at preparatory work and no provision for "technological" training in the sense understood here.*

And now if it be asked what the admission of this principle really involves from a practical point of view it simply amounts to this—that every student who has completed his preliminary training should at the discretion of his teachers be given an opportunity of taking part in research work. I do not urge that all students are by nature endowed with the necessary faculties. But I do most unhesitatingly declare as the result of very long experience that these faculties are of much more general occurrence than is usually supposed. If this belief is correct it follows that the omission of research from our educational curricula means a loss to our industry of a class of chemical technologists of which we are in particular in need—the man who has been trained in scientific habit of thought by the most effective of all known methods. There may be good technologists without the faculty of originality: there are excellent routine men running our factories most effectively, and our educational institutions should have no difficulty in keeping up the supply. But the routine man is only effective as long as the conditions remain unchanged. Let the processes with which he is familiar become changed by fresh discovery or displaced by newer and better processes, then the routine man becomes helpless. Had he entered the works with a good drilling in that mental attitude which is covered by the term "scientific method" he would be more able to cope with changing conditions; if his faculties have never been developed in that direction his chances of survival under changing conditions are reduced to a very low figure. Now we want chemical industry to employ chemists who will not collapse under the stress of competition, and it is not mere knowledge that will most effectively equip such men—it is *faculty* as well as knowledge that is required, and the exercise of originality under skilled guidance during the plastic period of studentship is the only method of developing that faculty. Those who are given an opportunity for undertaking this work could soon classify their students according to degrees of originality. I do not believe that out of an advanced class any considerable proportion would be sent down as having no research faculty at all.

In advocating the introduction of research into the advanced curriculum it must be most clearly understood that we are not contemplating the "research chemist" as defined in this address. He comes under another category. We are now considering only the higher education of the works chemist and the importance of research in relation to his advanced training. The actual state of affairs in the educational institutions

which would have to be faced if this most important principle were conceded need not be of a very alarming character. If it is admitted that some advanced training supplementary to the preparatory course is essential, and if it is further admitted that science is to form part of that advanced training, then the advanced laboratory work from, say, the fourth year onwards, could be made to include experimental investigation either in pure or applied chemistry. If by such means there happened to be discovered a student who had special gifts as an investigator that is the man to develop into a "research chemist." But whatever the ultimate career of the student may be—whether he is enabled to devote himself to research for industrial purposes or not—the experience gained would be of such a character that his services to chemical industry would be of a very much higher order than if he had never had such experience. If, as so frequently happens, after entering the factory, he never has a chance of conducting any research in connection with his industry, his scientific grasp of his subject would have been widened so that he would be in a better position for appreciating what advances were being made by others and so of acting the part of a scientific intelligence officer taking note of such discoveries as bore upon his work or threatened to weaken the position of his factory. It is only the man who has been through the research mill himself who can fully realise the bearing of research whether in its "pure" or in its industrial aspects. It is such works chemists that we want to receive the support of the manufacturers in producing in our educational institutions. That the institutions themselves would benefit enormously by such development into schools of research is sufficiently obvious, but the consideration of this point is part of the general question of existing educational resources.

It may perhaps give a more definite shape to the plea for an extension of the educational period beyond the preparatory course if I put the case into concrete form. If the chemical training is, by concession, continued into the advanced curriculum, what kind of chemistry is to be included in the course? Speaking from experience I should say that the development ought to be in those subjects which the preparatory course has excluded for want of time or for other reasons. Such subjects are, among many others, gas analysis, especially of the "technical" kind, valuation of fuels, the theory and use of physical instruments employed in chemistry such as the pyrometer, calorimeter, photometer, polarimeter, spectroscope, refractometer, viscometer, colorimeter, etc. It is unnecessary to enlarge upon this point, every teacher knows all about it. I only mention it here because I want it to be realised what a wide field for further training there is in the laboratory after the preliminary groundwork has been laid. Some of this kind of work can be done during the third year, but it is not possible to get very far in the course of one session when other subjects are also claiming attention both in the laboratory and lecture room.

Chemical Technology as an Educational Subject.

Turning now from the scientific side of the advance work we have to consider the question of technological training. This may be regarded as one of the most important of all the subjects which we have to deal with either as teachers or as manufacturers. Its importance is unquestionable, if only on account of its neglect in the past: it is in fact the fundamental question which tacitly or avowedly is at the basis of all the discussions which have taken place both recently and in former times. But, in spite of its importance, this subject does not require detailed consideration here, because at this stage it is only the question of principle which concerns us. If the principle be admitted the details can be filled in without much difficulty. To me one of the most encouraging aspects of the recent discussion in the provinces is that there appears to be a very general opinion in favour of such training. The proposals have it is true, come chiefly from the University side, but this is immaterial. We have come to the parting of the way the purely academic teachers, who have declared in favour of the all-sufficiency of pure science as a preparatory

* See a paper by the writer read before the Royal Photographic Society on Feb. 2nd, 1892, in the "Photographic Journal" for that year, p. 152.

chemical industry, must realise that the manufacturers as a whole are against them. They must take note of the fact that the majority of teachers, whether in Universities or Technical Institutions, who have taken part in these discussions have conceded or have unhesitatingly declared that some technological training competing the preparatory courses with the factory work is a necessity of the time. I cannot too strongly emphasise the importance of these opinions because, be it remembered, the gap has never yet been adequately filled up in this country. It is the weakest point in the whole of that educational machinery which we have been trying to put in for the purpose of training "technical" chemists. Attempts to move in this direction have been more or less paralysed by the teachers declaring for pure science and by the manufacturers proclaiming that it is impossible to teach chemical technology in the technical institutions. At last light seems to be breaking into this very obscure domain, and a little further discussion may help to disperse more of the obscurity. It is beginning to be perceived that when a technical education of the works chemist is really considered it is the technological training which is really wanted. It is remarkable that we have been so long living at this point. I have indicated the main causes, and I need only add that an enormous waste of energy has been the result of concentrating attention too narrowly on the scientific side of the training—a point which can be dealt with in any properly staffed and equipped technical institution and which really requires no special discussion if the necessity for this training is admitted, as it now is. I will venture to remind you that it is just a decade since this very question of the technological training of chemists was discussed in Germany, when I endeavoured—I must admit unsuccessfully—to stimulate action in this country by calling attention to what was going on over there.*

And now we are, I think, in a position to face that we have to deal with a certain class of teachers—chemical technology in educational institutions. What does it really mean? The broad answer to this question has been given over and over again and I can only paraphrase former statements. It means *generalised* chemical engineering. It does not mean the *technique* of any particular industry, but a knowledge of the chemical, physical, and mechanical principles underlying the construction and working of the machinery and plant of general use under various modifications in all branches of chemical industry. It is a composite subject, part of which is pure engineering—such, for example, as power production and distribution—and part of which is specialised engineering, such as the nature, source, and properties of materials used in the construction of chemical plant. It is in its practical aspect a development and expansion of that "technicalised" chemical training, comprising the *economic element*, the initiatory stage which I have advocated introducing into the preparatory course. It is the extension and elaboration of the technical laboratory work to a higher level. It is not chemical engineering in the narrow sense, because that is generally understood to mean the construction and working of the factory machinery. It is the addition to the purely chemical training of that general scientific knowledge of the principles of construction and working of plant which enables the works chemist to co-operate intelligently with the works engineer or, if he should find himself in a factory with no special engineering staff, to design and run the plant for himself. It is a specialised branch of engineering knowledge added to a scientific grasp of the principles of chemistry. Some educationists would include a training in the principles of such business operations as the keeping of factory accounts, working expenses, etc. I see no objection to this if time can be found. The general object is to prepare the student for the special technology of the industry in which he finds himself. This is the educational development which has once more been brought under the notice of the manufacturers; this is the chemical

technological training which was under discussion in Germany ten years ago and which has been recently developed in America. If this really is an educational requirement of the age—as we teachers believe it is—let the manufacturers say so; it would give an impetus to the work of both the Universities and the Technical Institutions. If the principle is not admitted, let the voice of chemical industry be heard on this side also. We want to know exactly where we are. Only, be it remembered, that no expression of opinion which centres round the particular industry with which the manufacturer himself is identified is of any practical use in framing educational policy. We have to cater for chemical industry in the abstract and not in the concrete. If it be urged that each branch of chemical industry requires special treatment and each its own special school, then we shall have arrived at an *impasse* and the discussion will have been taken altogether out of the domain of practical educational politics.

If the technical education of the works chemist is to be extended in the direction indicated it may be useful to point out the nature of the difficulties which will have to be faced. I am not now concerned with the question of institution—whether University or Technical College; that is a question of ways and means. It must be understood that by difficulties I do not necessarily mean objections, but obstacles which can and ought to be overcome if we are seriously prepared to advocate the new departure. In the first place there is the question of time and curriculum. If the preparatory training takes three years it is not too much to ask for an additional two years for the advanced course. A total course of training of five years is not a very heavy demand in view of the nature of the requirements of chemical industry. It takes seven years to produce a qualified doctor and five years a qualified lawyer or chartered accountant. The answers to the Birmingham queries and the views expressed in the discussions there and at Liverpool make it clear that the minimum period of five years is generally recognised as essential; if it could be extended to six or seven so much the better.

With respect to the curriculum it is only necessary now to lay down the general principle that the course should consist of higher scientific work, including research as advocated, and chemical technology as defined. An immense amount of difficulty has been placed in the way of this development owing to the discordant views concerning the nature of the technological training. But this discordance really only affects questions of detail and not of general principle. Indeed the time is scarcely ripe for formulating any detailed scheme of chemical technology for general acceptance; there may be many schemes, all equally good, and each suitable for a particular district or a particular institution. But the materials are at hand and have been available for a decade or more. Again I invite attention to Dr. Beilby's address of 1899 and the discussion thereon; the scheme prepared for the Technological Examination of the Institute of Chemistry will give a very good notion of what is required. The papers leading to the discussions at Liverpool and Birmingham and also the discussions in these Sections bring out the general nature of the subject. If there is any doubt as to what constitutes chemical engineering look at the late Mr. George Davis's "Handbook," the first edition of which appeared in 1901; look also at Dr. Grossmann's "Elements," published in 1906, and at Dr. Nagel's "Mechanical Appliances of the Chemical and Metallurgical Industries," published last year in New York. Consult further the classical works on special industries, such as those of Lunge and many others. Among foreign publications Wolfrum's "Chemisches Praktikum" with its atlas will give a very good indication of the requirements. The list could be extended indefinitely. It is as unreasonable to declare that chemical technology cannot be handled as an educational subject as it is to suppose that a student can be profitably launched straight into the factory with no other preparation than a training in pure science.

The objections so frequently urged against the introduction of chemical technology into educational establishments are resolvable into the two difficulties, equipment

* See "Nature," Feb. 16th, 1899. Also Dr. Beilby's Address to this Society in 1899, already referred to.

and staff. But, as has just been said, difficulties are not necessarily insurmountable obstacles. With respect to equipment I have already pointed out that there has been great want of discrimination in discussing this question both by teachers and manufacturers. The practical realisation of a course of instruction in chemical technology, as in other subjects, means laboratory work and organised courses of well-illustrated lectures. If visits to works could be made part of the instruction so much the better, but this, as already stated, is not generally practicable. The "laboratory work" in technology is of a different order to that given in connection with the scientific side of the curriculum. It is on a larger scale and involves the use of various pieces of machinery or working plant. In fact for "laboratory" we must read "chemical workshop." Now the outcry that is raised, when instruction in the use of large-scale plant is advocated, is partly on account of initial expense and partly on account of the impossibility of any educational institution keeping itself equipped with the latest forms of plant used in the various industries. With regard to expense, I may point out once again—even if I incur the charge of unnecessary repetition—that the general elementary operations carried out in chemical factories can be illustrated in the college "chemical workshop" at no greater, even at a less, cost than the mechanical principles underlying engineering practice can be and are, in fact, illustrated in the college mechanical laboratory by working models or actual machinery. If the expenditure is justifiable from an educational point of view for the training of engineering students surely it is equally justifiable for "technical" chemical students. It might as well be urged by objectors to the system that college training is of no use for engineers because the students cannot build a locomotive or construct a bridge in the workshops. No teacher of engineering in any of our educational institutions would admit the validity of this objection.

There has, as I have said, been a want of discrimination concerning the equipment for chemical technological work, which has hampered the development of the subject in this country to a most regrettable extent. Because the running of a full-sized furnace by a University department of metallurgy is considered too costly as compared with the educational results achieved—a contention for which there may be some justification—it is argued that no factory operations can be illustrated in a college workshop. Because it is not practicable to work a sulphuric acid plant or to run model alkali works in an educational establishment, it has been declared that chemical technology is beyond the scope of education. The objections have been of far too sweeping a character. Both teachers and manufacturers agree that it is undesirable to attempt instruction in the *technique* of a particular industry, but it does not follow that in some industries we cannot get much nearer to the actual factory operations than in other industries. In certain specialised departments of technology, such as dyeing, preparing and bleaching textiles, and in the leather industries, in photography and photo-technics, in electro-metallurgy, &c.—all of which we claim as branches of chemical industry—the practical operations can be and are carried out in educational institutions, and the scientific principles illustrated by the actual processes which the student conducts with his own hands. If such teaching is not allowed to degenerate into pure handicraft—and no competent teacher would allow this—the technological preparation for the particular industries concerned is of the greatest value. To mention a specific case by way of illustration:—Two of the Guilds of the City of London, the Clothworkers' and the Skinners', have founded departments of applied science in the University of Leeds, one for tinctorial chemistry and dyeing, and the other for the leather industries. Both these departments are equipped for "technological" training in the respective subjects, and would, in fact, be regarded by the Professors of these departments as incomplete without such equipment. With respect to the technological laboratory work, Prof. Procter, in answer to some questions which I submitted to him last year, states:—

"While different manufacturers will differ in the extent to which manufacturing processes can actually be reproduced on the small scale, it is generally possible to teach

a good deal of practical importance, and even to give much special technical knowledge which cannot be acquired in the works, where every operation must be conducted with a view to profit, and no deviations from what is supposed to be the best conditions are possible. I do not consider that leather manufacture is by any means one of the easiest to carry out on the very small scale necessary in a University, and the difficulties are increased by the fact that it is largely a mechanical as well as a chemical industry. We succeed, however, on the small scale, in turning out every description of leather, of a quality which we have no difficulty in selling at a price which averages about that of the actual materials employed and which is equal to that obtained by many similar leathers commercially produced. We have also abundant evidence that our really promising students very rapidly adapt themselves to working conditions on the large scale, and, after a reasonable amount of experience, form a very valuable type of practical man."

The same principle is recognised in the Municipal Technical School at Manchester, in the Glasgow and West of Scotland Technical College, in the Bradford Technical College, and in all the Universities which have developed departments of applied science. *The principle of technical laboratory or workshop training is a sound one; its criticism has not weakened the case which has been made out in its favour by pointing with scorn to certain extravagant developments; neither is it fair to read into the principle certain conclusions for which the principle is in no way responsible, and then to make use of these illegitimate deductions for denouncing the principle.* Over and over again we are told that the conditions existing in a chemical factory cannot be imitated in the College. We ever pretended that they could be? I certainly have never put forward such a claim, neither can I find it in the writings of any teacher of authority who has dealt with the education of technical chemists. So also we are told that the costly working models of plant in a few years become obsolete and are fit only for scrapping. But we ever advocated the maintenance of a chemical technological laboratory in a state of complete equipment with all the latest forms of plant? There is no such claim; any of the schemes of chemical technology that have been put forward either recently or in former times.

But granting the possibility of meeting the requirements of the chemical manufacturer by some adequate scheme of technological training in continuance of the preparatory course, there is still the question of the staffing of the educational institutions to be considered. This is confessedly a difficulty under existing conditions. If technological laboratory work is to be included in the curriculum there must be "instructors" in charge of such laboratories, and here the purely pedagogic type of teacher would be worse than useless. The only instructor of value for such work is the man who has had factory experience and is familiar with the practical working of chemical plant. His function in the chemical department would be analogous to that of the "workshop instructor" of the mechanical department. Another difficulty, which is a very real one, is the engineering course. It is, of course, familiar knowledge to manufacturers that the engineering requirements of chemical industry are of a quite special character. In other words, chemical engineering is a specialised branch of engineering, as has already been pointed out when considering the training in collateral subjects. The advanced engineering training of the future works chemist to be of real use should therefore be in the hands of a professor who has himself specialised in this direction. Such men are rare in this country; the few expert practitioners who could be named are probably better off as private consultants than they would be if they transferred their services to an educational institution.

Although the staffing of a University or Technical Institution for training in chemical technology as defined is thus hampered by the initial difficulty of finding competent teachers, it must not be forgotten that the subject has never yet been properly developed in this country from the educational point of view. If systematic instruction in chemical engineering and chemical technological laboratory work were generally recognised as essential for the

ing of the works chemist, I have not the least doubt that table teachers would be forthcoming. Here, again, the of chemical industry should surely make itself heard. do not mean to imply that this Society should become active educational body, but if the manufacturers agree principle with the plea for chemical technological training which I have advocated, they would do good service the cause by bringing their influence to bear upon the educational institutions in their own districts. I may not out that in those isolated cases where, as at Glasgow and Manchester, some progress in the development of a chemical technological curriculum has been made, it is only due to the influence of those manufacturers who have taken an active interest in educational work.

Research in relation to Chemical Industry.

So much has been said by myself and others of late in connection with the above subject that it may be thought that the theme is exhausted. In view of its intimate relations with the question of the education of technical chemists it may however be of use if I attempt to clear away some of the misunderstandings which have hitherto prevented both teachers and manufacturers from dealing with this question in a manner profitable to either party. We have not now to consider research in an educational discipline—that point has already been discussed. We have to deal with the subject of research in connection with the advancement of our industry, in which it must be clearly recognised at the outset that it has a twofold bearing. It is essential that current processes should be constantly under investigation in order to keep them in a state of perfection or to improve them where possible, and it is no less essential that pioneering research should be carried on with the object of discovering new facts and processes. Who is to do this work and for what it is to be done are questions for future consideration. The weak point in the contention of some of the teachers who have discussed this question from the technical side is that they have laid so much stress upon pioneering work that they have given the impression that they are of opinion that all our existing processes are effete and that the factories might close their gates and scrap their plant until the pioneer discoverer comes to their rescue. That, it is needless to say, is not the state of affairs. It must be realised that the results of pioneering research will fall upon barren ground unless the discoverer is supported by the highest technological competence. The development of that technological competency is within the province of education in precisely the same way as does the training of the research faculty. Pioneering research is wanted, but the results of his work must be added to our existing resources. The manufacturers on the other hand have not given sufficient weight to pioneering research; they only realise that this kind of work is telling against them when they find that their facts and processes are being supplanted. Looking at the actual state of affairs quite impartially from both points of view, it is quite clear to me that the weakness of this country in chemical industry is not so much due to our being unable to compete with other countries in the products which we do make, as to the lack of new products which we do not make. While such research work as we have been carrying on in our factories has been too narrowly concentrated upon the current processes, our competitors have been introducing new facts and processes which have developed into new lines of industry.

A general survey of the progress of chemical industry made during the last half century makes it evident that the expansion and development which have been a marked feature of that progress have been mainly due not so much to the tinkering of old processes, as to the industrial realisation of new scientific discoveries. Products which formerly were in demand have been replaced by newer products which are cheaper or which possess superior qualities for their particular purposes. Compounds which were discovered in the laboratory as the result of purely scientific investigation, having been found to be of industrial value, have been converted

from laboratory curiosities into marketable commodities. While current processes have been kept going at the highest efficiency which science and technology could command so long as they supplied products which were in demand, the factory doors have been always open for the admission of new processes. Moreover, the creation of new branches of manufacture has reacted advantageously upon the older branches by bringing about improvements in the latter and by creating an increased demand for the older products. I need only remind you how the development of the organic chemical industries has given an enormous impetus to the manufacture of "heavy chemicals" and inorganic products generally. It is of course unnecessary to mention specific cases before this Society, but in so far as this very practical outcome of the interdependence of science and industry is bound up with the question of the education of those who are to carry on our chemical industries in the future, it is of the greatest importance that the views of the teachers and manufacturers should be confronted.

Speaking as a teacher with some experience of manufacture, I may safely assert that as chemical industry has developed in the past so will it develop in the future, and we owe to that factory which closes its gates to the progress of scientific discovery. It is for this reason that we have for so long been preaching the doctrine of salvation by research. It is for the same reason that we attach so much importance to the educational value of research as a part of the advanced training of the works chemist. The whole question of the status of research in educational establishments in general and in technical institutions in particular would have been promoted if the chemical manufacturers had declared themselves in favour of this policy at the outset. If they will do so now it will help the cause both directly and indirectly. If the committees and governing bodies are made to realise that chemical industry requires technical chemists in the sense which I have endeavoured to define, it will help to counteract that deadening craze for turning out large numbers of book-trained youths which is sapping the vitality of the teaching staffs and producing no appreciable effect upon our industry. That which I have elsewhere defined as the "statistical fetish" together with what others have described as the "examination bogey" are unquestionably responsible for that estrangement between the manufacturers and the teaching institutions which is so frequently alluded to. One of the reasons why the teaching institutions have not been brought into more intimate association with the chemical manufacturers is because the staffs are given such scanty opportunities for developing themselves by the prosecution of research in connection with chemical industry either in general or in particular. The practical result is that the members of these staffs have not secured the confidence of the manufacturers. If there were a larger number of true experts and a smaller number of pure pedagogues in the technical institutions, these would be enabled to discharge with much greater efficiency that function for the performance of which they were nominally created. Since no teacher can become an expert in any particular domain of chemistry unless he is actively engaged in research, and since, under existing conditions, specialisation is rendered difficult if not altogether impossible, the manufacturer in difficulties or the would-be investor in a new undertaking turns for assistance to the private practitioner and rarely or never to the staff of the technical institution, which more often than not is technical only in name. I am thus brought once again face to face with the question of research in the technical institutions, and on this point I have been making further inquiries with the result that the conclusions arrived at two years ago with respect to pure chemistry are, I now find, equally applicable to applied chemistry. The assertion that there is a large amount of technical chemical research going on in these institutions the results of which, although not published, contribute to the advancement of chemical industry is, I regret to say, not borne out by facts. I have come to the conclusion that the institutions in question taken as a whole are not carrying on industrial chemical research. Three or four out of some 130 existing institutions might

be named in which some of the minor trade problems in the tinctorial and leather industries are made the subject of research by the staff and advanced students. In these cases, and to this extent, the industry is no doubt benefited, but the institutions which I have in mind are exceptional in being situated in the centres of the respective industries.* Nothing would give me greater pleasure than to find that this conclusion is erroneous, but as the evidence stands it cannot be maintained that, outside the province of the particular industries named, the chemical manufacturers of this country entrust any serious industrial research to the technical institutions. To prevent misunderstanding, let me add that the want of co-operation between the manufacturers and teachers is not altogether attributable to the lack of expert knowledge on the part of the latter. In some cases—I fear not many—these institutions have secured the services of experts in certain subjects, but, as a rule, the routine duties of general teaching and administration weigh so heavily as to give no opportunities for research of any kind. Indeed in some institutions research is discouraged or actually prohibited. It is of the greatest importance in the present state of the technical education question that the representatives of chemical industry should know the actual state of affairs, for no improvement is likely to be effected unless pressure is brought to bear from without. If the chemical departments of the various teaching institutions are to do for chemical industry that which their engineering departments are doing for mechanical industry there must be active co-operation between teachers and manufacturers.

Our available Educational Resources; Technical Institutions and Universities.

The general scheme of training which has been broadly outlined in this address embodies the views of all teachers who have had occasion to consider the momentous question of the education of the works chemist. I do not pretend that there would be complete harmony of view with respect to details of subjects or of time, but on the general lines laid down there would be no difficulty in elaborating workable curricula adapted to the requirements of teaching institutions in various centres. In dealing with the subject I have up to this point intentionally avoided drawing distinctions between the different types of educational establishments. The Universities have been alluded to incidentally, but it is mainly those newer institutions which have been called into existence by the demand for technical education which have so far been under consideration. And now, in concluding, it is necessary to particularise more definitely because, if there is to be any further *rapprochement* between the teachers and the manufacturers, it is essential that the actual state of affairs should be clearly indicated both with respect to our educational resources and to the attempts which are being made to meet the requirements of chemical industry. There are, as you are no doubt aware, a large number of Technical Schools of various grades in existence. I made a list two or three years ago and found that the technical education movement had been responsible for the creation of about 130 such institutions in different parts of the country. In nearly all these schools chemistry in some form or another is a recognised subject. Now it will appear of the nature of an anti-climax to the preceding portions of this address when I state that there is practically no Technical School in this country which provides a complete and co-ordinated course of training such as I have advocated. In a few of the institutions a three years' preparatory course for day students is carried on, but the advanced work, research or technological, is not provided for. In a few institutions in centres of particular industries, specialised teaching in

the technology of these industries is carried on, but these cases are quite exceptional, and it is doubtful whether such institutions the specialisation is not forced prematurely—whether, in fact, the students are allowed to enter upon their technological work with inadequate scientific preparation. The situation may be summed up by stating that for chemical industry technical education movement has been arrested just at that stage where the true technical training should begin.

In presenting for your consideration the actual state of affairs it must be clearly understood that I do not attribute the whole blame, nor indeed the greater part of it, to technical institutions themselves. They have not been encouraged to undergo development in the direct way required either by internal or external influences. They are in the first place the imperfections of elementary and secondary scientific education, and the difficulty of making those responsible for sending students into our chemical departments realise that full time must be allowed for training. In the next place the manufacturers must fairly recognise that it is only the voice of that industry which is immediately concerned that can, as it were, speak with any authority. If they had more freely co-operated with the committees and governing bodies of these institutions and with their teaching staffs they would assuredly have been greater progress in the development of higher schools of chemical technology. If they had insisted upon the necessity for a full and complete course of training as an indispensable condition of competency, and had refused to employ men who could not produce evidence of such training they would have helped the cause of technical education in this country enormously. As things are, the greater part of the chemical instruction in the technical institutions is carried on in evening classes. I believe I am voicing the opinion of manufacturers generally when I state that this kind of training is practically valueless for the training of industrial chemists. The persistent condemnation of evening work as a means of educating the works chemist, for which attitude I have long been responsible, has led to some considerable amount of misunderstanding, and as I have frequently been called upon to justify my position, I will make use of the present opportunity for explaining more fully what it is that both manufacturers and teachers agree in condemning.

It is sufficiently evident from the recent discussions in the provinces, and from the observations which I have put together for your consideration now, that a working period of three years is necessary to get a student to the end even of a preparatory training. Now suppose the student works for six hours a day during five days in the week, he spends during the working session 30 hours per week in learning chemistry and the collateral subjects. If the evening department is open for three hours a night the total amount of time which he can spend is 15 hours per week, if he works every evening. Even at this liberal allowance of evening instruction, it would therefore take him six years to arrive at the same standard as the day student. But in practice the evening department is seldom open for more than two hours, and not many institutions in this department open every evening in the week; neither is the evening session so long, as a rule, as the day session. Moreover, the evening student comes to his work at the end of his day's labour, and in the worst possible condition for taking advantage of the instruction offered. It would, I think, be nearer the truth to state that it would take the evening student 12 years at least to complete his preparatory training. I imagine, therefore, that any serious effect upon chemical industry is likely to result from this system of education is simply ridiculous.

To prevent any possible misapprehension—whether the foregoing conclusion be accepted or not—let me further point out that the campaign against evening instruction directed solely against that system of which the underlying assumption is that a course of evening instruction can make the equivalent of a course of day instruction—an assumption fundamentally wrong in principle. I have nothing to say against the students who enter for these courses; on the contrary, their zeal and energy in sup-

* Technical Institutions for training and research in particular industries are so few as to be practically non-existent in this country. For the leather industry we have the Herold's Institute at Birmensley which, through the munificence of the Leather-sellers' Company, is about to be developed into a kind of technical high school for that industry. It is to institutions of this type that we naturally look for "industrial research" in their respective subjects.

menting a day's work by attendance at evening classes is worthy of all commendation. As a class they are often superior to the day students, because they come with the object of making the best of their opportunities, whereas the day student often enters the college simply because his father sends him there and not because he has any real liking for the subject. But it is no use disguising the facts, and it must be realised that by evening work alone the average youth starting in life with the object of becoming a chemical technologist can never hope to attain any position of importance.

On the other side of the question of the function of evening instruction for technical chemists there is something to be said. It has already been stated that under certain conditions this kind of work may become useful. Let me specify what these conditions are because here also there has been some want of discrimination. Where a technical institution has on its staff or where it secures the temporary services of some expert in a particular branch of applied chemistry, then special courses by such an expert can be made of real value as supplementary to the routine course of instruction going on during the day. More particularly is this kind of work useful in connection with local industries. It is perhaps hardly necessary to point out that the student attending such a special course should, as a *sine qua non*, be made to produce evidence that he has reached a sufficiently high level in his general scientific training to enable him to follow the course intelligently. There is also another direction in which evening instruction can be and is being carried on with some advantage to chemical industry, and for which credit must be given to the technical institutions. I refer to the scientific training of men already engaged in particular industries. In such cases it must be remembered that the man, generally a foreman or manager, is already skilled in the *technique* of his industry, but has probably entered the works as a lad and has worked his way up without having had any general scientific training. Now with such men—who are always most zealous workers—a year or two spent at evening classes is of real value, because it helps to give some scientific basis to their factory experience. This has always appeared to me a branch of the work of the technical institutions deserving of the fullest sympathy and support from the manufacturers. But although valuable under existing conditions it must be clearly understood that I regard this kind of instruction as a temporary makeshift. Reduced to its lowest terms it is really an admission that the technical education movement has not yet reached chemical industry, because there ought in fact to be no demand for this kind of instruction. The scientific foundation should have been laid *before the youth entered the works*. When such classes lie out it may be taken as an indication that the technical education movement has influenced the chemical factories.

And so, after giving full credit to the technical institutions for that which they are doing as well as indicating that which they are not doing, we find ourselves face to face with a very remarkable state of affairs. Out of some 130 institutions with the prefix "technical" or its equivalent ("polytechnic") only a very small fraction can claim to be doing anything of the nature of technological work so far as chemical industry is concerned. When, as frequently happens, a parent consults me about the higher education of his son in chemical technology, I am bound to tell him that there is no institution in this country which I could conscientiously recommend him to be sent to for a post-graduate course in that subject. It is really astonishing that after 30 years of technical education applied chemistry should be lagging behind all other branches of technology. It is not that we have been niggardly in our expenditure over technical education here; on the contrary, we have been most lavish, but our aim has been for quantity rather than quality. We have been frittering our resources in multiplying the institutions for the low-level grade of work to such an extent that we have been unable to develop the higher schools. Although London is not favourably situated as a centre with respect to our chemical industries, it is to be hoped that the Imperial College of Science and Technology will give a

lead in founding a high school of chemical technology worthy of this country.* Reference has already been made to the conversion of the Technical Schools into academic establishments for preparing students for University degrees. From our point of view that is a perversion of function. So far as concerns the general question of scientific education and the spread of scientific culture I have nothing to say against this work; only let it be clearly understood that it is a distinct departure from the original motive which prompted the technical education movement. That movement, as I have previously indicated, was initiated because the academic training given in our Universities had proved inadequate as a preparation for a career in applied science. The multiplication of institutions for carrying on academic work, for which provision already existed, instead of developing that technical education which was so badly provided for, seems, to put it mildly, a very wasteful procedure. It is to be hoped that the general scientific status of the nation is being raised by these increased facilities for passing examinations. I am bound to confess that I can see no distinct indication of such a result at present—we must look to the future to decide this point. But so far as our industry is concerned I am sure the chemical manufacturers will support me in the contention that this type of work may be practically ignored. If it is claimed that a course pursued for the purpose of obtaining, say, a B.Sc. degree, however and whenever gone through, is at least a good preparation for a technological career, it is to me very doubtful whether this position could be justified under our present examination system. And even if the adequacy of such training be admitted there still remains the question, where is the technological training to be given? This brings me to the consideration of the Universities as schools of applied science.

Not the least remarkable feature in the history of education in this country is the fact that while large numbers of institutions originally intended for instruction in applied science are carrying on purely scholastic courses, the Universities, originally academic institutions, are now developing schools of applied science. This state of affairs might be taken as an indication that the technical education movement had been a failure. In some subjects such a conclusion could not be justified; the Technical Institutions, or at any rate some of them, can hold their own against the Universities. But in chemical technology, where development has been arrested, there would, I fear, be much justification for this conclusion. It may be taken that the underlying principle which prompted the recent discussions on the subject of the University training of industrial chemists was the desire to supply that higher technological training which the Technical Institutions had failed to develop. The question has taken the definite form whether the Universities should create departments of applied chemistry. In dealing with this question the manufacturers should have much to say. I cannot of course pretend to be the mouthpiece of chemical industry, but such views as have occurred to me in thinking over the matter for many years may be found of use, if not constructively, at any rate as a small step towards the practical solution of the problem.

In the first place in fairness to the Technical Institutions there must be discrimination between Universities. If a University has failed to create an active centre of chemical research its claim to usurp the functions of the Technical School is not a particularly strong one. On the other hand if a University has a reputation as a school of chemistry and the Technical Institution has no school either of research or technology, the case for the University is overwhelming. It must be remembered that the

* Since the above was written there has appeared a paper by Dr. Robert Pohl which was read before the Association of Teachers in Technical Institutions in Huddersfield ("Nature," April 15th, 1909, p. 205), which brings out some of the points dealt with in this address and which is well worthy of consideration. It appears from the author's statements that in this country we are spending in technical education about twice as much per head of population as Prussia, with educational results which "will not bear any comparison." Dr. Pohl gives great weight to the work of evening classes, but I gather from the context that he has under consideration such students as have been referred to above and to the technical education for mechanical and allied industries and special trades.

scientific staff of the Universities would be fully qualified to organise a preparatory curriculum. If the ordinary graduate courses were not suitable for the requirements of the chemical technologist they could, without much difficulty, be adapted. All that a University need do to form a school of chemical technology is to make provision for that kind of advanced work which has already been advocated in this address. Whether special chairs of applied chemistry should be founded seems to me to be after all a minor point. The answer to this question would depend very much upon the constitution of the existing staff and the nature of the local industries. The pure chemical instruction would of course, be under the control of the existing professoriate; if any member of the staff had any technological experience he might be made responsible for the general organisation of the department of applied chemistry and he might be given any suitable rank on the teaching body. The building and equipment of the technological laboratory would necessitate the expenditure of much money, but no more than the requirements of this much neglected side of the education of the industrial chemist seem to demand. There is no occasion to be extravagant nor to go beyond those generalised appliances in the way of plant or machinery to which I have previously alluded. There is no reason why the technological laboratory should not supply some of the materials required by the chemical department for general purposes or for special research. Speaking from experience, I have always found that students take particular interest in making products which are actually going to be used. The technological laboratory instructor must, as I have previously said, be a man of as wide a factory experience as possible. Such men should not be difficult to find; I could name many foremen in chemical works with whom I have come into contact who would have made excellent practical instructors in a technological laboratory. The professor, lecturer, or instructor in chemical engineering would, as already stated, be the chief difficulty at first: in fact, I am inclined to believe that any University founding a department of applied chemistry would have to look abroad for a thoroughly competent representative of this subject. But this point has already been dealt with to a sufficient extent, and it is only necessary to add that if the recent discussions should lead to any serious action being taken by our Universities it is to be hoped that the representatives of the local industries will be given a voice in framing the educational policy.

And now if I am asked more specifically whether the Universities should undertake this kind of work I have only to say that our need for it is great; so far as chemical industry in the abstract is concerned it does not matter who does it so long as it is efficiently done; it is a question of ways and means; who can do it best in the interests of our industry? The question cannot be answered in general terms because it is essentially a local question. The degree and direction of specialisation, if specialisation is admitted, would be to some extent influenced by local requirements, but the question of specialisation is really a distinct one, and requires separate consideration. In principle this question has already been answered, since several of the newer Universities have developed special departments for such subjects as fuel and metallurgy, fermentation, tinctorial chemistry, the leather industries, &c. No question need have been raised on this aspect of the technical education question since it is already an accomplished fact. If the question takes the form whether further developments in the way of special departments of applied chemistry are needed, I should say not, unless the subject is a wide one, such as fuel and metallurgy, which applies to many industries, or like electro-chemical industry, in which we are educationally weak. But the whole question of the desirability of a University undertaking special technological instruction in our subjects is at basis a personal one—it depends primarily upon the man and not upon the buildings or the equipment or even the locality. If we, as a Society, were asked, for example, to nominate professors for the heads of departments of a college of chemical technology, I think we could furnish a body of experts who would create a school of European fame. But these are the kind

of men whose services are in this country but very seldom added to our educational resources. We lose this great national developmental force, because no sufficient inducement is offered to the expert technologist to become an educator. Unless a University can command the services of such experts it would, I think, be wise to abandon all attempts to develop the teaching of applied chemistry in the special sense. It is most emphatically a case of catching your teacher first and letting him build up his school around him. When therefore I advocate the increase in our facilities, or rather the creation of means, for giving systematic instruction in chemical technology, I have always had in mind the generalised and not the specialised course. The latter is necessarily of restricted use as it appeals entirely to those whose careers in a particular industry are already marked out. This is only the case with a small minority of our technical chemical students; the majority want a general and not a special preparation, and at present they are so badly provided for in this country that they have to go abroad or to plunge at once into factory work with inadequate training.

It is evident that there is a serious gap in the education of the technical chemist which requires bridging over. If the Universities will supply this deficiency it will be a distinct gain to chemical industry in the future. I do not wish to imply that there is scope for an indefinite number of schools of chemical technology nor that every one of the newer Universities should develop such a school. Those in centres of chemical industry would obviously be the most appropriate for such work. If the University should already possess a department of special technology so much the better; general and special technology would be found mutually helpful. In advocating this much needed development of technical chemical education it must be understood also that I am now associating it with the Universities, because the recent ventilation of the subject has come from that side, and further because the technical institutions as a whole have made such an insignificant movement in the direction required. Reviewing the position quite impartially it must be obvious that it is to these institutions that we should have naturally looked for the necessary development. As matters stand, and in accordance with the general policy of "muddling through" which characterises our procedure, there has been a complete *bouleversement*! From the rational course of laying the ground work of pure science in the University, and building up the technological superstructure in the Technical Institution, we have departed to the irrational course of attempting the scientific foundation in the Technical School, and of appealing to the University to supply the technology. I may once more emphasize the fact that institutions founded originally for academic work have developed departments of special chemical technology, and institutions founded for the purpose of advancing industry are running classes in order to qualify for academic degrees. Truly an astonishing chapter in the history of education in this country when it comes to be written!

The practical outcome of these considerations must be to plead that a last chance may be given to the Technical Institutions, for we have evidently arrived at a crisis in their history in connection with the training of industrial chemists. If the higher work is to be taken over by the Universities it seems to me that the *raison d'être* of the Technical School will, for chemical industry, become a thing of the past. Most deplorable and most wasteful will it be if we find in the same town the University and the Technical Institution becoming rivals instead of colleagues. Of course the rational solution of the difficulty is that the Technical Institution should become a school of the University, as is the case at Manchester. But this solution carries with it the implication that the Technical Institution will raise the level of its technological teaching to the University standard. So far as I am concerned—I think I may say so far as chemical industry is concerned—that is precisely what we want. If these institutions will develop schools of chemical technology which University graduates could enter for their technological training, we shall have done something towards meeting the criticism of a recent French writer who, in reviewing the subject of

technical chemical education in the Universities of this country, sums up with the following statement:—

"En résumé, rien dans les écoles ne peut intéresser notre enseignement supérieur, toutes ont un but nettement professionnel; l'Angleterre ne nous fournit vraiment aucune méthode à préconiser; tant que l'industrie et la Science ne seront pas chez elle étroitement unies, les écoles techniques produiront bien d'excellents praticiens, mais l'Université ne fournira jamais les chercheurs, capable d'appliquer pratiquement les découvertes du laboratoire."*

The excuse that must be offered for the inordinate length of this address is the importance of the subject at the present time, when, under the new Patent Act, we are likely to see important developments in British chemical industry. So far the discussions on the advantages which we are supposed to derive from the establishment in this country of factories owned by foreigners seems, curiously enough, to have been concentrated exclusively upon the labour aspect of the question. Speaking on behalf of the teaching profession I can assure the manufacturers that we have at heart the very laudable desire of giving the British chemist as well as the British workman at least a chance. It is sufficiently evident from the general considerations which have now been submitted that the home-made chemist is at present very heavily handicapped at the outset of his career; the time is certainly ripe for considering the question of the training of the industrial chemist very seriously. There are many other points which I should like to have discussed—such as the attempts which have recently been made to bring the manufacturer into more intimate association with the teaching centres—but these must for the present remain in abeyance. The main issues before the educational and industrial worlds is the function of the University and of the Technical Institution respectively in the scheme of technical education. I lay claim to have done no more than attempt to smooth out this very tangled problem so that it may be handled in the future with a clearer conception of its true nature and a keener appreciation of the points awaiting definite decision. I venture to think that in framing any educational policy of real *i.e.*, practical, value for our subject, the Society of Chemical Industry can play a very important part. All the teachers of note, both in the Universities and in the Technical Schools are members; so also are all the leading chemical manufacturers of this and of some other countries. We are, in fact, both imperial and international. We have the means of bringing together a body of expert knowledge and experience, both educational and technological, such as is possessed by no other organisation. Surely it is our duty to promote chemical industry by taking an active part in the education of the technical chemist of the future. I am not advocating the conversion of the Society into a teaching body, neither am I calling upon our members to become stipendiary lecturers. There are other and more practical ways in which we can help the cause. It must be for my successors in this chair to bring these suggestions to a practical issue if they are thought worthy of it. An Advisory or Consultative Education Committee or Board, formed by our Council, and from the ranks of our members, comprising both teachers and manufacturers, ought to be of such power that no departure in the technical training of chemists in any educational establishment, whatever rank, could afford to neglect its counsels. In this, among other ways, the voice of chemical industry would make itself heard most effectively. The mere bringing together of such a Committee or Board would be of incalculable value to both the teachers and manufacturers composing it. If, carried away by the enthusiasm of the idea, I allow myself to foresee developments of national importance arising from such co-operation between the Society and the educational centres, I must add the extenuating circumstance that this is my last chance of propagandism from the Presidential platform. The work of such a Committee could, through our various sections, be extended all over the country, and the educational establishments thus brought into more direct

association with their nearest local Sections. Moreover, being as we are an American as well as a British and Colonial Society, we have the incalculable advantage of being able to secure the co-operation of those who have educational experience in other countries and under different industrial conditions. I do not think this suggestion is too Utopian to be realised practically; it would perhaps be premature to formulate it more definitely at this stage, but I confidently leave it for the future consideration of our Council and Officers.

In vacating the chair, which by your courtesy I have had the honour of occupying since the last Annual Meeting, I feel it something more than a mere formal duty to acknowledge the loyal support and active co-operation which I have on all occasions received from the Officers and Council. One pleasant memory which will be always associated with my tenure of office is that we have for the third time in our history been fortunate enough to secure as President an American colleague. By the election of Dr. Ira Remsen not only do we add one more link to that chain which binds us by sympathy of thought, language, and occupation to chemists across the Atlantic, but we have also the satisfaction of feeling that the chair is filled by a man whose works, both scientific and educational, are not only familiar to chemists and educationists in all English-speaking countries, but wherever chemical science and chemical industry are being developed.

Dr. W. H. NICHOLS said that, in the unavoidable absence of President Ira Remsen, the pleasant duty had fallen upon him of moving a vote of thanks to the President for his address. It would be quite impossible to refer at length to what the President said, but it had been his good fortune to read the complete address, and they could have no adequate idea of the argument from the portions which they had heard. Before attacking any proposition which had been put forward they should read every word of the paper, and he was quite sure they would find it worth their time and attention. The subject was one of very great moment, and it seemed extraordinary that anyone could doubt its importance. It was certainly important that the technological chemist should be educated for his work, considering that the future life of the world might be shortened enormously if the chemist did not come to the assistance of those who were so rapidly taking from the bosom of the earth her wealth of metals and materials. Why had there been a failure—if there had been—in arriving at a consensus of opinion as to the education of the chemical technologist? Possibly as great a reason as any had been the selfishness of the chemical manufacturers, who, hugging to their breasts what they believed to be secrets of great personal value, had been unwilling to give them to the world. He had always found that the teacher was ready to do his work, but how could a teacher in a technical school keep up to date on a subject which was hidden from him in the recesses and the privacies of a chemical plant? This was not true of education in any other form. In engineering, whether mechanical or civil, the engineer had simply to walk out into the streets of London, or any other great city, and see splendid evidences of the newest work, which might be his for the assimilation; but it was not so with the work of a manufacturing chemist. Speaking as one of that class he might say that, if they did not open themselves more, so that the very newest and latest things could be universally known, very possibly the education of the future chemist might be delayed too long. After all, research, whether simple research in the abstract, or in the field of chemical technology, was absolutely essential. If they looked back to the time fifty years ago, when those magnificent words were uttered by Dr. Playfair, how much light had their utterer at that time? How much more light had they to-day? Almost infinitely more, but what did anyone in that room know of the science of chemistry? One hundred years from now their descendants would still be in their infancy in this respect. How were they going to progress unless they gave the time, the energy, and the necessary work for opening up the field of research? That was where the gain was to be made. The application of research afterwards was a matter of detail. It might be done better

* "L'Enseignement technique de la Chimie dans les Universités," by M. Paul Baud, in the "Revue Scientifique," Feb. 1908.

by one, and worse by another, but knowledge to be gained by research was the one great necessity, and they could not do without co-operation. He hoped this address would be the beginning of an appeal which would result in much closer co-operation between the manufacturer and the teacher. He had great pleasure in moving a vote of thanks to the President for his able address.

Prof. W. A. TILDEN said he was very glad to have the privilege of seconding this resolution. It was not the first time the chemical world had been indebted to Professor Meldola for a clear exposition of this most complicated and difficult question. It was evident from his address that the question of technical education in chemistry bristled with difficulties of every kind; but however much room there might be for differences of opinion on many points of detail, they would all feel very grateful to him for his clear and careful statement of the case. Time did not allow of discussing even one of the subjects he had referred to, but he had been very glad to hear Dr. Nichols' remarks. He felt when he heard an eminent chemical manufacturer speaking to his colleagues and business associates and friends in such language, that there was some little hope for chemical industry. One point became very clear not only from the address, but from what Dr. Nichols had said. He had been convinced for many years that a large part of this question was entirely one for manufacturers themselves. It mattered not how a College was equipped with apparatus or machinery, or what kind of teachers were invited to take part in the instruction, it was quite impossible to give a complete technical course so as to turn out a man at the end of a certain number of years qualified at once to take charge of a branch of chemical industry. That arose not only from the fact that some teachers really did not know anything about the industrial aspects of the subjects they had to teach, but from the practical difficulty which was constantly being forced upon him as a teacher by having to discuss with his students what they were to do. At the end of three or four years, when a man had completed his ordinary academic course, and was a fairly good mathematician, physicist, and chemist, with a certain amount of skill, he had then to ask himself what line was he to take; should he devote a year or two to further laboratory study, to the problems connected with say heavy chemicals, such as sulphuric acid or soda? He might have wasted the whole of his time if he had not the opportunity of finding his way into that department of the industry; and when the opportunity came he might find he was called upon to assist in manufacturing colours or alkaloids, or something of a totally different kind. The solution of this difficulty lay with the manufacturers. Until they were prepared to take the academically prepared student, a man who had been instructed in the methods of research, and had a fair amount of intelligence, and put him into a place in their works, and instructed him in his business, he did not see how they were to get any further. There was a disposition nowadays to require of the young man taken into industrial chemistry rather too great diversity of accomplishments. It was not necessary only that he should be a skilled and experienced chemist, that he should know something about electricity, that he should have sufficient mathematics at command to enable him to tackle any problem in physical chemistry, and also that he should know something of engineering, but he had to study the nature of markets, and how to deal with matters of business. It seemed to him that there could not be rolled into one person a research chemist, a works manager, and a business manager; it was physically and humanly impossible that any such person could ever be found, and the man who was to assist as a scientific chemist in a works must be allowed to devote himself to that department of the business. If he were wanted in the office that was one thing, but the laboratory was another. It was not fair, and neither human strength, nor human life, were sufficient or long enough to enable a man to undertake all these various functions.

The motion was put by Dr. Nichols, and carried unanimously.

The President, in responding, thanked Dr. Nichols and Professor Tilden for the kind way in which they had

proposed and seconded this motion, and he would take the opportunity of announcing the result of the ballot.

Report of Scrutators.

The Scrutators beg to report that they have examined 272 ballot lists, of which 10 were spoilt, and declare that the following are elected Ordinary Members of Council:—Mr. D. Lloyd Howard, Prof. W. R. Lang, Mr. B. E. R. Newlands, and Dr. Julius Raschen.

Prof. Ira Remsen has been elected President, and Dr. Geo. Beilby, Mr. E. Grant Hooper, Prof. R. Meldola, and Dr. R. Messel have been elected Vice-Presidents.

The appointments by the Council of Mr. Thomas Tyrer and Dr. Ludwig Mond as Hon. Treasurer and Hon. Foreign Secretary are approved; and Messrs. Norton, Feasey, and Slade are elected Auditors.

(Signed) ERNEST LINDER, C. D. McCOURT.

The new Council is therefore composed as follows:—

LIST OF COUNCIL, 1909-1910.

President: President Ira Remsen.

Vice-Presidents:

Dr. G. Beilby, F.R.S.	Dr. R. Messel.
Eustace Carey.	Sir Boverton Redwood.
Dr. J. T. Dunn.	Walter F. Reid.
E. Grant Hooper.	Geo. C. Stone.
A. R. Ling.	Dr. T. B. Wagner.
Prof. R. Meldola, F.R.S.	R. C. Woodcock.

Ordinary Members of Council:

Prof. P. Phillips Bedson.	D. Lloyd Howard.
Prof. W. Hodgson Ellis.	Dr. Charles A. Keane
Oscar Guttmann.	Prof. W. R. Lang.
H. Hemingway.	B. E. R. Newlands.
Prof. G. G. Henderson.	Dr. Julius Raschen.
Prof. W. R. E. Hodgkinson.	Harold Van der Linde.

Sectional Chairmen and Secretaries:

Dr. T. Slater Price.	BIRMINGHAM.	F. R. O'Shaughnessy
Dr. Milton L. Hersey.	CANADIAN.	Alfred Burton.
Max Muspratt.	LIVERPOOL.	W. Roscoe Hardwick.
Dr. J. Lewkowitsch.	LONDON.	Julian L. Baker.
R. H. Clayton.	MANCHESTER.	Julius Hübner.
C. J. Potter.	NEWCASTLE.	Dr. F. C. Garrett.
Dr. W. H. Walker.	NEW ENGLAND.	Alan A. Claffin.
Maximilian Toch.	NEW YORK.	Dr. H. Schwellzer.
S. J. Pentecost.	NOTTINGHAM.	S. R. Trotman.
D. J. Playfair.	SCOTTISH.	Dr. G. B. Neave.
Prof. J. A. Schofield.	SYDNEY, N.S.W.	T. U. Walton.
Prof. W. M. Gardner.	YORKSHIRE.	Thomas Fairley.

Honorary Treasurer: Thomas Tyrer.

Honorary Foreign Secretary: Dr. Ludwig Mond, F.R.S.

General Secretary: Charles G. Cresswell.

Dr. H. SCHWEITZER moved the adoption of the following Draft Regulations made under the provisions of By-law 38:—

MEMBERS.

1. At whatever period of the year a new Member may be elected he shall be required, unless the Council shall determine otherwise, to pay his subscription for that year; having done which he shall be entitled to receive all the numbers of the Society's Journal for that year. (c.f. By-law 7.)

2. If a Member who has been duly elected, and has paid an Entrance Fee and one or more subscriptions, resigns under By-law 14, and later seeks re-election, the Council may re-admit him without further Entrance Fee.

ANNUAL GENERAL MEETING.

3. When a ballot is required under By-law 26, then at such stage in the proceedings of the Annual General Meeting as shall be most convenient, the Members present shall hand their Ballot Lists to the General Secretary, or, in his absence, to such other person as the President may appoint. Members unable to attend the Meeting may send their Ballot Lists before the Meeting to the

General Secretary in sealed envelopes. Each such sealed envelope must be marked "BALLOT LIST," and must, moreover, have written upon it the name of the Member sending it. The names written upon such sealed envelope having been compared with the Society's Register by the General Secretary, such sealed envelopes shall be opened at the Meeting by Scrutators appointed by the Meeting. The Scrutators shall see that the conditions of the Ballot are strictly fulfilled. Any Member shall be at liberty to strike out any name or names of Ordinary Members of Council printed on his voting paper.

COMMITTEES.

4. No Special Committee, nor any Committee of a Local Section shall have any control over the funds of the Society, except to the extent to which funds for its use may be voted by the Council. An account of the manner in which any funds so voted for the use of any Committee have been expended shall be furnished to the Council on or before the 15th of November in each year.

LOCAL SECTIONS.

5. All elections to the Committee of a Local Section and all elections of Officers of the Section, with the exception of those to fill up unforeseen vacancies, shall take place so that they can be reported to the Council in time to be considered at the Meeting held under By-law 24 not less than two months prior to the Annual General Meeting; but the Members of Committee and Officers thus elected shall not take office and those whom they are to succeed shall not retire from office until the close of the Annual General Meeting aforesaid.

Mr. T. FAIRLEY seconded the motion, which was carried unanimously.

Place of Annual Meeting in 1910.

Mr. D. J. PLAYFAIR (Chairman of the Scottish Section) said he had much pleasure on behalf of the Scottish Section in inviting the Society to hold the next Annual Meeting in Scotland, with its headquarters in Glasgow. On two previous occasions, namely, in 1898 and 1901, Glasgow had been honoured by the Society meeting there, so that the town was not unknown to most of the members. Those two visits synchronised with an International Exhibition which was being held there, but next year they could not hold out the prospect of a similar attraction; still it might be hoped that Glasgow and its neighbourhood was sufficiently interesting to make them worthy of a visit. They had very considerable and diversified industries, including some chemical works, within their borders, and some fairly picturesque scenery within easy reach, and in the nine years which would have elapsed since the Society last visited Glasgow there had been a continual industrial advance in many directions. Amongst educational institutions there had been a great development, especially in the Technical College, which would be of special interest to the members in view of the address they had heard that morning. If the invitation were accepted he was quite confident that the members of the Scottish Section would give the Society a most hearty welcome, and do all they could to make the Meeting a success.

Prof. G. G. HENDERSON, in seconding the motion, said that everybody north of the Tweed would receive them with great cordiality.

The motion having been carried unanimously,

The PRESIDENT said he would ask their colleagues from the other side of the Tweed to convey the best thanks of the Society for this invitation, which was cordially accepted.

Mr. MAXIMILIAN TOCH (Chairman of the New York Section) then proposed a vote of thanks to the University of London and the Organising Committee of the International Congress of Applied Chemistry, for granting the use of that Hall for the Annual Meeting.

Dr. T. E. THORPE, in seconding the motion, said he did so with all the more pleasure that he understood that the University had not in any way depleted the funds of the Society in return for its hospitality, and whilst he congratulated the Society on this fact, he congratulated

the University much more on the manner in which it had seized the opportunity of showing what it ought to show as a University.

The motion was carried unanimously.

The PRESIDENT, in concluding the Meeting read a letter from Prof. Ira Remsen, the newly elected President.

Mr. THOMAS TYLER suggested that a message should be sent to President Remsen telling him he had been unanimously elected, and congratulating him on behalf of the Meeting.

This was agreed to, and the proceedings terminated.

LUNCHEON.

At the conclusion of the proceedings the members were entertained at luncheon by the London Section in the Great Hall of the University of London, the chair being taken by Dr. Lewkowitsch. Many foreign members and visitors were present.

After the usual loyal toasts had been given,

The CHAIRMAN proposed the health of the guests. He said the London Section of the Society felt proud to welcome their distinguished and illustrious guests, among whom were the most representative men of science from the four corners of the world. After referring in detail to the names of a great number of the distinguished visitors present from Japan, China, Canada, the United States, France, Germany, Italy, Austria, and the Colonies, and then to Principal Miers and Rector Dr. Bovey, he pointed out that many of those he had named were members of the Society. Amongst them were Sir Henry Roscoe, and a large succession of past Presidents. He referred also to their President, Professor Meldola, as the true type of what a member of the Society should be, a technical man who combined the highest flights of science with technical success. He, like Faraday, might have added fortune to fame if he had kept to industry, but, like Faraday, he threw in his lot with science. They were proud to see before them the representatives of every Section of the Society. They hoped before long to have other Sections in the southern hemisphere, including one in New Zealand, where the cold storage industries were so much coming to the front. Some day they also hoped to have Sections in South Africa and in India, and to increase the number in Canada, and also in the United States. The bond which kept them together was the Journal, as all their members wanted to get value for their money, and were very much alive to the needs of the day. They might not have discarded classical knowledge, but at any rate they had altered the old Latin adage, *multum non multa*, into *multum et multa*. In connection with the Journal, much voluntary work was done by experts, and it was looked after in a manner in which no other Journal in the world was. If imitation was the sincerest form of flattery they might flatter themselves they had that admiration, for their German friends had published a Journal not very different from their own, and he congratulated them on their success, and was proud to think that in following English methods they were doing equally well. Their American friends were also publishing a Journal of applied chemistry and chemical engineering, and were going to make a friendly effort to do better. In conclusion he offered a hearty welcome to the ladies present. He complied with the toast the names of Professor Albin Haller, Geh.-Reg. Rath Dr. von Böttinger, Prof. Comm. Arnaldo Piutti, and Dr. F. W. Clarke.

The toast having been received with great enthusiasm,

Professor HALLER said: "Je suis heureux de l'occasion qui m'est offerte pour vous dire en quelle haute estime nous tenons votre Société, tout ce que nous lui devons et toute la sympathie qu'elle nous inspire."

"Ecluse, il y aura bientôt trente ans, sous l'impulsion de l'illustre doyen de la chimie Britannique, notre confrère Sir Henry Roscoe, votre Société, si elle n'est pas la plus ancienne en date, a incontestablement pris la première place parmi toutes celles qui de par le monde, s'occupent des applications de la chimie à l'industrie."

"Et cette place elle l'occupe non pas uniquement par le nombre, près de 4,500, et par la qualité de ses

membres, mais encore et surtout par les signales services qu'elle a rendu, et rend tous les jours, à tous ceux qui s'intéressent aux questions de chimie industrielle.

"Votre organisation en douze sections réparties, non seulement sur tous les points du vaste empire, mais encore aux États Unis, à New York et à Boston, en fait une Société internationale, et répond bien au but que vous poursuivez, celui de susciter l'attention, la curiosité de tous vos adhérents et de provoquer ainsi les initiatives les plus fécondes et les plus hardies.

"En parcourant la liste de vos anciens Présidents et de vos Conférenciers on est frappé de voir le soin que vous avez toujours mis à maintenir une balance égale entre les théoriciens et les techniciens, pourvu qu'ils se fussent distingués par une œuvre marquante. Quant à votre Journal, il n'est à ma connaissance aucune publication, aucun organe au monde qui, sous une forme aussi claire, aussi concise et aussi méthodique, contienne sous les multiples rubriques autant de documents précieux et pour le chimiste, et pour le technicien, et pour le commerçant. Vous songez à tout ce qui peut être utile pour votre industrie, sans vous préoccuper dans votre libéralisme ardent et élevé, de savoir si, en divulguant le résultat de vos expériences et de vos observations, vous fournissez des armes à vos rivaux."

GEH. REG. RATH VON BÖTTINGER, MITGLIED DES HERRENHAUSES, in a very eloquent speech, delivered in German, referred to the coming Congress and to the many visitors who had arrived from all parts of the world. He laid stress on the fact that such international gatherings not only brought together representatives of chemistry, but also distinctly made for the peace of the world, in that they promoted the common brotherhood of man, and furthered the highest aims of humanity by clearing away such misunderstandings as would arise sometimes between nation and nation. He felt convinced that this would mark the most important feature of the Congress. Concluding in English, he recommended them to take to heart the famous lines from Longfellow's "Psalm of Life":—" . . . And, departing, leave behind us footprints on the sands of time ;

"Footprints, as perhaps another, sailing o'er life's ocean main,

"A forlorn and shipwrecked brother, seeing, shall take heart again."

"Prof. PIUTTI said: "Permettetemi, Signore e Signori, di brindare alla salute ed alla prosperità della Società dell' Industria Chimica Inglese, sotto i cui auspici ci troviamo qui riuniti e che ci accoglie con tanta ospitalità e cortesia. A che servirebbero mai le aride ricerche del laboratorio ed i trovati dei più insigni scienziati se non vi fosse chi li applica per il maggior benessere di tutti? Se un eletta d'uomini, uniti fra di loro da un ideale comune non sviluppasse intorno a sé e non portasse nei paese anche i più lontani i benefici delle conquiste scientifiche, ogni più elevato e fecondo pensiero umano resterebbe sterile.

"A questa Società dunque che realizza l'ultimo sogno di Fausto morente a nella viva e palpitante realtà di mille fabbriche afferma i suoi forti propositi, seguendo un gradino più alto nel progresso umano, io vi invito a bere, col più caldo sentimento ed ammirazione, col desiderio più intenso che nel luminoso cammino proceda con attività ognora crescente sino a raggiungere i suoi alti destini."

Professor F. W. CLARKE said that gathering might almost be defined as a sort of chemical experiment, consisting of a bright light, a loud noise, and a smell. They certainly had had most illuminating speeches, there had been a reasonable amount of loud noise, and in a gathering of chemists there would generally be found more good sense than in any other gathering whatever. There were forty or fifty members present from America who much enjoyed the present entertainment, and were anticipating other pleasant things to come. They wanted to retaliate, and were very anxious that three years hence the English members should visit America and see how well they had learnt the lesson which had been set here. America was a new country, with the enthusiasm of youth, but they had good teachers. Priestley spent the last ten years of his life in America,

and was buried there, so that they owed their first inspiration in chemical work to England; but they hoped that those on this side of the Atlantic would come over and see how far they had made progress, which at any rate they had tried to do. He would not attempt to say what they were doing in America for fear he might put himself under the imputation which his countrymen sometimes laboured under, of bragging, the reason being that they simply told the truth about their country and nothing else. At any rate he hoped that in three years' time they would have a large delegation from all the countries of Europe to America as missionaries to help them to do better than they had done before, and he could assure them that every European who came over would have as hearty a welcome there as those from America had had on this side of the water.

In the afternoon the London Section and Ladies' Committee gave an "At Home" in the Great Hall of the University of London, which was very well attended. During the day the "Red Band," under the direction of Mr. Alfred Batty, gave an excellent selection of music. A very successful photograph of the party at luncheon was taken by Messrs. Fradelle and Young, 283, Regent Street, W., from whom copies might be obtained, price 4s. 6d. each unmounted and 5s. 6d. mounted.

ENTERTAINMENT AT LONDON UNIVERSITY, MAY 29TH, 1909.

On Saturday evening, May 29th, the members of the Congress were entertained at the Imperial Institute Buildings by the London Section of the Society of Chemical Industry. Invitations were issued to 3500, and there was a very large attendance, the guests being received by the officers of the Section and their wives. The Great Hall, Marble Hall, East and West Galleries, and gardens of the University of London were all used. The principal part of the entertainment was the concert in the Great Hall, where the artists included Miss Myra Hess, Miss W. Smith, Miss M. Wadia, Miss Carmen Hill, Herr and Madame Tobler, Mr. Marcus Thompson, Mr. Harold Wilde, Mr. Charles Coborn, and Mr. John Bardsley. Some thought-reading experiments were carried out by Professor Anders. Mr. Cyril Towsey was the accompanist. In the Upper Galleries psychological character studies were given. There was dancing in the East Gallery, and the gardens, which were illuminated, were much used for promenades. The entertainment lasted from half-past eight o'clock until midnight.

INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY.

The seventh International Congress of Applied Chemistry, and the first to be held in London, was formally opened on Thursday, May 27th, at the Albert Hall, by the Prince of Wales, who was accompanied by the Princess of Wales. Their Royal Highnesses were escorted on to the platform by Sir Henry Roscoe, Hon. President, and Sir William Ramsay, Acting President, of the Congress. The Prince at once took the chair and opened the proceedings. On his left were the Princess of Wales, Dr. Harvey W. Wiley, chief representative of the United States, M. Armand Gautier, representing France, and Professor E. Paternò, representing Italy. On his right were Sir Henry Roscoe, Sir William Ramsay, Professor Dr. O. N. Witt, representing Germany, and Professor Arrhenius, representing Sweden. Among those present on the platform were the American, French, Italian, and Russian Ambassadors, the Chinese, Danish, Japanese, Netherlands, Portuguese, and Swedish Ministers, the Duke of Northumberland, Lords Rayleigh, Strathcona and Wolverhampton, Mr. Runciman, M.P., the Master of Elibank, M.P., Sir Hugh Bell, Bart., Sir Wm. Crookes, Sir Jas. Crichton-Browne, Sir John Brunner, Sir Richard Garton, Sir Walter Palmer, Sir Jas. Dewar, Sir Boverton Redwood, Sir H. Trumion Wood, Dr. G. T. Beilby, Prof. R. Meldola, Prof. W. A. Tilden, Dr. T. E. Thorpe, Dr. L. Mond, Prof. P. F. Frankland, Dr. J. Lewkowitch, Sir Andrew Noble, Prof. W. H. Perkin, Mr. John Gretton, M.P., Prof. Adrian Brown, Dr. J. A. Voelcker, Mr. N. H. Martin, Mr. T. Tyrer, and a throng of official delegates.

In opening the proceedings the PRINCE OF WALES said:—

Your Excellencies, my Lords, Ladies, and Gentlemen.—It gives me much pleasure as Vice-Patron to preside over the first meeting of this important International Congress of Applied Science, and the Princess of Wales is very glad to accompany me on this occasion. Delegates and members, including many ladies, have come not only from every country in Europe, but all parts of the world—literally from China to Peru. Six Congresses have already been held in the various capitals of Europe. This is the first time that you have assembled in London, and in the name of the King, who is patron of this Congress, I offer you his Majesty's most hearty welcome. His Majesty is very glad to think that the foreign representatives will be able to visit Windsor Castle during their stay in this country. The main object which you all have in view is to discuss in your numerous sections the many topics of interest and importance that are continually arising owing to the marvellous discoveries which the science of chemistry, both pure and applied, is making from day to day. Those interested in some special branch meet in the different sections their *confrères* from other lands to their mutual benefit. In the larger gatherings, which I am glad to see have been arranged by the committee, members will have further opportunity of social meeting. These conferences, whether of a scientific or of a more intimate character, between men living in distant lands, all working for the same object, although under different conditions, cannot but be favourable to the progress of science and of the industries to which many of you have devoted your lives, as well as to the general peace of the world. I fully appreciate the important part which chemistry plays in almost every branch of our modern industry. We all recognise that without a scientific foundation no permanent superstructure can be raised. Does not experience warn us that the rule of thumb is dead and that the rule of science has taken its place, that to-day we cannot be satisfied with the crude methods which were sufficient for our forefathers, and that those great industries which do not keep abreast of the advance of science must surely and rapidly decline? On behalf of the Princess of Wales and for myself, I offer our cordial greetings to the members of the Congress, and I earnestly trust that great results may accrue from your deliberations. I now have much pleasure in declaring the seventh International Congress of Applied Chemistry open.

SIR HENRY ROSCOE, the Honorary President, who was then called upon by his Royal Highness, said he rose in the first place to express on the part of British chemists a hearty English welcome to their *confrères* who had assembled from all parts of the world. He rose also to ask the members and delegates to express their thanks to the Prince and Princess of Wales. A formal vote of thanks was unnecessary, for the thanks came from all their hearts for the grand send-off which their Royal Highnesses had given the Congress and for the kind and felicitous terms in which the Prince had opened the proceedings.

SIR WILLIAM RAMSAY, the Acting President, said, following the lead of the Prince of Wales and of Sir Henry Roscoe, it fell to him to bid the delegates welcome to the Congress. The last meeting was held in Rome, where the King of Italy occupied the position which the Prince of Wales had kindly filled that day. There the Hon. President was the world-renowned Cannizzaro, the publication of whose views, almost exactly 50 years ago, effected a revolution in chemical thought, and made clear what was formerly obscure and involved. It was delightful to think that Professor Cannizzaro, though unable to take part personally in this Congress, was strong and well, and in full possession of all his faculties. Professor Paternò was then Acting President, and Sir William Ramsay took the opportunity of bidding him welcome to England. He also welcomed the small band of young Italians to whom the surplus of the funds collected for the sixth Congress had given an opportunity of visiting England. Professor Witt, the Acting President of the fifth Congress, which was held at Berlin, was also a guest. They thanked him for coming, and for the great help

he had given the Organising Committee by his advice. They were glad also to welcome M. Lindet, the President of the first French Congress. It was impossible to draw a hard-and-fast line between scientific and technical chemistry. Chemistry was above all a practical science, although in recent years it had tended to become more and more a branch of applied mathematics. The principles remained the same, and indeed the methods were only slightly varied, whether the apparatus used were beakers, test-tubes, funnels and flasks, or tanks, filter-presses, and autoclaves. The chief difference between the pure science and its application consisted in a satisfactory answer to the question—all-important to the technical chemist, but wholly irrelevant to the man of science—"Will it pay?" On the answer to that question the commercial success of a process depended; but in its essence, chemistry, whether scientific or industrial, was one. This, he thought, had hardly been realised in a practical manner on this side of the Channel, or, indeed, on the other side of the Atlantic. But our Continental friends had long seen and acted on the conviction that the industrial prosperity of a country could best be advanced by a close friendship and constant association between the technical and the practical workers, between the University and the factory, between the pure and the applied science. Congresses like the present could teach them much: if they learnt this lesson from them they would have gained a valuable national asset. It had often been said that science was cosmopolitan, and knew no country. The existence of such a Congress as that was in itself a proof of the truth of the saying. There were present representatives of every civilised State in the world, met together to discuss how best to develop the special branches of chemistry to which they devoted their lives: how to further their progress and to mark the level to which they had already attained. There was a city on the other side of the Atlantic whose motto was one of the noblest imaginable—"Philadelphia Maneto!"—"Let brotherly love continue!" Sir William Ramsay then addressed a few words of cordial welcome to the foreign delegates successively in French, German, and Italian.

Dr. H. W. WILEY, Department of Agriculture, Washington, acknowledged the welcome on behalf of the United States of America. He said there was no more apt illustration of the utility of chemistry than to say that were its principles unknown and unapplied the teeming millions of the globe would at this moment be unclad and starving. The great strides now making to apply the principles of prophylaxis in medical science were largely due to the services of chemistry. In fact sanitation was principally a chemical problem; pure food, pure air, pure water ensured pure activity of mind and body, and cured disease by evading it and prolonging by many years the most valuable part of human life—viz., its period of *maximum* endeavour. Chemistry had also undertaken to improve the morality of man. It detected frauds and adulterations in articles bought and sold. It exposed the manufacturer and dealer who made and sold articles deleterious to man or under a false name or representation to public scorn and to the penalties of the law.

Professor ARMAND GAUTIER returned thanks on behalf of the French delegates, and said that if in the past political causes had divided Great Britain and France, mutual appreciation of good qualities and frequent complementary aptitudes and a tradition of a common culture had gradually drawn them together more effectively than could have been done by formal treaties. In the development of industrial science England and France remained not the only, but the great, leading nations—always rivals, but never enemies. Incidentally Professor Gautier recalled the names and discoveries of a long series of eminent chemists of both nations, beginning with Priestley, Cavendish, Dalton, and Humphrey Davy, and showed that Englishmen and Frenchmen had again and again worked in the same fields.

Professor Dr. O. N. WITT, speaking in German, said that in the name of the Imperial German Government and the Prussian Royal Government, and also on behalf

of the German Chemical Society, whose president he had the honour to be, he expressed the warmest good wishes for the success of the Congress. He hoped it might not only equal its predecessors in the extent and importance of its labours, but might also mark a further advance in the path of international discussion and understanding trodden by their science. The field of applied chemistry covered by the Congress extended in two directions: it included the analysis by scientific methods and the control of commercial raw materials and finished products, and also the advance of the chemical industries concerned with them. There was no country which was not in some degree interested in the subjects of their Congress. These Congresses promoted friendly understanding and noble rivalry, and therefore they enjoyed the patronage of those who guide the destinies of nations. As a past President he begged their Royal Highnesses to accept the thanks of all taking part in the Congress and to convey them to his Majesty the King.

Professor E. PATERNO was next called upon. Speaking in Italian, he said that as President of the sixth Congress at which, held in the eternal city of Rome, London had been chosen as the seat of the present Congress, it was his duty to pronounce an inaugural greeting to that imposing gathering of illustrious scientists and practical and expert manufacturers. In the name of the Government of his Majesty the King of Italy, of the Royal Academy of the *Lincci*, and of the Italian Chemical Society, he offered the warmest wishes for the success of the Congress, and returned hearty thanks to the Organising Committee in London for their hospitable and genial reception. They were all bound to respond enthusiastically to an invitation from the country which gave to chemistry Boyle, Black, Cavendish, Priestley, Wollaston, Dalton, Davy, Faraday, and Graham. Even in the busy, noisy, bewildering rush of London life men of science yet knew how to find the tranquillity and quiet necessary for the investigation and discussion of the most abstruse problems of philosophy and science. He concluded by saying that Italians cherished another sentiment not less warm in the memory of the hospitality and succour found in this classical land of liberty by the fathers of their political regeneration.

Professor ARRHENIUS, Stockholm University, responded for the delegates of other foreign countries, and, describing England as the classical land of applied chemistry, said that it was in this country, and especially in London, that successful efforts had been made to improve hygiene by the application of chemical methods, and as a result London had the lowest death rate among large cities of the world.

The proceedings closed with the playing of the National Anthem on the organ.

JOINT BANQUET OF THE INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY AND THE SOCIETY OF CHEMICAL INDUSTRY.

On Friday evening, May 28th, 1909, the joint banquet of the International Congress of Applied Chemistry, and of the Society of Chemical Industry, took place at the Crystal Palace. Sir William Ramsay, K.C.B., F.R.S., occupied the chair, supported by Prof. R. Meldola, F.R.S., President of the Society of Chemical Industry. There were present between 1400 and 1500 members of the Congress, a very large proportion of whom were members of the Society of Chemical Industry.

The PRESIDENT gave the toasts of "The King," and "Foreign Rulers."

The PRESIDENT then proposed the toast of "Our Friends from Abroad." They had amongst them on that occasion representatives from no less than twenty countries, and it was obviously impossible to give each country the chance of responding for itself, especially as there was an exhibition of fireworks to follow the dinner. He should, therefore, single out a few countries, not because of their eminence, but in alphabetical order, and would call upon delegates from those countries to respond. He first called upon Dr. Nichols.

Dr. W. H. NICHOLS (New York) said he was very pleased to reply on behalf of America. As he spent his summers in Canada, resided in New York, and was a representative of the Mexican Government, he thought he was entitled to speak for North America. It was impossible to express their sense of the wonderful hospitality with which they had been greeted. They had had the honour of having the Congress opened by the Prince of Wales, and, if he might say it respectfully, after that he felt that they could call him one of themselves. But what could he say about those two magnificent men who had acted, and were still acting, as Presidents of the Congress, of the ladies who had shown them the most magnificent hospitality, and of all that had been done to make the Congress a success? The chemist owed much to the world, but the world owed much to the chemist, and it would owe more before it owed less. The President had asked for a few well chosen remarks. His mathematical education would enable him to comply with the first part of that request, but he regretted that the rest of his education rendered it impracticable for him to comply with the second. However, on behalf of the 4500 chemists whom he and his friends represented, he begged to return their most hearty thanks, and to assure them that in that great problem of the future just about to commence, the building up rather than the pulling down of the Universe, the chemists of America would do their share.

The PRESIDENT said he regretted the absence of the official representative of the Austro-Hungarian Empire, Prof. Strohmer, but he had great pleasure in calling upon his old friend Dr. Brauner to reply for Austria.

Prof. BOHUSLAV BRAUNER said he accepted the honour conferred on him in the name of all the nations forming the Austrian Imperial Monarchy represented at the Congress. He desired to thank their English colleagues for their hospitality and the kindness they had shown. He was not a stranger in this country, having studied 30 years ago under their honoured President, Sir Henry Roscoe, and he was thus able to appreciate the great progress made in England since that time both in pure and applied chemistry. Thirty years ago Sir Henry Roscoe had to preach a crusade against the domination of the "rule of thumb," and he rejoiced to find that the highest in the land now declared that the "rule of thumb" was dead, and the Congress of Applied Chemistry was the one to give it its *coup de grâce*.

Prof. ARMAND GAUTIER responded on behalf of France. Speaking in French, he pointed out that over 300 French chemists had come over to take part in the Congress and if the ladies were added, their number reached over 350. This was the best possible manner of demonstrating the *entente cordiale* which existed between the English and French chemists, an understanding which was more than a century old, dating back, as it did, to the time when Priestley came to Paris, when Lavoisier called William Black his master, and when Napoleon allowed Humphry Davy to travel in France with Faraday as his assistant at a time when every other Englishman was forbidden French soil.

Dr. VON BÖTTINGER, having responded in his own language for Germany, added in English a few words referring to the visit of the Prince and Princess of Wales to the Congress. Many of them had revived old friendships, and made new ones. He concluded by expressing the hope that one of the results of the Congress would be to advance, not only the work of science, but the work of furthering amiability and friendship amongst all nations.

Prof. Com. PIUTTI briefly responded for Italy.

Prof. HOOGWERFF (Holland), being called upon to respond for the Other Countries, said it was a great honour to respond for the guests of so many other nations, but the circumstances were not favourable to a lengthy speech. The science of chemistry owed very much to England. It was here that Faraday by his discoveries laid the foundation for the theory of ions, and it was

that and the discovery by the President of the rare gases of the atmosphere, and to the disintegration of what only a short time ago was considered to be indivisible, which had done so much for science. Equally important, if possible, was the share of England with regard to applied chemistry. Not far from there the industry connected with sulphuric acid had its birth, and English hands tended its growth. London was the first city lighted by coal gas, and a Scotchman named Young laid the foundation of the shale industry. He might also refer to the coal tar industry, and many others which had taken their birth in Great Britain. Having referred to the grand reception afforded the delegates by the Lord Mayor and the Corporation of London, and the reception at the Foreign Office, he concluded by proposing the health of Sir Henry and Lady Roscoe and Sir William and Lady Ramsay.

The PRESIDENT said there were still about 19 toasts on the list, which the Toastmaster would recite in order, and he would ask them to give a cheer for each, and three cheers for the British Empire at the conclusion.

The list was then read, beginning with Argentina, and ending with Turkey.

A display of fireworks in the grounds of the Palace brought the proceedings to a close.

On Saturday morning, May 29th, the King received a deputation from the International Congress of Applied Chemistry, who were accompanied by Sir Henry Roscoe (Hon. President), Sir William Ramsay (Acting President), and Mr. William Macnab (Hon. General Secretary).

The following delegates had the honour of being presented to the King by Sir Henry Roscoe:—Dr. William H. Nichols (America), K. K. Regierungsrat Frederick Strohmer (Austria), Dr. Francis Sachs (Belgium), Mr. Ou Kouanze (China), Prof. Léon Lindet (France), Geh. Regierungsrat Prof. Dr. Otto N. Witt (Germany), Prof. Emanuel Paternò (Italy), Prof. Kuhara (Japan), Dr. S. Hoogewerff (Netherlands), N. Tavildaroff (Russia), Prof. Pierua y Alvarez (Spain), Prof. Arrhenius (Sweden), and Monsieur F. Reverdin (Switzerland).

CLOSING MEETING OF THE CONGRESS, WEDNESDAY. JUNE 2ND, 1909.

The PRESIDENT, Sir William Ramsay, announced that the Congress had been attended by 3000 members and 650 ladies.

The reports of the presidents of sections were then read. Out of a total of 105 papers presented to the section of Analytical Chemistry 60 were read and discussed. The section of Inorganic Chemistry and Allied Industries heard and discussed 47 papers. In the Metallurgical section, 52 papers were discussed, and 32 in the Explosives section. The papers presented to the section of Organic Chemistry and Allied Industries numbered 111, of which 60 were read. The number of communications read and taken as read before the section of Colouring Matters and their Application was 52. At the meetings of the section of Physiological Chemistry and Pharmacology 66 papers were presented and 46 were read. The Industry and Chemistry of Sugar section heard 68 papers read, the Starch section 29, the Fermentation section 58, and the Agricultural Chemistry section 43. At the meetings of the Hygiene section 36 papers were presented and 28 were read and discussed. The Electrochemical section heard 87 papers. The Pharmaceutical section received 44 papers, and of these 40 were read. Of 85 papers received by the Bromatology section 42 were read; and the ninth section, that of Photography, considered 27 papers.

Various resolutions received from the sections were adopted, but several from Section XI., dealing with the patent laws, were dropped, as no one was present to explain and support them.

On the proposition of M. LINDET, it was resolved to continue the International Commission on Analyses, with a grant of 2000fr.

Invitation from the United States.

MR. WHITELAW REID said that, at the request of the American delegates, he was there to present on their behalf and on behalf of the United States people, an official invitation that the next meeting of the Congress should be held in the United States. The Ambassador then read a letter from the Secretary of State of the United States intimating that the President had approved a joint resolution of the Senate and the House of Representatives authorising the President to invite the International Congress of Applied Chemistry to hold its eighth meeting in the United States of America in 1912. Perhaps the people of the United States might not be able to surpass the splendid hospitality with which the Congress had been received in London, but they would do their best to rival it. The delegates, if they accepted his invitation, would go next to a country which looked especially on the work of science as, above all, tending to promote happiness and diffuse peace among the nations of the earth.

Dr. H. W. WILEY, of the Department of Agriculture, Washington, supported the invitation, and said that according to the last census over 10,000,000 of the citizens of the United States had been born in foreign lands. Thus, an eighth of the whole population of the United States were foreigners who had been received into citizenship. The delegates of every nationality could count upon being welcomed in their own tongue.

Prof. R. MELDOLA, representing the Society of Chemical Industry, who also supported the invitation, said it was the first time in the history of the Congress that the delegates had received a direct message from the ruler of a great nation asking them to meet in his country.

The invitation was accepted with acclamation.

The PRESIDENT then proposed that Professor E. W. Morley should be the Honorary President of the eighth Congress, and that Dr. W. H. Nichols should be the Acting President.

Dr. WITT seconded the proposal, and said the success of the Congress hitherto had been largely due to a circum-spect choice of presidents.

Prof. BASKERVILLE supported the resolution, and it was carried unanimously.

Dr. WILEY proposed that the official American delegates to the seventh Congress should be constituted the Organising Committee of the eighth Congress, with power to add to their number.

Prof. F. W. CLARKE (Washington) seconded the resolution, which was carried.

The PRESIDENT proposed that a permanent officer (Délégué des Présidents) should be appointed by the International Commission of the Congresses of Applied Chemistry. Sir William Ramsay said it was usual for such congresses as theirs to have a permanent official to carry on the record from meeting to meeting and to preserve the continuity of the work of the successive assemblies. It was intended that the permanent official, if one was appointed, should, after publishing the official proceedings of one Congress, take up his residence in the country in which the next Congress was to be held and there give the Organising Committee such aid as it might require. The International Commission, consisting of the former Presidents of the Congress, would make the appointment in consultation with the Organising Committee.

The resolution was carried, as was also a suggestion of Dr. NICHOLS that the expenses of the appointment should be borne by the next Congress.

Sir HENRY ROSCOE moved:—"That all communications to the Congress be submitted to an English Publication Committee on the understanding that they be judged with perfect fairness and impartiality." He said that hitherto papers had frequently been printed in the Proceedings which had already been before the scientific world, and now it was proposed to edit all papers before printing them. It was desired that the volume of Proceedings, which had already become unwieldy, should contain only papers of originality and importance. The English Publication Committee would consist of experts in all branches of science—members of the Chemical Society, of the Society of Chemical Industry, of the Society of Public Analysts, of the Institute of Brewing,

of the Iron and Steel Institute, and other similar societies. If disagreement occurred between an author and the committee the matter would be referred to the Publication Committee of the author's own country, and its decision as between the English committee and the author would be final.

Prof. CARL DUISBERG recorded the resolution, which was adopted.

The following delegates then expressed their thanks for the entertainment which had been extended to the members of the Congress whilst in London:—M. Lindet, a past president, who specially referred to the hospitality of the English ladies and to the work of the organising committee; Dr. F. P. Lavalle (Argentina), Dr. Strohmer (Austria), M. F. Sachs (Belgium), Mr. Ou Kouanze (China), Dr. Louis E. Mourgues (Chile), Prof. Armand Gautier (France), Prof. von Bubka (Germany), Senatore E. Paternò (Italy), Prof. Mitsuho Kohara (Japan), Dr. Hoogewerff (the Netherlands), Dr. H. Mastbaum (Portugal), Prof. M. T. Lecco (Serbia), Prof. E. Piñerúa y Alvarez (Spain), Prof. P. Klason (Sweden), Prof. E. Bosshard (Switzerland), and Dr. D. T. Day (United States of America).

The PRESIDENT added an expression of thanks to the University of London and the Imperial College of Science and Technology for the use of their buildings, and then declared the seventh Congress closed.

Birmingham Section.

Meeting held at Birmingham University on Thursday, March 18th, 1909.

MR. HARRY SILVESTER, B.Sc., F.I.C., IN THE CHAIR.

THE CHEMIST'S RELATION TO THE COPPER AND BRASS INDUSTRIES.

PART II.

BY ERNEST A. LEWIS.

In a previous paper I have dealt with the chemist's relation to the copper and brass industries as far as the management of the works is concerned (this J., 1908, 479–482). I now bring forward some suggestions for the analysis of various metals, ores, and residuals used in the trades.

The determination of moisture in ores and residues causes considerable trouble and loss, owing to different chemists using different methods. Moisture, from a smelter's point of view, represents, in addition to water, organic matter.

Different materials need different methods of determining moisture. Material containing finely powdered metallic copper, such as precipitate, will rapidly oxidise and gain weight if heated over a direct flame, but a sulphide ore will either lose weight owing to sulphur burning away, or gain weight owing to oxidation, depending on the heat used. Thus a suitable method must be used for each class of product.

Ores are best dried at 100° C. The quantity taken (50 to 100 grms., according to the fineness of the ores) is spread out in a thin layer; in the case of a sulphide ore too prolonged heating, even in a steam oven, will cause oxidation. To dry a sulphide ore in a pan over a flame is objectionable although it is often done.

Copper precipitate.—Two lots of 200 grms. each are dried for 4 hours in a steam oven, and reweighed after a further 1 hour's drying to ensure the weight being constant. The use of a higher temperature leads to inaccurate results; this material usually contains straw, fibres, and similar organic matter, and to attempt to remove this will lead to oxidation of the copper.

Rich copper scale.—Many sellers insist upon this material being dried in a steam oven, so that only moisture is driven off, whilst the smelters dry it over a flame to drive off oily matter. The determination of moisture is made by heating two lots of 200 grms. each of the scale in porcelain dishes over a small rose flame until the water is driven off, then the heat is increased until

the oil comes off; the scale must be stirred continuously, and immediately vapours cease coming off the heating must be stopped.

Shop sweeps and similar residues.—Two lots of 500 or 1000 grms. each are dried in an iron pan over a flame until all vapours are driven off and all organic matter decomposed. The samples for analysis must be taken from the dried material.

Methods of copper assay.—Two methods of assaying copper can be relied upon to give accurate results; they are the electrolytic method and the iodide assay. To determine copper it must be separated from the gangue and matter mixed with it.

A copper ore can usually be crushed to go through a 90 sieve. Two grms. are treated in a porcelain dish with 15 c.c. of *Aqua regia*, until decomposed; the cover is washed and the solution evaporated to dryness, the residue dissolved in 15 c.c. of fuming hydrochloric acid and again evaporated to dryness. The residue is now extracted with 10 c.c. of hydrochloric acid and about 50 c.c. of hot water, and the solution is filtered into a beaker, at the bottom of which is a piece of thin zinc stick about 2 inches long. The residue is well washed with hot water. The solution is heated for about $\frac{1}{2}$ hour on the hot plate to precipitate the copper, which is then filtered off, washed, and is dissolved in nitric acid, using 4 c.c. for each grm. supposed to be present; if a very rich ore is used, the solution must be diluted and an aliquot part used for the determination assay. The zinc is cleaned with nitric acid as described below. In the case of a very poor ore, double the above quantities are used.

The sample of residue, as received by the chemist for assay, usually has a sample of metallics in the packet. Some chemists crush the fines to go through a 90 sieve, weigh out 1 or 2 grms. of the proportion of fines and metallics, decompose with nitric acid, filter off the silica and electrolyse. This method is doubtless satisfactory for some products, such as copper scale, but for others it is unsuitable. The method I adopt for all these residuals, such as ashes, sweeps, concentrates, precipitates, etc., is to assay the metallics separately, using about 0.4 grm., and estimate the copper by the iodide method. The fine material, which should have been crushed to go through a 30 sieve before it reaches the laboratory, is crushed to go through a 60 sieve; there is no need to use a finer sieve: if there are any metallics which will not go through a 60 sieve they must be cut up as fine as possible—there is no need to separate them and assay separately. The fines are thoroughly mixed and 10 grms. evaporated to dryness in a 500 c.c. Jena flask with 20 c.c. of nitric acid and 50 c.c. of hydrochloric acid. When cool the residue is moistened with 30 c.c. of hydrochloric acid, boiled until all nitrous fumes are driven off, diluted with about 100 c.c. of hot water, and boiled for 10 minutes; if any of the material sticks to the flask it must be loosened with a glass rod. The solution is then filtered into a 500 c.c. Jena lipped beaker, at the bottom of which are 2 pieces of thin zinc stick, weighing about 20 grms. After washing, the beaker is put on the hot plate for 15 minutes until the copper is all deposited. The spongy copper is filtered off, well washed with hot water, and washed into the beaker, whilst the pieces of zinc are transferred to a test tube. 10 to 20 c.c. of nitric acid (according to the amount of copper) are poured on the zinc, and as soon as the effervescence commences the acid is poured into the beaker and the zinc washed with about 10 c.c. of cold water, and a further 10 to 20 c.c. of nitric acid is poured into the beaker. The cleaning of the zinc must be carried out quickly and the zinc must be instantly washed with water. Every trace of copper is removed from the zinc. The copper is dissolved by boiling on the hot plate for at least 10 minutes. The solution is cooled and diluted to 500 c.c., and, according to its richness in copper, 25, 50, or 100 c.c. are taken for the iodide assay, and 50 or 100 c.c. for the electrolytic assay. The percentage of metallics and fines being known, a simple calculation will give the percentage of copper in the residue.

To estimate the copper in a pure copper scale, 10 grms. of the powdered material are dissolved in 40 c.c. of nitric

acid and 40 c.c. of water, boiled to expel acid fumes, diluted, and filtered into a 500 c.c. measuring flask; 50 c.c. are electrolysed after adding 10 c.c. of sulphuric acid and diluting to about 250 c.c.

Assay of brass borings.—The accurate estimation of copper in samples of brass borings is not easy. Brass borings are often bought in large quantities without analysis. I have recently come across cases of adulteration with sand; in one case nearly 20 per cent. being present, which could not be seen by casual inspection. Borings often contain from 1 per cent. to 3 per cent. of oil. If the sample contains any large pieces they must be cut up to get the whole sample of an average size. Then 10 grms. are heated in a large porcelain crucible, over a small rose flame, to drive off oil; immediately the evolution of fumes ceases the crucible is allowed to cool and weighed. The borings are transferred to a 500 c.c. lipped beaker, with 40 c.c. of nitric acid and 40 c.c. of water, and when the metal is dissolved the excess of acid is boiled off. Any sand or tin can easily be seen on diluting. Brass borings do not as a rule contain tin except in very small quantity. If tin and sand are present, they are best weighed together after ignition, the tin is reduced in hydrogen, dissolved in hydrochloric acid, precipitated with pure zinc, digested in nitric acid, and weighed as oxide. The sand is determined by difference. The filtrate from the tin and sand is received into a 500 c.c. measuring flask; 250 c.c. are evaporated with 20 c.c. of sulphuric acid to separate the lead, and iron precipitated by means of ammonia, as usual, and weighed as ferric oxide. The copper is determined in 50 c.c. of the original solution by electrolysis or in 25 c.c. by the iodide assay. For technical purposes the zinc is taken by difference. Manganese bronze borings, after separating the tin and sand (if present), are analysed as described or manganese bronze below. When it is desired to find the percentage of free iron in borings, 20 grms. are washed with ether to extract oil, and the free iron picked out with a magnet and weighed.

Cum-metal borings.—10 grms. are heated to remove oil, and digested with 60 c.c. of nitric acid and 60 c.c. of water, the solution is filtered, and any tin and sand is ignited and weighed. The precipitate is macerated in a small mortar, a portion weighed into a boat and reduced in hydrogen; the tin is separated by means of pure zinc, and oxidised with nitric acid. The stannic oxide obtained is sufficiently pure for a technical assay. The filtrate from the nitric acid may contain a little copper and lead, and is added to the main portion and diluted to 100 c.c. as described under brass. The zinc used for reprecipitating the tin must, of course, not be dissolved. Samples of copper borings cannot always be accurately sampled by taking a small portion; the only way to analyse such samples is to weigh out 50 grms., dissolve in nitric acid, dilute it, and use one-fifth part for the analysis.

The electrolytic determination of copper.—As much of the alloy as contains about 0.8 gm. copper is dissolved in 4 c.c. of nitric acid and 4 c.c. of water (in the case of an metal, 5 c.c. of each of acid and water); the solution is heated on the hot plate, without boiling, until greasy streaks run down the side of the beaker, diluted with water (any tin present being now filtered off), 2 c.c. of sulphuric acid added, and diluted to about 250 c.c., any lead being allowed to settle. The solution is now electrolysed in the usual way. I have never found any difficulty in precipitating 0.8 gm. of copper in 18 hours, using 4 Daniell cells. If the current can be obtained through a resistance from a lamp, 1.5 grms. can easily be separated in 12 hours, but in this case 12 c.c. of sulphuric acid must be added.

The rapid electrolytic method was recently described by Price and Humphries (this J., 1909, p. 121).

The only other reliable method of copper assay is the iodide method. It has been stated that the thiosulphate solution must be standardised every day as it does not keep, but this is not so. I have repeatedly tested solutions after keeping them 6 weeks and using them every day, and there has not been the slightest alteration in strength. Certain precautions must be taken—the solution must be kept in a bottle with a well fitting stopper, in a dark

cool cupboard, free from acid fumes. The burette, containing the solution, when not in use, must be kept full and corked with a sound cork. Another objection urged against the method is that the blue colour returns after a time; but with careful working, there is no danger of this. The solution must be free from nitrites and not too dilute. For all commercial work I use a solution (1 c.c.=0.01 gm. of copper) made by dissolving 40 grms. of "Hypo" crystals in 1000 c.c. of distilled water and filtering the solution; this is standardised against pure copper, the copper contents of which have been accurately determined electrolytically. Three lots of about 0.4 gm. each are dissolved by warming in 500 c.c. flasks, with 4 c.c. of nitric acid and 4 c.c. of water, and the solutions heated on the hot plate until the neck and sides of the flasks appear greasy, and diluted to about 70 c.c.; sodium carbonate solution is added till a decided precipitate forms, when 4 c.c. of 50 per cent. acetic acid is added, the neck of the flask washed, and the solution diluted to about 150 c.c.; the solution is now well shaken with 3 grms. of potassium iodide and allowed to stand for one minute, and then titrated with the thiosulphate solution, 1 or 2 c.c. being run in at a time, and 4 c.c. of starch solution being added when within 3 or 4 c.c. of the end.

An assay of brass, accurate within 0.2 per cent., can be obtained in half an hour by the iodide method; the results are as accurate as the electrolytic methods.

Analysis of commercial coppers.

It is not possible to use one standard method for all coppers. Separate quantities must be weighed out for nearly every estimation.

Copper and lead.—The best method to estimate these two metals in electrolytic copper is to dissolve about 2 grms. in 8 c.c. of nitric acid and 8 c.c. of water as described above, then add 10 c.c. of sulphuric acid, and electrolyse. The lead may be weighed on the spiral as peroxide, but it will probably only be present in traces. When the electrolysis is completed the cone and spiral are rapidly transferred to a beaker of clean water and washed in the usual way. There is no danger of either copper or lead redissolving if this is done quickly; the elaborate washing and syphoning described in some text books is unnecessary. The lead oxide must be washed in distilled water only, not in alcohol.

The analysis of a tough copper or Chili bar is carried out as above, using 1 gm., or 2 grms., if the highest degree of accuracy is required. In the case of a copper containing over 0.2 per cent. of lead the latter should be separately estimated in 1 or 2 grms. in a solution containing only nitric acid, the copper being estimated in a separate lot. Copper cannot be correctly determined in a solution containing only nitric acid, especially if the copper contain arsenic. In the presence of 10 c.c. of sulphuric acid and sufficient nitric acid, arsenic and antimony are never deposited with the copper.

Bismuth must be accurately determined to 0.001 per cent. This can only be done by the colorimetric method. The modification I use is as follows:—10 grms. of the copper are dissolved in 35 c.c. of nitric acid and 35 c.c. water, excess of acid boiled off, and ammonia added until the solution is neutral. Ammonium carbonate solution is then added in excess and the solution kept nearly boiling for 6 hours, when the precipitate is filtered, washed, and dissolved in 4 c.c. of dilute sulphuric acid, and the solution diluted with water to about 150 c.c. 5 grms. of potassium iodide and 5 c.c. of dilute sulphurous acid (1 part of the saturated solution and 10 parts water), are now added, and the solution is boiled, and the cuprous iodide filtered off. If the solution is yellow 2 or 3 c.c. dilute sulphurous acid solution are added; if the colour is permanent, bismuth is present. The solution may be diluted to 500 c.c. and 100 c.c. compared colorimetrically in a Nessler glass, against the colour formed by adding a standard solution of bismuth to a solution of potassium iodide containing a little sulphurous acid. No gravimetric method of estimating bismuth in copper is of any value.

Arsenic.—Various methods of estimating arsenic in copper have been described, the most generally used being the various distillation methods. I have not

found it necessary to add calcium chloride to the ferric chloride mixture to get the whole of the arsenic over, provided fuming hydrochloric acid is used and the distillation carried out slowly. For this estimation, from 2 to 5 grms. of the copper are slowly boiled for $\frac{1}{2}$ hour with 20 grms. of ferric oxide dissolved in 200 c.c. of fuming hydrochloric acid. The solution is then distilled slowly till about 50 c.c. are left. The whole operation takes about 2 hours. All the arsenic is found in the distillate, and is estimated by titration with iodine solution (1 c.c. = 0.001 gm. of arsenic) in the usual way, after neutralising with ammonia, faintly acidifying with hydrochloric acid, and adding a decided excess of sodium bicarbonate (about 3 grms.). If calcium chloride is added to the ferric chloride, the arsenic can be distilled over in a shorter time, but if antimony is present it is liable to come over at the higher temperature and give high results.

Antimony is also conveniently estimated by distillation. The method is described fully by Gibb (this J., 1901, 184). It is best to make a separate distillation for arsenic. The precipitate of iron carbonate containing the arsenic and antimony is dissolved in hydrochloric acid as described by Gibb, the solution evaporated to incipient dryness, after about 0.25 gm. of pure copper is added to reduce arsenic and antimony, hydrochloric acid is added and the solution distilled again (there is no need of a thermometer); the arsenic is completely removed. Zinc chloride solution is added and the antimony distillate separately collected. It is necessary to add 3 additions of 5 c.c. each of fuming hydrochloric acid to remove all the antimony, and the solution must consist practically of fused zinc chloride. For tough coppers 5 grms. are sufficient, for "Best Select" 10 grms., and electrolytic 20 grms.

The electrolytic method gives good results, the antimony and arsenic being precipitated together with iron as basic carbonate, as in the distillation method. The precipitate is dissolved in 5 c.c. of dilute hydrochloric acid and the solution diluted to 100 c.c., treated with hydrogen sulphide, and filtered through a hardened paper, the precipitate being well washed with hydrogen sulphide solution. The antimony and arsenic are dissolved out by passing 10 c.c. of warm sodium sulphide solution several times through the filter, and the solution diluted to 50 c.c., and electrolysed after adding 5 c.c. of hydrogen peroxide solution. It is best to use electrodes of platinum foil about 2 in. by 1 in. The antimony is deposited in from 6 to 8 hours, it can be identified by the usual tests. Owing to the purity of commercial copper nowadays antimony is seldom present except in traces.

Tin is seldom found in copper. If a slight white precipitate forms on dissolving 10 or 20 grms. in nitric acid free from chlorine, the solution is diluted to about 500 c.c., and allowed to stand for 48 hours, after decanting the top liquid, the solution is diluted and digested with 5 grms. of tartaric acid for 4 hours on the hot plate; if the precipitate does not dissolve, it consists of tin and can be filtered off and weighed.

Phosphorus does not occur in refined copper except in minute traces. The method of estimation depends upon the kind of copper. Many manufactured coppers, such as tubes, rods, etc., contain phosphorus. If arsenic is not present 10 grms. are dissolved in nitric acid, and the phosphorus precipitated with ammonium molybdate, and then converted into magnesium phosphate in the usual way. When arsenic is present it must be removed by means of hydrogen sulphide, and the phosphorus estimated in the filtrate.

Sulphur occurs in refined copper in traces only. 10 grms are dissolved in nitric acid, the solution is diluted, 2 or 3 drops of hydrochloric acid added, let stand overnight to remove any silver, filtered through two ashless papers, evaporated twice to dryness with hydrochloric acid, and precipitated with barium chloride. In Chili bar copper 2 grms. are sufficient.

Iron and nickel are estimated by dissolving 10 grms. in 35 c.c. of nitric acid and 35 c.c. of water, boiling off acid fumes, diluting, and electrolysing. If the electric current can be obtained from a main supply, most of the copper can be precipitated after adding 10 c.c. of sulphuric acid, the remainder being precipitated with

hydrogen sulphide. The solution is evaporated to dryness, adding 2 c.c. of nitric acid towards the end. The iron is precipitated with ammonia, and the filtrate electrolysed after adding 1 gm. of ammonium oxalate. If hydrogen sulphide has to be used to separate the copper, the solution is diluted to $\frac{1}{2}$ litres and hydrogen sulphide passed through it for 2 hours. The precipitate is filtered through several filters, previously washed with hydrochloric acid and distilled water to remove iron. The filtrate is boiled to dryness, adding 2 c.c. each of nitric and sulphuric acids towards the end. The iron and nickel are separated as above. It is not necessary to separate cobalt.

Oxygen.—Several processes by reduction in hydrogen have been proposed for this estimation. Archbutt's method is simple and very accurate. The process is described in detail in the Analyst (25, p. 253). The analysis of mattes and similar material can be carried out similar to pure copper, using 5 or 10 grms. according to its purity.

Analysis of spelter.

The only impurities present in sufficient quantity in modern spelter to concern a metallurgist are tin, lead, copper, and iron, very rarely cadmium, and in some splatters aluminium. There is usually a difference in price of 10s. and £1 a ton between distilled spelter and remelted splatters. Very often remelted spelter is of better quality than some distilled splatters, and it is sold as distilled spelter. It is often possible to say whether a spelter is distilled or remelted from the analysis. If copper is detected the spelter is almost certainly remelted. If from 0.2 per cent. to 0.5 per cent. of tin is present as well as copper there is no doubt the spelter is remelted. Nearly all remelted splatters contain over 0.1 per cent. iron. It is said that aluminium is put in remelted spelter to brighten it; but I have never come across any. The effect of cadmium is to cause the spelter to have a fine grained fracture, quite different to ordinary spelter. For lead, tin, copper, and iron, 20 grms. are dissolved in 40 c.c. of sulphuric acid and 240 c.c. of water. If the action is too vigorous, it must be modified by cooling. When the zinc is nearly dissolved the solution is filtered and the precipitate well washed. Iron is determined in the filtrate by titration with permanganate. The precipitate is washed into a beaker, 15 c.c. of nitric acid added, and the whole boiled, diluted to 100 c.c.; if a precipitate of stannic oxide is present, it is filtered off, the filtrate evaporated until copious acid fumes are evolved after adding 10 c.c. of sulphuric acid, diluted with water, allowed to stand 3 hours or better overnight, and the lead sulphate filtered off and washed with dilute sulphuric acid in the usual way: the filtrate can be electrolysed for the remainder of the lead and the copper. This solution frequently contains some of the iron, which can be precipitated with ammonia.

Aluminium, if present, goes into solution with the bulk of the iron; it must be determined on a separate 20 gm. lot.

Cadmium is estimated on a separate 20 gm. lot; part of it dissolves with the iron and can be precipitated by passing a slow current of hydrogen sulphide for at least 2 hours. The portion left with the lead is precipitated by hydrogen sulphide after separating lead as sulphate and any copper by electrolysis. The cadmium is weighed as sulphide on dried filter papers.

In high grade splatters containing 99.8 per cent. of zinc, upwards, the only metals present are lead and iron. It is best to work on 40 grms. At present there is no sufficient accurate electrolytic method of estimating zinc direct in spelter—it is always found by difference. Any method of sampling zinc by rubbing it to powder in a hot ladle is valueless. Several plates must be drilled through in several places to get a good sample.

The complete analysis of lead, tin, and antimony is not required in a copper works, the commercial metals being sufficiently pure. The analysis of aluminium presents no special difficulty. 10 grms. should be taken for the estimation of silicon, copper, and iron. No other metal is present as a rule. The aluminium is calculated by difference.

Nickel.—In the case of cube nickel, a large number of cubes should be broken up, and 10 or 20 grms. dissolved in 80–160 c.c. nitric acid, the solution is evaporated to dryness, after adding 200 c.c. of hydrochloric acid, heated on the air bath for $\frac{1}{2}$ hour, treated with 20 c.c. of hydrochloric acid and water, and the silica filtered off. The filtrate is received into a 1000 c.c. flask; an aliquot part, equal to 1 gm. of nickel, is treated with hydrogen sulphide to remove copper, evaporated to dryness, and 1 c.c. of nitric acid added to oxidise iron, which is precipitated by ammonia as usual. The filtrate is received into a porcelain dish, dilute sulphuric acid added till the free ammonia is neutralised, then a further 5 c.c. of sulphuric acid in excess; it is now evaporated until sulphuric acid begins to volatilise, when water is added, then ammonia in excess and 1 gm. of ammonium oxalate, and the solution electrolysed at 60° C. A separate portion (equal to 5 grms.) of the 1000 c.c. is used for determining copper and iron.

Carbon is usually present in cube nickel, but is not required to be determined for the German silver trades. If necessary, the carbon, which is present in the free state, can be estimated by combustion.

Sulphur is estimated on a separate portion of the 1000 c.c. by precipitation as barium sulphate.

Analyses of alloys.—Alloys can be divided into several classes, such as various brasses, gun metals, manganese bronzes, aluminium bronzes, white metals, and the miscellaneous alloys.

In the analysis of brass copper and zinc are determined on 1 gm. by electrolysis as described for copper, but only 2 c.c. of sulphuric acid is added. The zinc is determined either electrolytically or the ferrocyanide method. From a large experience of the volumetric ferrocyanide method I believe it to be far more accurate than usually supposed provided it is carried out under standard conditions. The solution containing the zinc is evaporated to about 100 c.c., ammonia is added in excess, and the solution just heated to boiling and filtered into a 9-inch basin, with hot water containing a little ammonia; the solution is made just acid with hydrochloric acid, a further 2 c.c. is added, and the solution is diluted to about 700 c.c. and heated to boiling. The ferrocyanide solution (1 c.c. = 0.1 gm. zinc) is added, 2 or 3 c.c. at a time with continuous stirring, to within 3 or 4 c.c. of the end, the solution is again boiled, 1 c.c. of a saturated solution of uranium acetate is added, and the ferrocyanide added a drop at a time, until the solution is faintly brown. The end reaction is very sharp. If a trace of copper is present the end reaction is best obtained with spots of uranium acetate on a white tile in the usual way. The ferrocyanide is standardised against pure electrolytic zinc. The assay is accurate to within .05 per cent., working on 1 gm. of brass.

The determination of traces of tin, lead, and iron is done on 5 or 10 grms. by dissolving in nitric acid to separate tin, evaporating with 20 c.c. of sulphuric acid. All copious fumes are evolved, taking up with water and filtering off the lead sulphate after standing overnight; the iron is precipitated with ammonia as usual. This method is sufficiently accurate for commercial purposes, for exact work the small amount of lead in solution must be separated by electrolysis, and added to the main percentage. An exact analysis requires the separation of the small amount of nickel, which is often present, about 7 grms. are dissolved in nitric acid and the copper separated by hydrogen sulphide or by electrolysis; the solution is evaporated to dryness and the zinc separated by sulphide in an acetic acid solution, as described under German silver. A double separation is usually necessary if it is difficult to get rid of all the zinc by one precipitation. The nickel is determined by electrolysis. In special cases arsenic may be looked for and determined, as described under copper.

The commercial analysis of gun metal is simple, but the detailed accurate analysis is very complex. An ordinary analysis requires copper, tin, zinc, lead, and iron. 1 gm. dissolved in 5 c.c. of nitric acid and 5 c.c. of water, the solution is evaporated until the sides of the beaker appear greasy, diluted to about 50 c.c. with hot water, allowed to stand, and the stannic oxide filtered off,

and washed with hot water. For commercial analyses it can be ignited and weighed as stannic oxide, as it will not contain more than 0.2 per cent. copper. The copper and zinc are determined as in brass, the iron and lead on a separate sample, using from 3 to 5 grms., according to the amount of lead present. If an exact analysis is required the following must be looked for: copper, tin, antimony, arsenic, lead, iron, nickel, zinc, phosphorus, and sulphur. The copper, tin, and zinc are determined on 1 gm., but the small percentage of copper (and lead in gun metal containing over 2 per cent. of lead) must be determined, by fusing with about 2 grms. of a mixture of dry sodium carbonate and sulphur in equal parts, boiling with water, and filtering off the lead and copper sulphides, which are then dried and ignited; the ash is dissolved in a few drops of nitric acid and diluted to 50 c.c. in a small beaker and electrolysed. I use small electrodes of platinum foil. The copper and lead are calculated to oxide and deducted from the stannic oxide, the percentage of copper being added to the main bulk.

The percentage of antimony (which is counted as tin in commercial analyses) is determined on a separate 2 gm. lot. The impure tin oxide is fused with 2 grms. of sodium hydroxide in a silver crucible, the melt dissolved in water, the solution acidified with hydrochloric acid and the antimony precipitated by boiling with iron wire. The antimony is dissolved in 10 c.c. brominated hydrochloric acid and estimated by the bromate method (Chemical News, 95, No. 2462). The percentage of antimony is deducted from the percentage of tin; both oxides contain practically the same percentage of metal.

Arsenic is determined by distillation and the percentage calculated to arsenic oxide and deducted from the tin. Phosphorus is determined on a separate 5 gm. lot; the tin oxide is fused with potassium cyanide and the phosphorus obtained in solution.

If the lead exceeds 3 per cent., it is determined on a 2 gm. lot; the small amount carried down with the tin must be separated by fusion with sodium carbonate and sulphur, and the amount in solution from the lead sulphate precipitate must be estimated electrolytically. Iron is determined in the lead portion. Nickel may be present in small quantity and is separated as described under brass. Sulphur is very often present in quantity up to 0.2 per cent. It is determined by digesting 2 grms. with nitric acid, removing tin, evaporating to dryness with hydrochloric acid, and precipitating as barium sulphate. In the analysis of manganese bronzes, sterling-metal, etc., copper and zinc are determined on 1 gm., practically as described for brass, the only difference being that after evaporating the solution is made just alkaline with ammonia, then bromine is added until a deep red colour appears, when the solution is allowed to stand for one hour, and boiled with excess of ammonia to precipitate iron and manganese; the zinc is estimated in the filtrate. Tin and lead are estimated as in brass, using 5 grms.

Manganese, iron, and aluminium are estimated in a 5 gm. lot, separating the tin as oxide, and copper with hydrogen sulphide or by electrolysis. The filtrate is evaporated to dryness, adding 4 c.c. of nitric acid towards the end; the residue is dissolved in HCl, and iron and aluminium separated by the acetate process; the acetate precipitate is dissolved in hydrochloric acid, and diluted to 250 c.c. In one lot of 100 c.c. the iron and aluminium are precipitated together with ammonia and the iron is titrated in another 100 c.c. The manganese is precipitated with ammonia after adding bromine in the usual way. For the accurate analysis of German silver 1 gm. is dissolved in nitric acid, and the copper separated by electrolysis as for brass. The solution containing nickel and zinc is evaporated to dryness, the residue taken up with water and a few drops of hydrochloric acid, transferred to a 500 c.c. beaker, a solution of sodium carbonate added till a decided precipitate forms, when 100 c.c. glacial acetic acid are added; the bulk of the solution must not exceed 300 c.c. When perfectly cold, a stream of H_2S is passed through the solution for one hour, at the rate of about 2 bubbles per second; the zinc precipitates as pure white zinc sulphide, which can be filtered through 2 Swedish filters, washed with a solution of hydrogen sulphide, and weighed as sulphide. The nickel filtrate

is evaporated with 20 c.c. of sulphuric acid till copious fumes are evolved, diluted, electrolysed for nickel, after adding ammonia and 1 gm. of ammonium oxalate. The above separation is complete so long as the acetic acid solution is perfectly cold and saturated with hydrogen sulphide.

The small quantities of tin, lead, and iron are determined on a 10 gm. lot as for brass. The analysis of cupro-nickel for copper and nickel is best carried out by electrolysis, the copper being separated as under brass, using 0.8 gm., and the nickel in the solution. Nickel electrolyses should always be carried out in a sulphate solution containing ammonium sulphate and 1 gm. of ammonium oxalate. Cupro-nickel coins usually contain 1 per cent. zinc, and are analysed as German silver.

Cupro-manganese is tested for copper, iron, and manganese, 1 gm. is dissolved in nitric acid and the copper separated by electrolysis. The small amount of manganese deposited on the spiral is dissolved in a few c.c. of hot hydrochloric acid, and added to the main bulk, the manganese and iron being separated by the acetate process.

Phosphor-copper is tested for copper and phosphorus. 1 gm. is dissolved in nitric acid and the copper separated by electrolysis, the phosphorus being separated by the magnesia process in the solution from the copper.

Silicon-copper is tested for copper and silicon. 1 gm. is dissolved in 10 c.c. of *aqua regia*, evaporated to dryness, and heated in an air bath to render silica insoluble; the residue is taken up with hydrochloric acid and filtered to remove silica, and the filtrate is evaporated with 10 c.c. of sulphuric acid till copious fumes are evolved and then electrolysed for copper.

Aluminium bronzes.—1 gm. is dissolved in nitric acid and the copper determined electrolytically; the aluminium is determined by precipitation with ammonia for technical purposes, the iron is not determined, as it is only present in small quantity. For its determination 5 grms. are dissolved in nitric acid and the copper separated by electrolysis or hydrogen sulphide; after evaporating the filtrate to dryness and oxidising with nitric acid, the iron is separated by a double precipitation with sodium hydroxide and finally redissolved in hydrochloric acid and precipitated with ammonia.

Aluminium brass is ordinary brass containing 1 per cent. or 2 per cent. of aluminium. The aluminium is separated with ammonia, after separating copper. It is analysed practically the same as ordinary brass.

Phosphor tin.—The only constituent required is the phosphorus. 1 gm. is digested with 10 c.c. of nitric acid, the tin oxide and phosphorus are filtered off, dried, ignited and fused with potassium cyanide, the phosphorus being weighed as magnesium phosphate.

Ferro-zinc.—The only constituents required are iron and zinc. 10 grms. are dissolved in 90 c.c. of hydrochloric acid and 10 c.c. of nitric acid, and diluted to 500 c.c. The zinc is determined in 25 c.c. volumetrically and the iron in another 50 c.c. by bichromate.

White metals may be divided into three groups: 1. The rich tin alloys. 2. The rich lead alloys. 3. The zinc alloys.

There is no satisfactory and simple method which can be applied to all these alloys. In the case of an unknown alloy, a qualitative test must precede the quantitative analysis. The method described by Fresenius is the most accurate; antimony is estimated by the bromate method. In the case of a Babbitt metal containing over 70 per cent. of tin, after getting a representative sample in fine powder, 1 gm. is digested with 6 c.c. of nitric acid and 6 c.c. of water, diluted, and the precipitate, which contains the whole of the tin and antimony, and a little copper and lead is filtered off. The filtrate is evaporated with 10 c.c. of sulphuric acid to remove lead, which is filtered off and weighed. The filtrate is electrolysed for copper and any lead left in solution as for brass, the zinc being determined in the solution. The precipitate of tin and antimony oxides is ignited and weighed, then fused with a mixture of dry sodium carbonate and sulphur, and the sulphides of copper and lead filtered off and determined as described under gun metal. The weights of copper and lead found are calculated to oxides and deducted from the tin and

antimony oxides, as these latter contain the same percentages of metal. From the percentage of mixed metal found, the percentage of antimony found by the bromate method (Chemical News, 95, No. 2462) is deducted, leaving the pure stannic oxide. The bromate method of antimony assay is very accurate; as much as 10 per cent. copper has no effect on it provided the solution after reduction with sodium sulphite is boiled long enough to reoxidise the copper. In the case of rich lead alloys, the oxide precipitate may contain 2 or 3 per cent. of lead, and in alloys containing zinc, some of it is nearly always found with the tin oxide. The potassium bromate standard solution must be kept in a well corked bottle, in the dark and in a cool place, it must be standardised every week.

Bismuth occurs in small quantity up to 1 per cent. in some white metals; it may be separated with ammonium carbonate after removing the lead.

It has recently been suggested in America that standard methods of analysis should be adopted by the copper trade; there is much to be said in favour of such a proposal but there is no one method which will suit every alloy. Two or three methods are wanted which have been proved to give accurate results, and the exact conditions of working must be known, and it is with a view to help to get standard conditions in the copper and brass industry that this paper has been written.

DISCUSSION.

The CHAIRMAN said similar standardisation work was undertaken some years ago, as far as iron and steel were concerned, by a committee of the British Association, and although he believed no standard methods had been laid down, the investigation was a most useful one, as it had brought to light errors in processes that were in constant use in many laboratories. In agriculture—particularly in America—official methods of analysis had been laid down and in this country, too, quite recently the Board of Agriculture had scheduled processes to be followed in the valuation of feeding stuffs and manures. Mr. Lewis suggested that in a certain material the moisture should be determined by heating the sample in a porcelain capsule over a naked flame, a second heating at a higher temperature being employed to ascertain the organic matter. That was a barbarous procedure, which ought not to find a place in any laboratory—works or otherwise—for the valuation of copper-containing material. As regards the uniform relative accuracy of the electrolytic method and the iodide method for the determination of copper, his personal experience was distinctly in favour of the former. The analysis proceeded automatically, and the turn of the balance did not permit the uncertainty that the returning colour occasionally did in the volumetric method. Mr. Lewis stated that the presence of cadmium altered the fracture of the spelter. What was the least percentage present in the metal that could readily be detected by the eye of an experienced man?

Dr. T. S. PRICE said he did not consider one evaporation with hydrochloric acid sufficient to get rid of nitric acid; he always evaporated several times. Why were 250 c.c. of electrolytes used for the electrolysis of copper solutions? In his paper (this J., 1909, 117) Mr. Lewis rather criticised the small volume of electrolyte used. Now an essential principle in electrolytic analysis was to use a small a volume of electrolyte as possible in order to get out the last traces of copper. He thought 150 c.c. was plenty. Had the author accurately calibrated his measuring flasks, pipettes, and burettes, and did he take those calibrations into account when doing his assay? If he did not, the iodide assay could not be as correct as the direct electrolytic analysis. Thio-sulphate solution might keep well in a concentrated solution, but it did not keep in dilute solution, say a N/50 or N/100.

He (Dr. Price) also called attention to the molar apparatus in which the bottle was directly connected with the burette all the time. In the electrolytic assay of lead in fairly pure brass, to what temperature was it necessary to heat the lead peroxide formed, in order to drive off the water and get it of constant weight? He believed it was about 230° C. In regard to the suggestion of estimating nickel electrolytically from a solution containing ammonium oxalate he (Dr. Price) pointed out that

in numerous papers it had been shown that carbon was always deposited with the nickel. The accurate method was to use a strongly ammoniacal solution of the sulphate, ammonium sulphate being added to make the electrolyte conduct better. It was not even necessary to have the nickel present as sulphate, as had been recently shown; it could be present as nitrate or chloride, so long as the solution was strongly ammoniacal and contained ammonium sulphate.

Prof. T. TURNER said the first move in the direction of standardisation of metal analyses was the production of a series of samples of standard steels by the International Committee, through its English section, in connection with the British Association. He (Prof. Turner) was the custodian of these samples, which were still available for reference. A great deal had been done recently in other directions in connection with the analysis of cast iron; and the American Foundrymen's Association had appointed a committee and issued suggestions for standard methods for cast iron. The Brassfounders' Association of America was considering the question of standard methods for the analysis of brass. Mr. Stead was reading a paper at the forthcoming International Congress of Applied Chemistry on the standard methods for iron and steel. He (Prof. Turner) had recently received a copy of a report prepared by a number of American chemists, the object of which was to introduce standard methods for the sampling and analysis of iron ores. Some of the suggestions in this report were very interesting. For instance, they had been in the habit of estimating moisture on a relatively small sample. The standard method now adopted by the whole of the chemists in connection with the Carnegie steel plants and others in America was to use 2 kilos. for the estimation. Another suggestion made in this report was the precipitation of manganese by ammonium persulphate. Personally he thought that method was likely to be an improvement on the bromine method, as the use of bromine in the laboratory was always somewhat objectionable. He would be glad to have fuller particulars of the cyanide process for separating phosphorus from the tin residue—the phosphor-bronze.

Mr. J. M. LEVY pointed out, in connection with the assay of copper materials at the smelters, that one generally required to know the percentage of copper very rapidly to control the furnace working. One had to use either the cyanide assay or the rapidly rotating electrode. Many smelters still relied on the cyanide assay as being sufficient to give a good idea of the amount of copper in the matte during the furnace run. He regarded the use of zinc for separating copper as an extremely good method. He had done a fair amount of work on this method; it had an advantage in that one was enabled to do two assays at once, if one had to estimate iron as well as copper. The iron could be determined at once, and the reduction of iron acted as an indicator, for when the iron was reduced all the copper had been precipitated. Would not Mr. Lewis recommend the ferric chloride method in precipitating arsenic and antimony as the arseniates and antimonates of iron instead of the prolonged complex distillation?

Mr. A. E. JOHNSON said he preferred the electrolytic method with rotating electrodes for determining copper, iron, and nickel, both on account of its rapidity and accuracy. Mr. Lewis mentioned in his description of the arsenic distillation method that no thermometer was needed, but if antimony were present, and one did not carefully watch the distilling flask, it was liable to go up to such a temperature that the antimony would come over and would then be titrated as arsenic to give high results. He testified to the usefulness of the suction method for filling burettes by clamping each burette to a bottle and arranging it that the solution might be sucked from the bottle. This method saved much time. Why did Mr. Lewis separate the copper in estimating manganese and iron in manganese bronze? Why not take a large quantity, separate out the tin and lead in the way done for brass, then precipitate the iron and manganese together by ammonia, filtering off and estimating them separately after re-solution and re-precipitation from the combined precipitates?

Mr. F. H. ALCOCK said that thiosulphate solutions weaker than 40 grms. per litre did not keep at all well. It

was thought that the decomposition was set up by sulphur-loving bacteria. The addition of a few drops of carbon bisulphide improved its keeping properties. He kept his decinormal solution in a stoppered amber-coloured bottle and in the dark. The starch solution mentioned would keep six months or more if a little benzene were added to the mucilage at the time of making. A mixture of potassium iodide solution and starch mucilage would not keep; it would quickly develop a blue colour, but with a little benzene it would keep for at least three years. Had Mr. Lewis met the presence of cobalt in spelter? He had found recently spelter containing traces of this element, but did not know its source. Some of the methods described were rather costly. For example, in separating zinc from nickel, 100 c.c. of glacial acetic acid were used. He thought the word determination of percentage should be used in "estimation," for the latter applied more to pecuniary value. Had Mr. Lewis ever determined the amount of zinc in white metals by rendering the solution slightly alkaline with sodium bicarbonate and then adding a solution of potassium cyanide in excess as passing through the solution so prepared sulphuretted hydrogen which eliminated the zinc as sulphide? He could then proceed easily with the copper and nickel determinations.

Mr. LEWIS, in reply, said that all methods of analysis in the copper trades were adopted solely from a commercial point of view, copper being a comparatively expensive metal. It might seem a barbarous method to determine moisture in copper scale by heating in a porcelain dish until all fumes are driven off, yet if scale were bought, the moisture contents of which had been determined by heating in a steam oven for 5 or 6 hours, and then sold it to a smelter who removed 2 per cent. of oil by heating in an iron pan, each percentage of oil meant a loss of 10s. per ton. He did not know the smallest percentage of cadmium required to alter the fracture of zinc, but 0.5 per cent. turned the coarse crystalline fracture into a very finely crystalline one, and 0.2 per cent. gave quite a different fracture to ordinary zinc. To remove nitric acid completely he always evaporated to dryness twice with fuming hydrochloric acid. In regard to the bulk of solution used in an electrolytic copper assay, when using stationary electrodes and about 1 gm. of copper, if the deposition of copper is facilitated by using a concentrated solution the deposition of impurities such as arsenic is also facilitated. There was a great difference in depositing copper from a chemically pure salt and depositing it from commercial bar copper.

Accurately graduated apparatus for the iodide assay could be obtained at rather a higher price than ordinary graduated apparatus. He used one burette for that work only. He used to keep the thiosulphate solution in a self-filling burette, but abandoned it, as it was impossible to keep the solution under the conditions necessary to keep it from deteriorating, namely, in a cool, dark place, free from acid fumes; such a condition was difficult to obtain in an assay laboratory.

As regards the weighing of lead peroxide deposited electrolytically, he only estimated the small amount left in solution after separating the bulk with sulphuric acid; as it only amounted to a few mgrms. it made no practical difference whether it was dried at 100° C. or 200° C. In the case of commercial copper containing over 0.2 per cent. of lead, he heated it at about 200° C. He never estimated large quantities of lead electrolytically. It was quite true that in presence of 5 or 6 grms. of ammonium oxalate in a nickel electrolytic assay, using a concentrated solution, the deposited nickel contained carbon, but if only 1 gm. were added and the solution diluted to 250 c.c. the nickel did not contain carbon. He had noticed a deposition of carbon on the spiral. The presence of ammonium sulphate was essential to get a good deposit. The estimation of arsenic by co-precipitation with iron was doubtless necessary in the assay of ores and mattes, but was not necessary in refined copper.

Mr. Johnson's remarks about distillation of arsenic and antimony were quite correct when using a concentrated solution and very little acid, but in presence of a large amount of hydrochloric acid the arsenic came off long before the temperature is raised sufficiently for the antimony to come over. In the precipitation of iron,

manganese, and aluminium together in an ammoniacal solution of copper, it was difficult to get all the aluminium out of solution, and the separation of the copper from a large bulk of iron precipitate was difficult. The copper must be separated first. He had never come across cobalt in zinc. He had not tried separating zinc from nickel and copper in a cyanide solution. The separation of phosphorus in the tin oxide precipitate was an old process; the precipitate was fused with about 2 grms. of pure potassium cyanide for 2 or 3 minutes to reduce the tin to metal, the phosphorus forming phosphate. It was extracted with hot water and filtered into a porcelain dish, 40 c.c. of hydrochloric acid added, the filtrate evaporated to dryness, and the residue taken up with a few drops of hydrochloric acid and about 20 c.c. of water; the solution is filtered, 1 gm. of citric acid dissolved in water added to the filtrate, then ammonia in excess, any precipitate formed being filtered off. 20 c.c. of magnesia mixture were then added, and the precipitated phosphate weighed in the usual way; the total volume of solution should not exceed 150 c.c.

New York Section.

Meeting held at Chemists' Club on Friday, April 23rd, 1909.

MR. MAXIMILIAN TOCH IN THE CHAIR.

THE DETERMINATION OF COTTONSEED HULLS IN COTTONSEED MEAL.

BY G. S. FRAPS.

Comparison of the composition of cottonseed meal and cottonseed hulls leads one to suppose that it should be possible to secure a reagent which would remove cottonseed meal almost completely, while affecting the hulls to a slight extent only. This is the principle upon which the proposed method for estimating hulls in cottonseed meal is based. The method adopted after a considerable number of trials is as follows:—

Two grms. of the meal are extracted with ether on a hardened filter paper, transferred to a tall beaker, and

200 c.c. of boiling water and 20 c.c. of $N/5$ sodium hydroxide solution are added. A round-bottomed flask filled with water is placed on the beaker to act as condenser, and the whole is boiled for thirty minutes, filtered through a thin layer of asbestos and a three-inch Hirsch funnel, the residue washed thoroughly, transferred to a porcelain crucible, and dried to a constant weight, weighed, ignited, and weighed again. The loss in weight is the insoluble residue. In order to apply this method, it is necessary to know the quantity of insoluble residue yielded by cottonseed hulls, and by cottonseed meal of high purity.

Seventeen samples of meal were sifted to remove hulls as thoroughly as possible. The quantity of insoluble residue was found to be as follows:—Maximum, 13.33 per cent.; minimum, 8.22 per cent.; average, 10.46 per cent.

Sixteen samples of meals of high purity were selected. They contained from 4.85 to 6.73 per cent. of crude fibre, and yielded the following amounts of insoluble residue:—Maximum, 14.09 per cent.; minimum, 9.75 per cent.; average, 11.38 per cent. None of these samples was free from hulls. It appears probable that a meal free from hulls should contain less than 10 per cent. of insoluble residue, estimated according to our method. While a meal containing 10 per cent. insoluble residue contains some hulls, a meal yielding this quantity of insoluble residue is certainly of high purity.

Twenty samples of cottonseed hulls were subjected to analysis, with the following results:—Maximum, 77.87 per cent.; minimum, 69.01 per cent.; average, 75.22 per cent. It appears that hulls yield 75 per cent. insoluble residue, on an average. For the approximate estimation of cottonseed hulls in cottonseed meal, the following method is therefore proposed:—

Determine the quantity of insoluble matter as previously described. Subtract 10 per cent. from the percentage found to be present, and add one-third of the residue. The total is the approximate percentage of hulls in the meal, in excess of the quantity in meals of highest purity. Suppose, for example, 15 per cent. of woody fibre is present in a given meal; subtracting 10 per cent. and adding one-third of the remainder gives us 6.66 per cent. excess hulls present. The quantity of hulls which should be allowed in meal is a subject of further study.

Credit is due to assistant chemist, J. T. Cruse, for most of the analytical work referred to above.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—8d. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs Bourgeois, Paris (3e.).

German.—1 mark each (with full particulars) to Kaiserlich Patentamt, Berlin, Germany.

I.—PLANT, APPARATUS, AND MACHINERY.

PATENTS.

Raising liquids; Apparatus for — H. P. W. Esping, Nässjö, Sweden. Eng. Pat. 9283, April 29, 1908.

A VESSEL provided with a valved liquor inlet and a liquor outlet is suspended in the body of the liquid which is to be elevated, being hung from one arm of a bent lever supported above the liquid tank. A second similar vessel or a counterpoise is suspended from the other arm of the lever. The fulcrum of the lever is situated below the level of the point of attachment of the vessels. The first vessel is also connected to a supply of compressed air by a flexible pipe and the liquor outlet is connected to the valved rising main by another flexible pipe. The supply of compressed air is controlled by a valve operated by the lever. The apparatus works in the following manner: When the vessel is full of liquid, it sinks and pulls over the lever, opening the air valve. Compressed air enters the vessel and forces the liquid out through

the rising main. As soon as the liquid has been forced out by the compressed air, the vessel rises, the lever is reversed, shutting the air off, and the vessel commences to fill again.—W. H. C.

Mixing, kneading and working up materials. O. Bertram Halle a/S., Germany. Eng. Pat. 12,076, June 3, 1908. Under Int. Conv., March 25, 1908.

To ensure thorough mixing, either the material or the support carrying the kneading tool, or both, are subjected to an intermittent rotary movement relatively to the operating movement. This is effected by imparting to the material or the vessel containing it an intermittent movement and to the tool a continuous swinging or rocking movement.—W. H. C.

Separating solids [peat] from liquids; Centrifugal machine for — A. J. Boulton, London. From W. H. Bradley Chicago, Ill., U.S.A. Eng. Pat. 25,300, Nov. 24, 1908. The peat is first crushed until it forms a mixture of the consistency of cream and this is then fed continuous

through the pipe, 1, into the centrifugal separator chamber, A, A¹, A², which is rotated from below. It passes over the spreader plate, 33, into the separating chamber, 45, provided with radial plates, A⁴, to prevent the liquid washing away the solid matter. The latter passes to the annular compacting chamber, 2, from the upper part of which it is forced out by means of the plough, 52, through the conduit, 53. The liquid is discharged through the radial openings, 4.—W. H. C.

Separating and sorting materials. C. Seck, Dresden, Germany. Eng. Pat. 4684, Feb. 25, 1909.

THE materials to be separated are passed between rollers and fed through a shoot formed by two endless webs rotating in the same direction on to a rapidly rotating roll or disc formed either of hard or resilient material. The particles rebound from the roll or disc at different angles according to their size and specific gravity, and are collected in separate receivers placed below.—W. H. C.

Pyrometer. C. B. Thwing, Philadelphia, Pa. U.S. Pat. 919,399, April 27, 1909.

THE pyrometer consists of a tube having a non reflecting, heat-absorbing inner surface. The tube has an opening at the outer end provided with a protecting shield of mica and a thermo-electric couple at the inner end. The heat radiations gathered by the tube are concentrated upon the junction of the thermo-couple by a bright unnel-shaped reflector.—W. H. C.

Distilling apparatus. M. B. Blouko, Chicago, Ill. U.S. Pat. 919,685, April 27, 1909.

THE still has a corrugated bottom which is provided with a flushing discharge port on one side. The still is fed with warm water from the condenser jacket, the inlet being on the opposite side to the flushing discharge port and provided with a deflecting plate within the still to direct the water on to the bottom during the flushing operation.—W. H. C.

Kiln. F. Macarthy, Assignor to Sayre and Fisher Co., Sayreville, N.J. U.S. Pat. 919,902, April 27, 1909.

THE claim is for a kiln built above a series of flues having re-grates at one end. The fire-gases pass from the flues to the kiln through openings in the floor of the latter. The openings in the floor are provided with dampers operated through openings in the side walls of the kiln.—W. H. C.

Drying apparatus. R. Grauer, Los Angeles, Cal. U.S. Pat. 920,050, April 27, 1909.

A NUMBER of semi-cylindrical perforated troughs having semi-cylindrical perforated covers and screw-conveyors adapted to move the material forward are arranged one above the other in a casing. Fans are arranged between the troughs to produce a current of air through the perforations. The material to be treated is fed into one end of the uppermost trough and is discharged from the opposite end into the trough next below and so on to the

lowest trough from which the material is discharged. It may then, if desired, be elevated to the uppermost trough of a second series and so on.—W. H. C.

Heating solid, liquid, or gaseous bodies, by utilising the heat of reaction of the combination of sulphur with other bodies, chiefly metals. A. Lang. Fr. Pat. 395,536, Oct. 21, 1908.

A MIXTURE of powdered or melted sulphur with an appropriate metal is placed in a tube and the reaction is started by the application of a high temperature, obtained by igniting an incandescing mixture, to any point of the sulphur mixture. The tube is placed in contact with the material it is desired to heat.—W. H. C.

Filter with laths (Venetian shutters) for liquids or gases. A. Tixier. Fr. Pat. 395,542, Oct. 21, 1908.

THE principle of the filter is based upon the arrangement of the filtering material (sand) in what is practically a U-tube having one leg longer than the other, the sand being confined by laths, and filtration being possible in either direction. The impure liquid from the reservoir, a, passes through the valve, j, and enters the space behind the curved shield, i, which prevents the disturbance of the surface of the sand, f, retained by the laths, h, and the partition, c. The liquid passes through the sand, f, d, and is discharged through the layer of pebbles, g, into the filtered-liquid reservoir, b. When it is necessary to clean the filter, the valve, j, is closed, and k opened and the water flows out of k, carrying away any deposit and some of the sand. The sand thus carried away is washed and returned to the filter through m. When it is necessary to change the whole of the sand, the valve, o, is opened and the sand flushed out.—W. H. C.

Filtering liquids. C. H. Perrin. Fr. Pat. 396,061, Dec. 16, 1907.

THE apparatus is practically a filter-press arranged vertically, the pasty or fibrous filtering medium being supported on perforated trays.—W. H. C.

Filtration of liquids. J. Resines. Fr. Pat. 396,173, Nov. 9, 1908.

THE liquid is fed into the drum of a centrifugal machine and is driven by the centrifugal force through the cylindrical portion of the drum, which is formed of a suitable filtering medium, the impurities being retained by the latter.—W. H. C.

Pulverisation, dispersion, and mixing of liquids; Process and apparatus for the —. Pagès, Camus, et Cie. and P. Bardy. Fr. Pat. 396,476, Jan. 27, 1908.

THE claim is for an atomising jet in which the angle of dispersion and the length of the jet of atomised liquid are adjusted and regulated by simply adjusting the speed and pressure at which the liquid or liquids enter the gyratory chambers or channels of the atomiser.—W. H. C.

Vaporisation and concentration of liquids by atomisation. Pages, Camus, et Cie. and P. Bardy. Fr. Pat. 396,622, Jan. 31, 1908.

THE claim is for effecting the evaporation of liquids, the generation of steam, the washing of gases with liquids, and other analogous operations by delivering the liquid into the apparatus in the finely-divided condition produced by atomisation.—W. H. C.

Absorption and reaction towers; Automatic sprinkling device for —. F. Klute and H. Ising. Ger. Pat. 209,276, April 16, 1907.

THE sprinkling liquid flows from the supply tank into a vessel provided with a float-valve. From this vessel several valved outlet pipes lead into a common pipe connected with the supply pipe of the distributing device above the tower. In order to vary the amount of liquid supplied to the distributing device, one or more of the valves are completely opened or closed. In the usual forms of apparatus in which the supply is regulated by partially opening or closing the valve in the single pipe leading from the vessel containing the float-valve, the narrow opening thus left is liable to become obstructed by foreign matter.—A. S.

Drying machine; Continuous —. J. Black, A. H., II., and A. B. Lennox. Newcastle-on-Tyne. U.S. Pat. 924,351, May 11, 1909.

SEE Eng. Pat. 4155 of 1908; this J., 1909, 234.—T. F. B.

Filter; Mechanical pressure — for water. E. H. Alvord. Fr. Pat. 396,481, July 25, 1908.

SEE U.S. Pat. 891,996 of 1908; this J., 1908, 886.—T. F. B.

II.—FUEL, GAS, AND LIGHT.

National Physical Laboratory. Memorandum as to photometric units. May, 1909.

IN order to determine as accurately as possible the relations between the photometric units of the United States, France, Germany, and Great Britain, comparisons have been made at different times during the past few years between the unit of light maintained at the Bureau of Standards, Washington; at the Laboratoire Central d'Electricité, Paris; at the Physikalisch-Technische Reichsanstalt, Berlin, and at the National Physical Laboratory, London.

The unit of light at the Bureau of Standards has been maintained through the medium of a series of incandescent electric lamps, the values of which were originally intended to be in agreement with the British unit, being made 100/88 times the Hefner unit.

The unit of light at the Laboratoire Central is the bougie decimale, which is the twentieth part of the standard defined by the International Conference on Units of 1884, and which is taken, in accordance with the experiments of Violle, as 0.104 of the Carcel lamp.

The unit of light at the Physikalisch-Technische Reichsanstalt is that given by the Hefner lamp burning at normal barometric pressure (76 cm.) in an atmosphere containing 8.8 litres of water vapour per cubic metre.

The unit of light at the National Physical Laboratory is that given by the 10 candle power Harcourt pentane lamp prescribed for use by the Metropolitan Gas Referees, burning at normal barometric pressure (76 cm.) in an atmosphere containing 8 litres of water vapour per cubic metre.

As a result of all the comparisons the following relationships are established between the above units:—

The pentane unit has the same value within the errors of experiment as the bougie decimale. It is 1.6 per cent. less than the standard candle of the United States, and 11 per cent. greater than the Hefner unit.

The Bureau of Standards (U.S.A.) proposed to reduce its standard candle by 1.6 per cent. provided that France and Great Britain would unite with the United States in maintaining the common value constant, and with

the approval of other countries would call it the International candle. The National Physical Laboratory, London, and the Laboratoire Central d'Electricité, Paris, have agreed to adopt this proposal in respect to the photometric standardisation which they undertake, and the date agreed upon for the adoption of the common unit and the change of unit in the United States is April 1, 1909.

The following simple relations will therefore hold after that date:—

Proposed New Unit = 1 Pentane Candle.
= 1 Bougie Decimale.
= 1 American Candle.
= 1.11 Hefner Unit
= 0.104 Carcel Unit

Therefore 1 Hefner Unit = 0.90 of the proposed New Unit.

The proposal to call the common unit of light to be maintained jointly by the national standardising laboratories of the United States, France, and Great Britain the "International candle" has been submitted to the International Electrotechnical Commission, and through it to all the countries of the world which are represented on that Commission.

It is hoped that general approval will be secured, and that in the near future the term "International candle" for the new unit will have official international sanction.

PATENTS.

Dehydration of moist materials, more especially peat. Oberbayerische Kokswerke und Fabrik Chemischer Producte A.-G. Fr. Pat. 395,637, Oct. 24, 1908.

THE moist peat, spread in layers, is brought into close contact, but without great pressure, with a layer of sphagnum (bog-moss) or other similar absorbent material, the capillarity of which is greater than that of the material to be dehydrated. The moisture absorbed is afterwards expressed from the layer of sphagnum which is thus rendered fit for use again.—W. H. C.

Nitrogen hydrophosphide; Preparation of — for carburetting alcohol for use in all kinds of explosion motors. A. Barbier. Fr. Pat. 396,366, Jan. 24, 1908.

A solution of white phosphorus in benzol is saturated with a mixture of hydrogen and nitrous oxide and sealed up. After about twelve hours a slight smell of garlic will be observed indicating that the reaction is complete. The liquid so obtained is mixed with alcohol for use in explosion motors.—W. H. C.

Gas generating plants. C. F. Botley, Hastings, and S. Cutler, jun., London. Eng. Pat. 8524, April 16, 1908.

THE claim is for the provision of a spare or reserve generator for a water-gas plant to be used when the ordinary generator has to be thrown out for repairs, in order to avoid the necessity of keeping the whole set idle. One such spare generator is arranged to two units of plant, and can be connected to either set as required.

—W. H. C.

Producer-gas; Method of making —. E. E. Slick. Pittsburg, Pa. U.S. Pat. 921,173, May 11, 1909.

FUEL is burned in an up-draught producer having a vertical front wall and an inclined rear wall, so that the sectional area of the fuel column is greatest at the top of the producer. The coal descends gradually as ashes are removed from a water-trough at the bottom of the producer and fuel is admitted at a regulated rate from a hopper fixed on the front wall of the producer, so that the fresh fuel passes across the top of the fuel bed towards the rear wall. A regulated supply of air under pressure is admitted at the bottom of the fuel column.—A. T. L.

Electric incandescence lamps; Process and apparatus for the reduction of metallic filaments for — J. M. Canello. Fr. Pat. 396,425, Nov. 17, 1908.

The apparatus is for the reduction of metallic filaments by heating electrically in an atmosphere of hydrogen. It comprises a glass bell in which the reduction is effected, a main switch for connecting the circuit to either of three leads supplying current at 300, 500, or 1500 volts, an ampèremeter, a regulating switch for adjusting the voltage by means of a secondary battery, a commutating switch, and a circuit-breaker, the whole being arranged on one base board. The glass bell is held between two horizontal arms, adjustable vertically on a standard. The bell rests on a rubber ring in an insulated plate on the lower arm, and is pressed down to make a tight joint by means of a leaf spring fixed to the upper arm and depressed by a cam. A passage formed in the lower arm is open to the interior of the bell, and is connected to the vacuum pump. The insulated plate carries vertical supports for the filament which also form the leads and one of these supports is hollow and serves for the introduction of hydrogen. The tubes leading to the vacuum pump and to the source of hydrogen are flexible, and may be closed when desired by pressing them against the base board by means of small cams. The circuit-breaker comprises two mercury contacts, and is normally held open by a spring; rubber discs are arranged on the wires which make contact with the mercury, in order to prevent splashing when the switch is suddenly closed. In carrying out the process of reduction, the bell is filled with hydrogen, and the filament brought to incandescence. The bell is then removed, and the filament is given the desired elongated or V-shape by means of a small pivoted weight, carried on one of the filament supports and moved by a magnet. The filament is again heated in hydrogen, the voltage being regulated according to its resistance. To prevent distortion of the filament, a strong permanent magnet is placed beneath the bell to neutralise the earth's field, and if necessary the current reversed by means of the commutator.—A. T. L.

Electric incandescence lamps; Process for preventing the formation of cavities in filaments for — in their manufacture from colloidal filaments. H. Kuzel. Fr. Pat. 396,899, Nov. 30, 1908. Under Int. Conv., Oct. 15, 1908.

FILAMENTS made from colloidal metals by the processes described in Fr. Pat. 359,025 of 1905 and in the second, third, and fourth additions thereto (this J., 1906, 308, 384, 1085; 1907, 919), are liable to contain small or elongated cavities, formed during the rapid shrinkage which occurs when the colloidal filament is heated by the passage of a current. According to this invention the formation of these cavities is prevented by heating the colloidal filaments in a non-oxidising atmosphere at a pressure not exceeding 150 mm. of mercury, and preferably below 40 mm., instead of at atmospheric or slightly reduced pressure. In carrying out the process, a current of gas at low pressure is passed through the vessel in which the filaments are heated, and this vessel is in constant communication with the vacuum pump. In order to carry away the gases liberated from the filaments, and to prevent any rise of pressure due to heating, the gases used consist of a mixture of an inert gas and a reducing gas, for example, a mixture of 80 per cent. nitrogen and 20 per cent. of hydrogen, so that any air leaking into the vessel may not attack the filaments. The filaments are preferably kept under tension during the heating. The process is specially advantageous when the colloidal filaments are prepared in the manner described in Fr. Pat. 371,799 of 1906 (this J., 1907, 434). —A. T. L.

Fuel for internal combustion engines of the reciprocating type; Manufacture of — S. Barth. Düsseldorf-Obercassel, Germany. Eng. Pat. 19,928, Sept. 22, 1908. Under Int. Conv., Aug. 6, 1908.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Natural gas and white petroleum at Baku. J. Gasbelencht., 1909, 52, 435.

At Surachany and Amiradschan in the Baku oil-field, there are occurrences of natural gas. The gas has been used for a long time on a small scale by the natives as fuel for burning lime, and more recently on a larger scale in the petroleum distilling plants. Such a large supply of gas was opened up in the Surachany plain in 1903, that it became possible to use it as fuel in the adjacent Balachany oil-field as well as in the district of its origin. The use of natural gas as fuel at Baku is of considerable importance, for in this oil-field 15 per cent. of the total production of crude oil are used in producing power for boring and transporting purposes; moreover the yield of crude oil is steadily falling and the price rising. The amounts of gas obtained and used as fuel for the past four years were as follows: 1905, 46.53 million cb. m.; 1906, 96.30; 1907, 117.13; and 1908 (Jan. 1 to June 1), 27.92 million cb. m. About 1037 cb. m. of the gas are equivalent in fuel value to 1 metric ton of crude oil.

The so-called "white" petroleum is obtained in the Sabuntchy district. It has the sp. gr. 0.776–0.788, and is used almost exclusively as an adulterant in the preparation of a duty-free but dangerous illuminant. Its use as an adulterant consists in filtering it through animal charcoal and then adding it to ordinary illuminating oil to the extent of 50 per cent.

In other parts of the Baku oil-field the natural gas is used for firing steam boilers and for driving gas-engines, etc.—A. S.

Petroleum production in California. Board of Trade J., May 20, 1909. [T.R.]

PETROLEUM now ranks first among the mineral products of California, its output surpassing that of gold for the first time last year. During 1908 there were remarkable developments, and many new discoveries were made in different parts of the State. Probably the most important one was in northern Santa Barbara County, where several producing wells have been opened, while work is in progress on many others with indications that oil will be found in paying quantities. The Santa Marina district yielded only 99,000 barrels (of 42 gallons) of oil in 1902, while last year 10,000,000 barrels were obtained there. In Contra Costa County, not far from Antioch, it is reported

that oil of high quality has been found. Oil drillers have been at work for some years in that section, but the output has not yet reached commercial proportions. Important discoveries were also made during 1908 in Fresno County. In San Joaquin County there have been some indications of oil in paying quantities. In the Livermore foothills a good grade of oil, with an asphaltum base, has been found at a depth of about 1000 feet.

Mineral lubricating oils: New values in the analysis of — R. Kissling. Chem.-Zeit., 1909, 33, 521–522.

In determining the "coke value" of mineral oils (this J., 1908, 1053; 1909, 84) it is essential to wash the coke-like substances free from alkali by means of hot water, or the results will be too high. This direction was omitted in the previous communications. It has been urged against the author's method that the values obtained with a given oil may vary very widely at different times owing to unavoidable irregularities in the distillation and refining processes. In reply to this the author gives results obtained with 4 samples of the same oils taken from the works at intervals of several months. In the case of a Pennsylvanian machine oil the tar value varied from 0.11 to 0.12; the tar-forming value from 0.52 to 0.57; and the coke-forming value from 0.31 to 0.40. The results obtained with a heavy Russian machine oil were equally concordant, but greater deviations were observed in the results given by another oil of the same kind (tar value, 0.18 to 0.22; tar forming value, 0.49 to 0.63; and coke-forming value, 0.22 to 0.47). Such variations, however, are not great enough to vitiate the method, and in any case it is open to manufacturers to fix limits for the respective values.—C. A. M.

PATENTS.

Calcination, carbonisation, or distillation of mineral or organic materials. Pagès, Camus, et Cie. and P. Bardy. Fr. Pat. 396,623, Jan. 31, 1908.

In those processes in which a gas is circulated through the retort to facilitate the evolution of vapours and gases from the heated material, an unexpected decomposition may sometimes arise owing to the unsuitable nature of the gases used. To avoid this difficulty the gas evolved during the process is collected in a gas holder and used for circulating through the retort after being superheated to the requisite temperature. The materials may be previously heated to nearly the temperature of reaction by circulating other gases through them, e.g., waste furnace gases. By passing the gas from the holder through the residue in the retort before the former enters the superheater, the residue is cooled and the heat contained in it recovered.—W. H. C.

Distillation of industrial fuels: Process of — M. Ferrari, J. Robert, and E. A. Mégret. Fr. Pat. 396,738, Feb. 1, 1908.

The process consists in carrying off the volatile products from the distillation of wood, peat, coal, or other fuel by means of a current of gases at a comparatively low temperature (300°–600° C.). The gases may be hydrocarbons, hydrogen, carbon monoxide, inert gases, or steam. In one method of carrying out the process, the heat of the gaseous current causes the distillation and no external heat is supplied, but in other cases, the retort may be heated sufficiently to make good the loss by radiation, or if necessary, distillation may be effected by external heat.

—A. T. L.

[Mineral] Oil: Means for reducing the freezing-point of — W. R. Whitney, Schenectady, N.Y., Assignor to General Electric Co., New York. U.S. Pat. 919,506, April 27, 1909.

The claim is for the preparation of a low freezing-point insulating fluid formed by adding a hydrocarbon containing a substituted halogen atom, e.g., benzyl chloride, to a high flash-point mineral oil.—W. H. C.

Porcelain mould for paraffin candles. Fr. Pat. 396,744. See XII.

IV.—COLOURING MATTERS AND DYESTUFFS.

Fat dyestuffs: Action of Grignard's reagent on — Part I. Indigo. F. Sachs and H. Kantorowicz. Ber 1909, 42, 1565–1576.

The authors find that when Indigo is added to an ethereal solution of Grignard's reagent, it dissolves with an intense brownish-yellow coloration and heat is generated. When magnesium-phenyl bromide is used, two substances are formed, namely an orange substance soluble in alcohol and a small amount of a colourless acid. The constitution of these substances has not yet been definitely settled, but it is considered that the most probable formula for the principal (orange) substance is

The Grignard reagents employed were ethyl-, methyl-, propyl-, isobutyl-, isomyl-, phenyl- and *p*-tolyl-magnesium bromides and benzyl-magnesium chloride. The product obtained varied in colour from orange to red and resembled that described above. The authors state also that flavanthrene and Thioindigo react with the reagent and they are engaged in the study of these reactions.

—J. C. C.

Naphthol Yellow S. H. Finger. J. prakt. Chem., 1909, 79, 441–445.

By reducing Naphthol Yellow S with stannous chloride and hydrochloric acid, Lauterbach obtained a nitro aminonaphtholsulphonic acid of which an isomeride is produced when the reduction is effected by means of alkali sulphide. As the latter acid forms azo-dyestuff which can be chromed on the fibre, its constitution has been supposed to be OH : NH₂ : NO₂ : SO₃H = 1 : 2 : 4 : 7 whilst the isomeride acid was assigned the formula OH : NO₂ : NH₂ : SO₃H = 1 : 2 : 4 : 7. The author now brings forward evidence to show that these suppositions are correct.

When Lauterbach's acid is diazotised with amyl nitrite it yields a yellow crystalline diazonium compound, which on boiling with alcohol and copper powder, yields 2-nitro-1-naphthol-7-sulphonic acid, forming small, lemon-yellow needles. On reduction with stannous chloride and hydrochloric acid, this gives 2-amino-1-naphthol-7-sulphonic acid, which, in alkaline solution, becomes dark green on exposure to the air. On condensation with nitrosodimethyl-*m*-aminophenol hydrochloride, it yields an oxazine dyestuff which dyes wool intensely blue from an acid bath.—J. C. C.

Safranine: Some derivatives of — Sealed packet No. 937 (deposited Dec. 14, 1896) by C. Gassmann and Report on same by E. Noelting. Bull. Soc. Ind. Mulhouse, 1909, 79, 84–88.

By the combination of diazotised safranines with phenol-carboxylic acids, the author has obtained a series of blue-violet to blue-black dyestuffs which can be printed with chromium acetate. The dyestuff produced from diazosafranine and salicylic acid has probably the constitution,

and forms small brilliant crystals with a greenish reflex. The dyestuff prepared from tolusafraanine and salicylic acid is the reddest of the series and those from the same acid and phenosafranine, Fuchsia, Clematine, and Girofle increase in blueness in the order mentioned. Dyestuffs prepared from ortho- and meta-cresotinic acids are greener, those from α -hydroxynaphthoic acid are deep blue and those from β -hydroxynaphthoic acid are blue-black but are difficult to fix. All the dyestuffs can be

applied by means of tannin, giving redder and duller shades. The indamines and rubramines also give dyestuffs of this series.

Noelting reports on the above to the effect that the dyestuffs are new: in a review of the patents for allied dyestuffs he points out that the use of phenolcarboxylic acids has not been claimed.—J. C. C.

Dyestuffs of the Induline series; Note on the formation of —. Sealed packet No. 938 (deposited Dec. 14, 1896) by C. Gassmann, and Report on same by E. Noelting. Bull. Soc. Ind. Mulhouse, 1909, 79, 89–90.

The author finds that when the products of oxidation of primary amines, such as Aniline Black, react with aniline and its hydrochloride, Induline Blues are obtained. With α -naphthylamine, dyestuffs are produced which are probably identical with rosinduline and its phenyl derivative. The products of oxidation of α -naphthylamine when heated with α -naphthylamine in acetic acid solution give Magdala Red. Diamines such as *p*-phenylenediamine and Aniline Black furnish blue-violet to Indigo-blue dyestuffs fixed by tannin and tartar emetic and, in the case of the product of oxidation of α -naphthylamine, a red violet which is fixed by a tannin mordant. Noelting reports that Nietzki has already studied the dyestuff produced by the action of aniline on Aniline Black, of which the formula is $C_{26}H_{29}N_5$, but he is of the opinion that the other dyestuffs described by Gassmann are new.—J. C. C.

Carminic acid. O. Dimroth. Ber., 1909, 42, 1611–1627.

By oxidising carminic acid with potassium permanganate in sulphuric acid solution at 0° C. (in which operation 7–8 equivalents of oxygen are required), the author has isolated an acid of the constitution:

to which, from its close resemblance to isonaphthazarin, he assigns the name carminazarin. The substance forms garnet red-needles containing 4 mols. of water and dissolves in boiling water with a yellowish-red colour. From carminazarin, by oxidation of the alkaline solution with oxygen, is produced cresotinglyoxyldicarboxylic acid, which on warming with sulphuric acid loses carbon monoxide and forms cochenillic acid, previously obtained by Liebermann and Voswinkel by oxidising carminic acid with potassium permanganate in alkaline solution. In the above oxidation the carminazarin is not formed at once but an intermediate unstable carboxylic acid is first produced which, on warming the solution, loses carbon dioxide with production of carminazarin. From these facts the author deduces that carminic acid is to be regarded as a carminazarin in which the residue, $\frac{1}{2}O_7$, replaces a hydroxyl group thus:

It is seen therefore that, in opposition to the view hitherto generally held that carminic acid possesses a symmetrical structure, it really consists of the fusion of two entirely different groups of which the one is a substituted naphthoquinone and the other must belong to the aliphatic or hydroaromatic series. The latter group has still to be investigated.—J. C. C.

PATENTS.

Brominated indigo sulphide and process of making same. E. Kraus, Frankfurt-on-the-Maine, Germany, Assignor to Cassella Color Co., New York. U.S. Pat. 920,156, May 4, 1909.

Indigo is heated in the presence of suitable diluting agents with sulphur and bromine. The product is a

dark blue powder almost insoluble in alcohol, benzol, and chloroform, but soluble in boiling nitrobenzene and naphthalene. It dyes from a hydrosulphite vat in clear blue shades.—P. F. C.

Basic dyestuffs; Production of —. Farbenfabr. vorm. F. Bayer und Co. First Addition, dated Nov. 23, 1908, to Fr. Pat. 395,793, Oct. 29, 1908. Under Int. Conv., Mar. 7, 1908.

DYESTUFFS similar to those described in the chief patent (this J., 1909, 469) are prepared by condensing aldehydes of the general formula,

(Alk = alkyl; Ar = aryl),

and their oximes or hydrazones with dihydroindole or phenmorpholine or their substitution products, or by condensing with secondary aromatic amines such aldehydes or oximes or hydrazones of the above formula in which

represents the residue of the dihydroindole or phenmorpholine or their substitution products. Further, dyestuffs are also obtained by treating the pyridine dyestuffs described in Ger. Pat. 155,782, June 3, 1903, with such secondary amines as are more strongly basic than the primary or secondary amines of which the residues are contained in the dyestuffs referred to. Example: A mixture of 187 parts of the aldehyde of the formula,

500 parts of alcohol, 200 parts of 30 per cent. acetic acid, and 133 parts of dihydro- α -methylindole are heated in an apparatus fitted with a reflux condenser for 4 hours on the water-bath until the colour of the mass does not change further. The alcohol is distilled off and the remainder poured into water containing hydrochloric acid and salt. The dyestuff is precipitated in the form of microscopic red needles which dye tannin-mordanted cotton in blue-scarlet shades fast to washing and light. The same product is obtained when an alcoholic solution of one molecule of the aldehyde or its oxime or phenylhydrazone and one molecule of dihydromethylindole is kept for several hours. Blue dyestuffs are obtained by employing substituted derivatives of the above aldehyde. Further the dyestuff mentioned in example 1 of the principal patent can be obtained by heating 4.5 kilos. of the dyestuff described in example 4 of Ger. Pat. 155,782 (from sulphanilic acid and cyanopyridinium bromide) with 2.7 kilos. of dihydro- α -methylindole and acetic acid in alcoholic solution. By heating 4 kilos. of the dyestuff described in the German patent (example 2: from cyanopyridinium bromide and monomethylaniline) with 1.4 kilos. of tetrahydroquinoline, a dyestuff is obtained which gives orange shades on tannin-mordanted cotton.—J. C. C.

Monoczo dyestuff; Production of a new —. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 396,381, Nov. 16, 1908. Under Int. Conv., Feb. 24, 1908.

SEE U.S. Pat. 912,356 of 1909; this J., 1909, 304. The dyestuff is prepared by combining diazotised 1,8-amino-naphtholsulphurous ether with 1,8-dihydroxynaphthalene-4-sulphonic acid, and subsequently eliminating the SO_2H group.—T. F. B.

Gallocyanine series; Production of new dyestuffs of the —. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 396,564, Nov. 20, 1908. Under Int. Conv., Feb. 28, 1908.

THE condensation of gallocyanines with aromatic amines, described in Fr. Pat. 378,923 of June 17, 1907 (this J., 1907, 1194) as being effected in the presence of aromatic nitro-hydrocarbons, is very conveniently carried out in the cold by the aid of oxygen, air or other mixtures of gases containing oxygen, preferably with the addition of a catalyst such as manganese, iron or vanadium salts. When gallocyanines derived from gallic acid have been

used, the product of condensation loses carbon dioxide when heated and the residue can readily be sulphonated, whereby dyestuffs are obtained which are purer and faster to chlorine than those described in Fr. Pat. 201,465, Oct. 21, 1889. Example: A mixture of 300 parts of aniline and 50 parts of the galloyaniline prepared from nitrosodimethylaniline and gallic acid is thoroughly stirred and a current of air introduced. After the condensation is finished, the mass is heated to about 100° C. and the resulting dyestuff is isolated and added (50 parts) at 10–15° C. to 200 parts of fuming sulphuric acid (25 per cent. of sulphur trioxide) or ordinary sulphuric acid. The mixture is warmed to 30–40° C. until a sample dissolves in sodium carbonate, and is then poured into water and the precipitated sulphonic acid converted into the ammonium salt. It dyes chrome-mordanted cotton in greenish-blue shades.—J. C. C.

Azo-dyestuffs dying on a mordant; Production of —. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 396,833, Nov. 27, 1908. Under Int. Conv., May 29, 1908.

THE azo-dyestuffs prepared by combining the diazo-compounds of derivatives of 4-nitro-2-aminophenol containing a nitro-group or a halogen atom in position 6, with *p*-chlorophenol or its homologues, can be dyed in one bath with the addition of potassium bichromate. They can also be used to dye wool previously mordanted, or the wool may be chromed after dyeing. Brown shades are produced which are very stable towards light. Example: 200 parts of picramic acid are diazotised and combined with 150.5 parts of *p*-chlorophenol (sodium salt) in the presence of 200 parts of sodium carbonate. The dyestuff is isolated in the usual manner.—J. C. C.

Azo-dyestuffs; Production of new —. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 396,949, Dec. 1, 1908. Under Int. Conv., Mar. 2, 1908.

THE azo-dyestuffs prepared by combining diazotised *p*-nitraniline-*o*-sulphonic acid with β -naphthylamine or 2-amino-8-naphthol or their derivatives in acid solution dye wool from an acid bath in violet-red to blue or black shades which are fast to washing and light. The combination with β -naphthylamine is carried out in acetic acid solution and in the case of the aminonaphthol the diazo-compound is first salted out and then combined in hydrochloric acid solution.—J. C. C.

Vat dyestuffs; Production of —. Badische Anilin und Soda Fabrik. Fr. Pat. 396,583, Nov. 21, 1908. Under Int. Conv., Oct. 2, 1908.

By condensing 1-aminoanthraquinones with halogenated benzanthrone, imino-compounds, termed benzanthranyl-1-aminoanthraquinones, are produced which, when treated with condensing agents, furnish new vat dyestuffs of which the constitution is represented by the formula:—

Examples: A mixture of 6 kilos. of benzanthranyl-1-aminoanthraquinone and 40 kilos. of potassium hydroxide is heated slowly to 240°–245° C. and maintained at this temperature for 15 minutes. After cooling, the mass is boiled with water and the dyestuff is precipitated with a current of air. It forms a greenish-black powder and with alkaline hydrosulphite gives a blue-violet vat from which vegetable fibres are dyed in violet-blue shades becoming green on washing and drying. The condensation may also be effected with alcoholic potash at 155°–160° C. A derivative of this dyestuff can be prepared by condensing the imine by means of sodium ethoxide in the presence of aniline. The dyestuff produced by condensing benzanthranyl-1-amino-7-hydroxyanthraquinone by means of

alcoholic potash gives a violet-blue vat (with alkaline hydrosulphite) from which vegetable fibres are dyed the same colour, becoming bluish-green on washing and drying.—J. C. C.

Indigo dyestuffs; Preparation of leuco-derivatives of —. Badische Anilin und Soda Fabrik. Fr. Pat. 396,794, Nov. 26, 1908. Under Int. Conv., Oct. 14, 1908.

THE difficulties met with in maintaining the cold indigo vat may be overcome by mixing the leuco-compound with molasses, syrup, or glycerin and inorganic reducing agents such as zinc dust, stannous chloride, stannous oxide, etc. Example: 667 kilos. of a paste containing 75 per cent. of indigo white are mixed with 283 kilos. of glycerin and 50 kilos. of zinc dust. A viscous paste is obtained which even in hot climates does not require the addition of aids to fermentation.—J. C. C.

[Azo] Dyestuffs; Manufacture of new —. Farbwerke vorm. Meister, Lucius, und Brining, Höchst on Maine, Germany. Eng. Pat. 3602, Feb. 13, 1909. Under Int. Conv., March 28, 1908.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Wool fibre; Effect of various mordants and dyestuffs upon —. A. Kertesz. Färber-Zeit., 1909, 20, 137–140.

THE results of an earlier investigation upon this subject indicated that the strength and elasticity of the wool fibre may increase during treatment, and although the general character of the wool cannot be said to improve, the results of the dynamometric tests are so regular that (whether they are better or worse than those given by the original wool) some value must be attached to them. In determining the general character of the wool fibre, its shrinking or milling capacity must be considered as well as its strength and elasticity. The results of the trials are tabulated and from these it is seen that untreated wool mills better than that which has been treated in a hot bath of acid sodium sulphate, and the addition of potassium bichromate to this bath lowers the milling capacity still further, the loss depending upon the proportion of bichromate added. As regards the strength and elasticity before and after milling, and the degree of shrinkage, it is found that wool which has been treated with hot distilled water loses about 7 per cent. in strength compared with untreated wool. The elasticity increases

by about 18 per cent., but after milling it is some 7 per cent. less than that of the untreated milled wool, the milling power of the latter being also better. Both strength and elasticity are improved by treating with acid sodium sulphate, but after milling, the figures are almost identical with those obtained with wool which has been boiled with water only, but the milling power has been still further diminished. Treatment with formic acid increases the strength and elasticity of unmilled wool and after milling, the figures are still slightly higher than those with acid sodium sulphate though the milling power is not quite so good. An "afterchrome" treatment of wool prepared with acid sodium sulphate increases both the strength and elasticity, and these do not suffer so much in milling. Formic acid apparently affects the milling power more than does acid sodium sulphate. Mordanting with bichromate, and tartaric or formic acid, or with chromium fluoride lowers both the strength and elasticity compared with the above methods of treatment, but the milling power is slightly better except in the case of the fluoride treatment. Treatment with chlorine diminishes both strength and elasticity, and milling power. Samples of loose wool were treated with the agents above mentioned or were dyed with mordant dyestuffs or indigo; the wool was then spun under identical conditions and the yarn tested. Compared with untreated wool the loss in strength, elasticity, and milling power was but slight and the author maintains that in general the loss is due to the mechanical treatment, and not to any effect of the mordant or dyestuff. —F. M.

Dyeing; Influence of the colloidal state on — L. Vignon. Compt. rend., 1909, 148, 1195—1197.

THE author has examined the action of water on jellies made with starch (which may be regarded as a polyalcohol) and gelatin (which belongs to the class of aminoacids) dyed with Rocceline, Magenta, and Congo Red. Each jelly, weighing 105.5 grms., was left in contact with 1 litre of water for 24 hours at the ordinary temperature. The amount of dyestuff which passed into the water was then estimated. It was found that the starch jellies behaved like cotton and those made with gelatin like wool and silk. The experiments show the double influence of molecular attraction, due to the colloidal state, and of the chemical constitution of the ellies, in the dyeings obtained. —J. C. C.

White reserve with red prussiate for Indanthrene dyestuffs in association with Aniline Black printing. Sealed packet No. 1493 (deposited Aug. 23, 1904) by C. Raczkowski, and Report on same by M. Battagay. Bull. Soc. Ind. Mulhouse, 1909, 79, 91—92.

ANILINE Black or Diphenylamine Black is printed with a reserve composed of 250 parts of potassium ferricyanide and 750 parts of gum and kaolin. After drying, the fabric is printed with Indanthrene Blue colour paste containing tartaric acid, tin salt, and ferrous sulphate together with a thickening of starch and tragacanth, and steamed. In the case of Aniline Black the fabric is steamed before the second printing to develop the black. The material is finally passed through sodium carbonate solution (20° B.) at 75° C. in presence of manganese dioxide, then washed in sulphuric acid (40° B.) and soaped at 75° C. for some minutes. The process can also be applied to the green produced with a mixture of 6 parts of Indanthrene and 5 parts of Flavanthrene.

Battagay reports on the above to the effect that he has confirmed the results described and they are satisfactory provided the shades are not too dark. He considers that the process is new. —J. C. C.

PATENTS

Elastic and supple material [artificial horsehair], and method of manufacturing the same. P. Brosse, Paris. Eng. Pat. 24,110, Nov. 10, 1908.

100 KILOS. of glue are dissolved in 100 litres of water, and about 10 kilos. of glycerin are added, followed by about 5 kilos. of formaldehyde of 90 per cent. strength,

or, alternatively, 10 kilos. of alum. The pasty mass is then forced through very small holes, and passes out in the form of crisp or curly threads, resembling horsehair in appearance. (Reference is directed to Eng. Pat. 15,522, of 1894.) —E. W. L.

Fibrous plants (espa to and others); Treatment of — with an electrolytic recuperating apparatus to obtain textile fibres and paper pulp. F. E. M. Dubrot. Fr. Pat. 396,647, Nov. 14, 1908.

THIS apparatus consists of a vat which is placed in connection with a circulating pump. The inner walls of the vat form the cathode of an electrolytic system whilst the anode consists of a slab of a conducting and unoxidisable substance suspended inside the vat from a bell-shaped support of an inactive and insulating material. The material to be treated is put into the vat together with a suitable electrolyte and a current is passed through the system. The gases liberated at the anode ascend into the bell from which the anode hangs, and are led away through an exit pipe. The electrolyte is kept in constant circulation by means of the pump. —P. F. C.

Artificial silk, etc.; Apparatus and process for the recovery of ether and alcohol from sulphuric acid employed in the manufacture of —. Crépelle-Fontaine. Fr. Pat. 396,664, Feb. 1, 1908, and First Addition thereto, dated July 9, 1908.

THE aqueous alcohol and acid flow from suitably arranged vessels into the top of a distilling column, in the base of which is a vaporiser and which is fitted in the usual manner with distribution plates. The temperature and pressure may be regulated and the vapours of the ether and alcohol after passing through a saturator, in which they are washed by means of a solution of soda, are condensed in a cooling apparatus. The temperature and pressure are regulated automatically, as is also the rate of flow of the liquors into the distilling column. Before entering the column the liquids are slightly warmed, and it is possible to separate the ether and alcohol fractionally. —F. M.

Fibroin from silk; Process for obtaining —. C. D. Baumann and G. G. Diesser. Fr. Pat. 396,305, Nov. 6, 1908. Under Int. Conv., Dec. 21, 1907.

THE solution of fibroin in the usual acid or alkaline solvents is accompanied by a certain amount of decomposition, and the industrial application of such solutions has not hitherto been successful. It is now found that formic acid is a very suitable solvent: it dissolves freshly spun silk readily in the cold, and although ordinary raw silk (grège) dissolves much more slowly, even this is dissolved on heating. From the solution, films may be obtained, or threads which are almost as strong as those from boiled-off silk and possess the same properties as the latter. The solubility of fibroin in formic acid may be applied in the production of thin films (for insulating, etc.) or rendering woven fabrics impermeable to air and water. —F. M.

Washing machines; Rotary —. Entwistle and Kenyon, Ltd., and R. Bradley, Accrington, Lancs. Eng. Pat. 391, Jan. 7, 1909.

THE machine comprises a perforated drum or wince revolving within a fixed vessel holding the liquid, the drum being provided with a removable midfeather or partition. Various arrangements are described for securing the midfeather in position. —B. N.

Printing rollers; Process for preparing —. Weaver Print Co. Fr. Pat. 396,332, Nov. 14, 1908.

AN inclined plane engraved in relief with the required design is coated with an acid reserve and the plain roller is rolled along the coated surface, the reserve being transferred to the roller, which is then completed by the usual engraving process. To ensure the design being transferred to the roller without a break, the parts of the engraving at each extremity of the plane are made to correspond exactly, the engraved part of the plane is slightly longer than the periphery of the roller, and the latter is made to give

slightly more than one complete turn. By a rack and pinion arrangement, the speed of the roller as it rolls down the coated plane can be accelerated or retarded, so that, with practice, the operator can make sure that the overlapping ends of the design are transferred to the roller exactly over one another. The right intensity is given to these double impressions by a mechanical arrangement which relieves the weight of the roller at either end of the plane.—H. P. P.

Printing on textile fibres; Process of —. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 396,983, Nov. 11, 1908. Under Int. Conv., Dec. 2, 1907.

DYE-STUFFS of the thiazine and oxazine classes, with the exception of those of the galloxyamine series, can be fixed upon the fibre by printing with a mixture containing their leuco-compounds, a mordant, and a suitable thickening, and afterwards steaming for 2–5 minutes in a Mather-Platt apparatus. Example: A printing colour is prepared containing 21 parts of a solution of the leuco-compound of Methylene Blue BB obtained by reducing 3.3 parts of the dyestuff with hydrosulphite, 63 parts of water, 24 parts of acetic acid (30 per cent.), 200 parts of starch-tragacanth thickening, 20 parts of a solution of tannic and acetic acids (1:1), and 2 parts of Rongalite C. The material is printed with this colour, steamed for 2 minutes, and finally passed through a solution of tartar emetic.—P. F. C.

Colouring superficially, artificial or natural bodies such as fabrics, leather, artificial leather and analogous substances; Process for —. B. Polack Akt.-Ges. Fr. Pat. 396,299, Oct. 31, 1908.

THE colouring matter is incorporated with a layer of fibres or with a fabric which is afterwards fastened to the outside of the material to be coloured. This can be effected either by adding the colouring matter to the size which is employed to make the fabric adhere to the material, or by first colouring the fabric and afterwards fastening it to the material.—P. F. C.

Lustreing and finishing silk filaments; Apparatus for —. E. Pohl, Paterson, N.J. U.S. Pat. 920,775, May 4, 1909.

THE filaments are first passed through a tank containing a finishing solution and are afterwards led over a roller and across a heated contact surface which may be stationary or movable. The apparatus is also provided with devices for cleaning the roller and contact surface whilst the filaments are passing over them.—P. F. C.

Silk thread finishing machine. E. Pohl, New York. U.S. Pat. 920,776, May 4, 1909.

AFTER finishing and lustreing, the filaments are gathered together in parallel to form a single thread which is passed over drying, ironing, and polishing devices. The machine is also provided with a device for taking up the thread which is automatically stopped by the breaking of any of the individual filaments. This device comprises a bobbin, rotated by friction, which can be thrown out of action by a stop-lever. This lever is normally out of engagement with the bobbin, but can be thrown into action by the fall of any of a number of guiding levers which are so supported by the individual filaments that the breakage of one filament causes the fall of one guiding lever.—P. F. C.

Waxed cloth and paper, and their substitutes; Process of manufacture of —. Gebr. Siebert. Fr. Pat. 396,467, Nov. 19, 1908.

THE usual process of manufacture, which consists in covering the material with successive layers of linseed oil (drying after each application), embossing as required, and finally varnishing, requires a great deal of time and the claim in the present patent is for the employment of a solution of acetylcellulose. A single coat is sufficient and the film which remains, being transparent, the material may be suitably dyed, printed, or embossed beforehand without the effect suffering in the least.—F. M.

Drying chamber [for cloth, etc.] heated by warm air, by combined radiation and convection, with recovery of the heat without admixture with the saturated air, with methodical and progressive drying. C. H. Vandamme Fr. Pat. 395,802, Oct. 30, 1908.

THE web of cloth or other material to be dried is caused to pass over rollers through the chambers into which the apparatus is divided and which are provided with gilled radiating pipes heated by steam. Fresh air is blown into the apparatus by a fan, after being heated by the exhaust air in a counter-current apparatus having thin walls. The air passes through the dryer in the opposite direction to that taken by the material being dried and is withdrawn from the apparatus by fans and delivered into the counter-current apparatus.—W. H. C.

Straw of flax or other plants; Chemical process for the treatment of the —. A. M. de M. de Ballore, Assignor to Soc. Anon. pour la Fabr. des Pâtes à Papier de Lir et Succédanés, Tunis, Africa. U.S. Pat. 921,502, May 11, 1909.

VII.—ACIDS, ALKALIS, SALTS, AND NON-METALLIC ELEMENTS.

Sodium nitrate; Consumption of — in the United States. C. E. Munroe. J. Ind. and Eng. Chem., 1909, 1, 297–299.

THE consumption of sodium nitrate in the United States in 1900 and 1905 is shown in the following tables, the figures being classified (1), according to the industry in which the nitrate was used both directly and indirectly, and (2), according to the products in the manufacture of which sodium nitrate was used directly. For example, sodium nitrate is used in the manufacture of sulphuric acid in the fertiliser industry, as well as a direct component of fertilisers.

(1). Consumption of sodium nitrate by establishment classes.

Class.	1900.	1905.
	Short tons.	Short tons.
Fertiliser industry	19,518	42,213
Dyestuffs industry	223	261
General chemicals industry	35,900	38,043
Glass industry	10,770	11,915
Explosives industry	88,024	133,034
Sulphuric, nitric and mixed acids industry	27,406	29,301

(2). Consumption of sodium nitrate classified according to products in the manufacture of which it is directly used.

Products.	1900.	1905.
	Short tons.	Short tons.
Compound fertilisers	13,058	34,705
Dyestuffs	223	261
General chemicals	30,287	31,324
Glass	10,770	11,915
Explosives	76,696	100,985
Nitric acid	30,213	50,301
Saltpetre	5,703	6,724
Sulphuric acid	15,481	18,467

If the totals shown in the above tables, 182,431 and 54,772 short tons respectively, be deducted from the quantities available in the corresponding periods as shown by the import tables, it is found that there are 23,926 short tons in 1900 and 67,937 short tons in 1905, which may be regarded as the quantities used in smelting, as a metallurgical flux, in pickling, in the manufacture of minor chemicals, etc. The relatively small consumption of sodium nitrate in the fertilizer industry is accounted for by the extensive use of other nitrogenous substances in the United States. For instance, in the census year 1905, there were used as fertilisers, 1,540 tons of ammonium sulphate, "923,305 thousand lb," 125,888 tons of "ammoniates," 1160 tons of salt-stre, £495,093 worth of cottonseed meal, and £1,061,281 worth of bones, tankage, and offal. The chief factors which tend to prevent increase in the consumption of sodium nitrate in the United States are:—(1). Increased production of ammonium sulphate owing to more extended use of by-product ovens for coking coal. In the census year 1905, only 3,317,585 tons of coke out of a total production of 37,376,251 tons, were produced in by-product ovens. (2). Substitution of the contact process for the lead chamber process in the manufacture of sulphuric acid. (3). The introduction of calcium cyanamide as a fertiliser. (4). The manufacture of nitrates from atmospheric nitrogen.—A. S.

Nitrate combine; Expiration of the —. Oil, Paint, and Drug Rep., May 17, 1909. [T.R.]

At a meeting held March 29, 1909, it was definitely decided to discontinue the combination among the Chilean producers of nitrate of soda, for the control of the production and exportation of that article. Forty-one producers, representing seventy-seven "oficinas" (nitrate works), accepted quotas of production aggregating 40,480,000 Spanish quintals of 101.61 pounds each, and forty-six producers, representing seventy-seven oficinas, refused to accept the quotas assigned to them. Those refusing to accept demanded quotas aggregating 10,800,000 quintals more than was proposed to them. As a consequence the rate combination ceased to exist on March 31, 1909. In the future, or until a new combination be formed, there will be unlimited production and exportation by several oficinas. This condition is desired by many of the producers who possess rich deposits and whose cost of production is low, and the general opinion is that the nitrate market will suffer at least only a temporary depression as a result. The "Asociacion Salitrera de propaganda," however, still continues as an advertising medium, and as a statistical department for the industry.

Ferric chloride and potassium ferricyanide; Reaction between —. Y. Kato. Mem. Coll. Sci., Kyoto Univ., 1908, 1, 352—374.

In adding potassium ferricyanide to ferric chloride dissolved in water and in various solutions of other salts, was found that potassium ferricyanide reacts with ferric chloride, not only in concentrated solutions of the latter but also in those of many other salts. Salts of metals having the same valency in solutions of equal concentration have nearly equal capacity for promoting the reaction. The reaction takes place in a more dilute solution of the salts of metals of higher valency than those of salts of metals of lower valency. It is suggested that the precipitation of Prussian blue by the salts plays an important part in the reaction, an opinion which is confirmed by the study of the interaction between ferric nitrate and sulphate and potassium ferricyanide. The explanation that the reaction is caused by the composition of ferric chloride due to a change in the concentration is not considered plausible.—E. F. A.

PATENTS.

Oxides of nitrogen; Recovery of — from air or other gases with which they are mixed. Sir. W. Ramsay. London. Eng. Pat. 26,981 of 1907; date of application, July 3, 1908.

When nitrogen and oxygen unite in an electric furnace, the percentage of oxides of nitrogen in the escaping gases

is so small that when they are absorbed for the production of nitric acid or nitrates, the efficiency of absorption is low. If the percentage is increased, the efficiency of absorption is greatly increased. To achieve this, the mixed gases are liquefied, after having been cooled by the gaseous products of the liquefying apparatus; the products of liquefaction are then subjected to evaporation and rectification to concentrate the oxides of nitrogen; the concentrated liquid obtained is evaporated, and the products passed through water or other suitable liquid or material. A modified method effects the preliminary cooling of the mixed gases to such a degree that the oxides of nitrogen are separated by fractional liquefaction.

—H. H. S.

Nitric acid, free from nitrous compounds and of increased concentration; Production of —. J. J. E. Douzal. Fr. Pat. 396,367, Jan. 24, 1908.

NITROUS gases, before hydration, are cooled to 24° C. and are then treated with a stream of oxygen, rich in ozone, in the presence of a shower of cold water; nitrous acid is thus transformed quantitatively, as produced, into nitric acid, without the formation of nitric oxide, and an acid of a concentration hitherto impossible is obtained.—F. SODN.

Nitrous products [nitric acid and nitrogen peroxide]; Production of — by combustion. Badische Anilin und Soda Fabrik. Fr. Pat. 396,375, Nov. 16, 1908. Under Int. Conv., April 10, 1908.

OXIDES of nitrogen are produced by burning carbon monoxide in an atmosphere containing oxygen and nitrogen under pressure. For the rapid cooling of the products, in order to prevent the decomposition of the oxides of nitrogen, the flame is given a long pointed form and is made to lick the sides of the tube in which it burns, the tip of the flame being directed against a cold surface. Before allowing them to expand, the gases are further cooled, so as to give liquid or solid nitrogen peroxide; or, concentrated nitric acid is prepared directly by the addition of sufficient steam or hydrogen or other combustible to the gases before combustion. The refrigeration may be effected by the expansion of gas already refrigerated, and the heat produced by combustion may be utilised in obtaining the required compression.

—F. SODN.

Hydrofluosilicic acid and fluosilicates; Manufacture of —, principally by utilisation of residues from superphosphate factories. L. Rivière. Second Addition, dated Jan. 29, 1908, to Fr. Pat. 375,989 of May 28, 1906 (this J., 1907, 936; 1908, 281).

THE absorption of the fluorine compounds cannot always be realised in the way indicated in the first addition. The aspirating arrangement must sometimes be replaced by one for pulverising the absorbing solution, the gases being diverted from the chimney into a side channel for treatment. Soluble or insoluble fluosilicates may be made in this manner, but the claim is particularly for the manufacture of the former (those of aluminium, magnesium, zinc, lead, etc.); these are found to replace hydrofluosilicic acid with advantage in the treatment of residual liquids obtained in distilling, soap-making, and wool-washing, and the raw materials of the beetroot industry, also for the purification of saccharine juices and syrups and the precipitation of potash from must.

—F. SONN.

Alkali carbonates; Process of manufacture of —. 1. Rivière. Fr. Pat. 396,448, Nov. 16, 1908.

POTASSIUM fluosilicate is produced, either directly by adding hydrofluosilicic acid or soluble fluosilicates to vineasses, wines, molasses, saccharine juices, or syrups, or by slowly digesting these alcoholic or saccharine liquids on beds of sodium fluosilicate, in order to transform the contained potassium carbonate into potassium fluosilicate, and following this by a second rapid digestion, at an increased temperature, in order to convert the potassium sulphate and chloride present into potassium fluosilicate, the digestions being effected in groups of vessels communicating with each other and arranged

stepwise. Alkali carbonates are then prepared from the fluosilicates by dissociating them at a red heat in a suitable furnace, the fluorides thus obtained being converted into carbonates by double decomposition with chalk, in the presence of water, without heating. The silicon fluoride, also produced, is absorbed by hydrogen fluoride to give hydrofluosilicic acid again, the hydrogen fluoride for this purpose being obtained by decomposition of the calcium fluoride previously formed.—F. SODX.

Sodium carbonate and all grease-removing products with a sodium carbonate basis; Crystallisation of — on sawdust. G. M. J. Dieres-Monplaisir. Fr. Pat. 396,951, Dec. 1, 1908.

THE claim is for a product, capable of removing grease from floors, rubber tyres, and other surfaces, which is prepared by the crystallisation of sodium carbonate, or other cleansing agent with a sodium carbonate basis, on sawdust of any kind. It is used with cold water, the sawdust acting as a scouring agent and retaining the moisture on the surface, if prolonged treatment be desired.—F. SODX.

Zinc oxide; Methods of making —. L. S. Hughes, Assignor to Picher Lead Co., Joplin, Mo. U.S. Pat. 920,336 and 920,337, May 4, 1909.

ZINC sulphide, in a state of fine division, is injected upwards by means of an air jet into a vertical furnace, heated internally by a non-reducing gas flame to a temperature at which the sulphide is roasted to oxide, but cooled sufficiently to avoid injuring the oxide formed. The impurities are allowed to settle from the gases leaving the top of the furnace, and then the zinc oxide is separated from these gases by screening. Zinc oxide is made from zinc carbonate in a similar manner.—F. SODX.

Litharge; Method of manufacturing —. L. S. Hughes, Assignor to Picher Lead Co., Joplin, Mo. U.S. Pat. 920,335, May 4, 1909.

FINELY-DIVIDED lead carbonate is injected upwards into a vertical furnace maintained at an internal temperature sufficient to convert the carbonate into litharge in a substantially non-reducing atmosphere. The litharge is carried out with the gases at the top of the furnace and, after the impurities have settled, is itself separated from the gases. The walls of the furnace are of thin iron and unlined, so that their temperature may be kept below that at which litharge will adhere to them.—F. SODX.

Zinc sulphide; Manufacture of —. Soc. Chim. des Usines du Rhône (formerly Gilliard, P. Monnet, et Cartier) and J. C. A. Meyer. Fr. Pat. 395,541, Nov. 19, 1908. Under Int. Conv., Dec. 3, 1907.

NEARLY all the zinc may be precipitated as sulphide, by means of hydrogen sulphide, from an almost saturated solution of zinc sulphate, or other salt of zinc with a mineral acid, if contact between the gas and solution be intimate and prolonged. This may be done, for example, in the case of a 45 per cent. solution of crystallised zinc sulphate by pulverising it in an atmosphere of hydrogen sulphide and maintaining contact as long as the gas is absorbed. The zinc sulphide is precipitated in a form which is claimed as new, being non-colloidal and readily filtered, and the filtrate may serve for regenerating the zinc solution by neutralising it with an appropriate mineral containing zinc.—F. SODX.

Carbide; Treatment of —. A. R. Frank, Berlin, Germany. U.S. Pat. 920,857, May 4, 1909.

CARBIDE "fines" of a high degree of purity are obtained by comminuting the carbide, at a temperature above the normal, in an atmosphere of nitrogen or other inert gas that will not decompose the carbide.—F. SODX.

Alumina; Process of making —. C. M. Hall, Niagara Falls, N.Y., Assignor to Aluminium Co. of America, New Kensington, Pa. U.S. Pat. 921,699, May 11, 1909.

BAUXITE is heated in admixture with calcium chloride, with or without the addition of common salt, in an

atmosphere containing oxygen or in the presence of steam. The calcium chloride is used in sufficient quantity to combine with the alumina and silica of the bauxite, and to form an insoluble "silicate of alumina-silicate," and the alumina is obtained by the decomposition of the calcium aluminate.—A. T. L.

VIII.—GLASS, POTTERY, AND ENAMELS.

Earthenware glazes; Leadless —. M. Schmidt. Sprechsal. 1909, 42, 284—286.

MANY so-called leadless glazes contain lead. It is difficult to dispense with it on account of the superior appearance and enduring qualities of lead glazes. Borax must be used in leadless glazes to keep the melting-point low, and borax interferes with colours. After various trials which were unsatisfactory owing to the rapid settlement of the glaze in the tub, and to the flaking-off of the raw glaze on the crockery when handled, the author chose a glaze of the molecular formula: $(0.175K_2O, 0.175Na_2O, 0.650CaO, 0.55Al_2O_3, 5SiO_2, 1B_2O_3)$. This glaze was found to be suitable in all respects. It is fired at cone 2, and, if finely ground, comes up at cone 02. The glaze is made from 0.1 equivalent of felspar-sand, 0.25 of washed kaolin and 0.9 of the following frit— $(0.139K_2O, 0.139Na_2O, 0.722CaO, 0.178Al_2O_3, 3.768SiO_2, 1.11B_2O_3)$. The felspar sand has the molecular formula: $(0.5K_2O, 0.5Na_2O, 1.33Al_2O_3, 8.73SiO_2)$, and the kaolin, $Al_2O_3, 3SiO_2, 2H_2O$.—H. H. S.

Enamel; Manufacture of, and influence of clay on —. J. Grünwald. Sprechsal. 1909, 42, 287—289.

THE manufacture of first-class enamels demands the most scrupulous care in every operation. The raw material should be mixed in sufficiently small lots, e.g., about 150 kilos. The mixture is then fired; as it melts, it

separates into two layers, the upper containing the lighter constituents such as borax and alkali. With insufficient stirring, the melted mass would vary in composition and in physical properties. The enamel then goes to the mill. The time of grinding is very important; the blue obtained with cobalt oxide, for example, depends more on prolonged grinding than on the amount of cobalt present. The older the enamel and the more carefully it is cleaned, the better in appearance, the more pliable, and the more profitable it will be. On this account, cleansing apparatus should be in every works, and after the grinding and cleansing, the enamel should be allowed to rest in a scrupulously clean wooden tub for at least 14 days. The author gives the following figures for a good enamel: Melt together 32 kilos. of borax, 5 of tin oxide, 60 of felspar, 20 of cryolite, 1 of calcined sodium carbonate, 3 of saltpetre, 2.5 of clay, 0.2 of calcined magnesia, and 0.1 of fluorspar. To 100 kilos. of the melted enamel, add in grinding 7 of cleansed clay, 7 of tin oxide, and 0.3 of calcined magnesia. The percentage composition of the finished enamel will be: boric anhydride, 16.13; alumina, 14.25; sodium oxide, 15.88; potassium oxide, 7.37; calcium oxide, 0.05; silica, 31.31; tin oxide, 9.78; magnesia, 0.5; and fluorine, 0.17. An enamel ready for use should contain from 10—18 per cent. of total alumina. The addition of clay in grinding is of fundamental importance. Without it, a finely-ground enamel with 30 per cent. of water would quickly sink, and so make enamelling and transfer-work impossible. The colloidal properties of clay enable the enamel to remain a suspension, even when it is of a creamy consistence. The relative costs of enamel and clay should be considered. As clay is less expensive than enamel, the cheaper enamels might contain 15 per cent. of clay, whereas the better class would contain only 10 per cent. The cheaper enamels would thereby lose in lustre, but gain in opacity. The clay used should not be very "fat"; it should contain 1—55 per cent. of silica, 31—34 of alumina, less than per cent. of iron oxide, and should be quite free from alkali. The clay must not be ignited, as it would thereby lose its characteristic property of holding the enamel in suspension in the "slop." It is important to know the shrinkage of the clay at the temperature of the enamel-urn (850°—950° C.). If after firing, the enamel has cracked, the clay is too "short." Before use, the clay should be stirred in wooden tubs for days, passed through fine sieve, and scrupulously cleansed. For coloured enamels, clays containing iron oxide may be used, as they are cheaper and do not spoil the colours.—H. H. S.

PATENTS.

Glass plates; Process and apparatus for manufacturing — P. T. Sievert, Dresden, Saxony, Eng. Pat. 25,042, Nov. 20, 1908. Under Int. Conv., Nov. 21, 1907.

Rolling glass for forming plates by means of iron rolls. The glass surfaces get a rough hammered appearance. The hammered appearance is due to the sudden and strong absorption of heat from the glass by the thick iron rolls, which causes a shrinkage of the glass skin and great brittleness of the plate. The rough appearance is due to the coarse structure of the cast iron. The inventor therefore introduces between the glass and the rolls, a layer withdrawing very little heat, such as a thin metal plate, or layers of pulp, asbestos, or fibrous material suitably distended in order to prevent combustion. These separating layers may be made in endless bands, and one may serve for several pairs of rolls.—H. H. S.

Kn; Continuous or intermittent — for the burning of refractory or ceramic products. H. Renard, Fr. Pat. 396,911, Nov. 30, 1908.

KILN consisting of two long parallel chambers connected at the ends is provided with a series of fire-bars which extend over the whole bottom of the kiln, the joints between adjacent sections of the fire-bars being transverse to the length of the chambers. The solid fuel burnt is placed on these fire-bars. Even heating is ensured by providing a flue in the roof of the furnace above each section of fire-bars. The hot gases on their way to the chimney from the chambers are forced to pass through serpentine passages

in the masonry of the kiln, and in so doing heat the incoming air, which passes through other similar passages. —A. G. L.

Ceramic, glass, and similar articles; Application of metallic coatings to — H. L. Sulman, H. F. K. Picard, and F. P. Heath, Fr. Pat. 396,531, Nov. 19, 1908. Under Int. Conv., April 1, 1908.

Porcelain mould for candles. Fr. Pat. 396,744. See XII.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Portland cement; The "swelling theory" of — H. Kühl, Tonind. Zeit., 1909, 33, 556—557.

FROM his own experiments (Tonind. Zeit., 33, 465), Schumann thinks that any swelling up of cement particles under the influence of water, must be made obvious in an external increase in volume of the cement paste. The author however considers that the hypothesis proposed by Michaëlis was that only a swelling up of each individual cement grain takes place, in consequence of which the empty spaces between the grains of the mixed cement or mortar mass are filled up. In this way the pore spaces disappear, becoming filled with a gelatinous mass, whilst the mixing water previously contained in the pores is sucked up. The cement grains swollen up into a jelly come into the closest mutual contact, and then under the crystallising action of calcium hydroxide and "internal desiccation" the setting takes place. The mixing water too would dissolve certain constituents of the cement particles, chiefly lime, and the residual bodies would thus acquire a porous structure which would allow them to absorb mixing water. Alite is the most important crystalline constituent of Portland cement clinker, and a certain quantity of it would pass into solution as such, and then, probably be very quickly decomposed, with formation of calcium hydroxide and basic calcium aluminates and silicates. As alite dissolves more easily in water than some of its decomposition products, after a certain time, these less soluble compounds would begin to separate out. In this way the alite in solution would be continuously diminished, and the deficiency would be supplied by fresh quantities passing into solution, which would in turn be decomposed and the products thrown out. Finally the mixing water would become saturated with the easily soluble decomposition products, besides the calcium hydroxide, and these would also begin to separate out. Though little is known of these products, or of their order of separation, they appear to be crystalline in nature. If in the course of the hardening, colloidal substances separate, these would form, by coagulation, a gelatinous mass, though not exactly a swelling-up of the cement in the sense used by Michaëlis. In most of his experiments Michaëlis used concentrated lime water, and as most of the compounds concerned in the reactions are sparingly soluble, the excess of water over cement was not as great as would appear at first sight, and in nearly all cases he found that the resulting products in the process of hardening were very voluminous. If amorphous products are actually formed, these would separate from the solution as a jelly, which would become more and more dense as the hardening process went on, and this would be in agreement with the increasing resistance of the mass, and the decreasing permeability by water which are seen in mortar. The author argues that it is not a swelling-up of an insoluble residual body, but rather the formation of a bulky precipitate, possibly in conjunction with the separation of a gelatinous mass, which forms the actual process in the setting and hardening of cement.—W. C. H.

PATENTS.

Water-, acid-, and alkali-proof articles; Manufacture of — [from wood-pulp]. I. L. Roberts, Lockport, N.Y. U.S. Pat. 921,000, May 11, 1909.

ARTICLES made of woody material are rendered proof against the action of water, acid, and alkali, by heating them in a bath of suitable resistant material under reduced pressure, until the articles are partially carbonised, and also permeated by the bath liquid employed. The articles are left in the bath while the pressure is relieved and the bath allowed to cool.—A. T. L.

Waterproof and fire-, water-, and oil-resistant articles; Manufacture of — from fibrous materials [cellulose]. I. L. Roberts, Lockport, N.Y. U.S. Pat. 921,001 and 921,002, May 11, 1909.

PULPED or fibrous cellulose is formed into articles of the desired shape, and these are rendered waterproof by heating to 240–400° F. for two hours or longer. The articles may then be impregnated with a hot aqueous solution of an alkali silicate in order to render them resistant to fire and to oil or grease.—A. T. L.

Bricks, stones, and other products of hard materials; Manufacture of —. J. J. Loke. Fr. Pat. 396,468, Nov. 19, 1908. Under Int. Conv., Oct. 29, 1908.

TITANIFEROUS iron sand is fused, preferably in an electric furnace of the resistance type, and cast into moulds, very hard and resistant bricks, etc., especially suitable for paving, being obtained. The sand, if poor, may be concentrated, magnetically or otherwise; conversely, silica may be added to a rich sand.—A. G. L.

Mortar and artificial stone made from it; Process of rendering — waterproof. J. Kathé. Fr. Pat. 396,486, Aug. 29, 1908.

MORTAR is rendered waterproof by adding bituminous products (obtained by distillation) mixed with clay. In place of, or together with, the bituminous products, there may be added oils, fats, waxes, resins, or soaps.—A. G. L.

Marble or cement; Process for colouring or artificially veining —. E. G. Prats. Fr. Pat. 396,748, Nov. 13, 1908.

MARBLE or cement is coloured or veined by applying to the whole or part of the surface one or more solutions containing alcohol, acids, or alkalis, and oils, fats, gums, resins, etc., mixed with a colouring matter. The process may be carried out in the cold or with the aid of heat. Thus, marble coated with sulphur and heated, becomes black.—A. G. L.

Artificial and coloured wood; Method for making —. C. Müller. Fr. Pat. 396,912, Nov. 30, 1908.

A PRODUCT named "artifakt" is produced by impregnating sawdust or wood planings with potassium silicate, adding about 10 per cent. of asbestos powder, mixing with magnesium cement and magnesium chloride, and moulding. A colouring matter may be added to the mixture; or else the empty moulds may be lined with a design in one or more colours, and the mixture then introduced.—A. G. L.

Bitumen and other substances; Treatment of — for the manufacture of mortar and concrete used for paving, roads, hydraulic works, tuyères, etc. M. G. C. R. d'Olivier-Mansan. Fr. Pat. 396,981, Nov. 9, 1908. Under Int. Conv., Nov. 12, 1907.

A WATERPROOF and resistant binder is obtained by adding to 30–35 per cent. of melted pitch or bitumen, 60–65 of dried aluminium silicate (clay), 4–5 of calcium sulphate (plaster of Paris), and lastly 0–10 of manganese dioxide. The whole is then heated and stirred for 20–30 minutes at 200–250° C. The hardness and resistance of this so-called "gangue" increase with the proportion of manganese dioxide added, and the duration of the heating. The binder is mixed with the usual aggregate.—A. G. L.

Meadow lime ["Wiesenkalk"]; Process of burning —. Chem. Lab. für Tonindustrie und Tonind.-Zeit. H. Seger und E. Cramer, Ges. m. b. H. Ger. Pat. 209,925, June 1, 1907.

A MIXTURE of meadow lime ["Wiesenkalk"] and peat is formed into heaps, dried, and then burnt either in the heaps or in kilns.—A. S.

Cement-burning apparatus. H. S. Spackman. Ardmore, Pa. U.S. Pat. 920,784, May 4, 1909.

THE lower end of a rotary kiln is surrounded by a substantially air-tight hood. Through the lower part of the hood extends an air-passage provided with a deflecting arch at the upper end so as to direct air into the kiln close to and parallel with the top of the kiln. A gas-burner tube fed with hot gas from a number of contiguous gas-producers projects through the hood below the deflecting arch, and on the ascending side of the kiln axis, an inspection hole provided with a door being provided on the other side. The air delivered into the kiln is heated by passing through a rotary cooler and shoot, through which the burnt clinker is delivered from the kiln.—A. G. L.

Cement [from lime used in sugar purification]; Manufacture of —. R. Tornay-Schosberger. Fr. Pat. 396,600, Nov. 23, 1908.

SILICIOUS materials are added either to the lime used in defecating beet-sugar, or else to the saccharine liquid itself, before or after adding lime. The precipitate produced on carbonation is freed as far as possible from liquor, and burnt to cement. The quantity and kind of silicious material added are chosen so as to yield any desired cement, e.g., Portland cement.—A. G. L.

Concrete and mortar; Process of making waterproof —. P. Mecke. Fr. Pat. 396,694, Nov. 25, 1908.

SEE Ger. Pat. 200,968 of 1908; this J., 1908, 1021.—T.F.B.

X.—METALS AND METALLURGY.

Mineral production of Japan in 1908. Mining World, May 22, 1909. [T.R.]

THE total output of minerals in Japan during 1908 amounted to \$51,614,000 gold in value, a falling off of \$1,799,000, compared with 1907. The production of the principal minerals in 1908 is shown below in quantities (1 momme=58.21 grains; 1 kin=132 lb.; 1 kwamme=8.27 lb.; 1 liquid koku=47.65 gallons):—

Mineral.	Amount.
Gold, momme	795.571
Silver, momme	28,356.05
Copper, kin	67,805.63
Lead, kin	4,899.62
Iron, kwamme	41.60
Coal, kwamme	14,468.66
Mercury, kin	1.15
Petroleum, koku	1,568.38
Sulphur, kin	53,815.07

The total number of mining disasters recorded during last year was 14,749, resulting in 506 people killed and 14,673 injured. Miners in employment at the end of last year number 214,439.

German iron industry; Development of the —. F. Wüst. Metallurgie, 1909, 6, 265–295.

THE production of Bessemer steel commenced in German, in 1861, and by 1867, 73,000 tons were produced, Germany then taking the third position among the steel producing countries. In 1870 Bessemer's patent expired and the German steel production increased rapidly, the increase being somewhat retarded but not stopped by the crisis of 1873. Owing to the more favourable condition with regard to the supplies of suitable ores, the Bessemer process was utilised more largely in England than in

Germany, and still more largely in the United States. In 1879 the Thomas-Gilchrist process was introduced and was immediately adopted in Germany, where by 1879 the production of Thomas steel amounted to million tons. Thomas steel was for a considerable time looked upon with some disfavour in England, and late as 1890 was not allowed in shipbuilding by the British Admiralty and Lloyds. The cost of production of Thomas steel in Germany was considerably less than that of Bessemer steel in England, and Germany became a position not only to supply the whole of the home market, but also to export considerable quantities. In 1903 Germany took second place among the steel-producing countries, displacing England, and has since kept its position. In the author's opinion, however, the development of the Siemens-Martin furnace and its more modern modifications (Bertrand-Thiel and Talbot furnaces) tends to be taken into serious consideration by Germany. Here the Thomas process is still the one most extensively used. Apart from the fact that Martin steel is more valuable than Thomas steel, it is pointed out that the cost of production by the Thomas process is at its lowest point and is likely to rise owing to the increased price of pig-iron. On the other hand the Martin process must be considered as only in the period of development, so that the difference in the costs of production by the two processes should become less and less, until finally the Martin process becomes the cheaper. Curve-diagrams are given showing for England, Germany, the United States, and France, the production of pig-iron and steel, the production of Martin steel, the consumption of pig-iron, the production and consumption of pig-iron per head of population, and the consumption of iron per sq. m. of land, all for the period of 1890—1907, and the estimated future production of pig-iron up to 1920.—A. S.

blast furnace gas engines. Times, Eng. Suppl., May 12, 1909, 17.

The largest plant for the utilisation of blast-furnace gases by gas engines, has just been installed at Barrow. The gases from four blast-furnaces, which have a weekly output of 1200 tons of iron per furnace, have hitherto been used for firing boilers to drive blowing-engines. In the present plant, in addition to furnishing the power required to supply the blast for the furnaces, the gas is used to run electric generators which supply all motor and lighting power required, including that for the fitting shops, furnace hoists, pumps, and hammers. Sufficient gas is left to fire the boilers for driving the wheels of the Bessemer steel producing plant. The gas plant consists of five 1250 b.h.p. gas blowers, one 1250 p.p. generator, and two 750 b.h.p. gas generators. The gas is passed through dust-catchers and washers, the treated gas only containing 0.015 grm. of dust per cu. m. During the first week's run, a saving of 1000 tons of coal effected, which, together with other economies, works out at a saving of about £1000 per week. This proves that large gas engines are practical and economical power sources, especially where fuel is comparatively costly, at Barrow.—F. R.

Cupola gases; Quantity and composition of —. G. Buzek. Stahl. u. Eisen, 1909, 29, 712—714.

The percentage of carbon dioxide in cupola gases does not alone give a correct indication of the completeness of the combustion of the coke. Free oxygen may be present in such quantities that of two different cupola gases, that with the lower percentage of carbon dioxide correspond with a more complete combustion of the coke. The efficiency of the combustion, expressed as the ratio of the percentage of the coke burned to carbon dioxide to the percentage burned to carbon monoxide, can be calculated from the percentages of these gases present in the cupola gases. To ascertain the excess of oxygen, it is necessary to determine also the percentage of oxygen in the gases. An excess of 10 per cent. of oxygen is usually required for the processes of oxidation which occur in the cupola. The paper contains a table giving the calculated volume and composition of the

gases formed from 1 kilo. of coke, assuming different values for the percentage of coke burned to carbon dioxide, and for the excess of air used.—A. T. L.

Cast irons; The nature of —. G. B. Upton. J. of Physical Chem., 1909, 13, 388—416.

THE author's equilibrium diagram of the iron-carbon alloys (this J., 1908, 1114) is stated to give an entirely satisfactory explanation of the constitution of the cast irons. The effect of other elements on the percentage of carbon in cast irons of the eutectic composition or "saturated" cast irons is summarised by the formula: $4.25 - 0.27\text{Si} - 0.32\text{P} - 0.3\text{S} + 0.03\text{Mn}$, and the percentage of graphite that may be expected is the "equivalent total carbon" (total carbon $+ 0.45\text{Si} + 0.1\text{P} + 0.05\text{S} - 0.03\text{Mn}$) minus a constant which depends on the rate of cooling. This constant has a value of 1.35 in the case of very slow cooling and of 2.1 in the case of very quick cooling, an average value being 1.7. The author considers that a grey cast iron consists of graphite in a metallic matrix which "is a conglomerate of γ solution crystals with varying contents of silicon and carbon in solution," phosphides and sulphides of iron and manganese being mixed with this metallic matrix. White cast iron is stated to be a supersaturated solution of carbon, with some silicon, in γ -iron, the crystals varying in composition. Thus the cementite crystals "are those crystals of γ solid solution which first froze out of the melt," and pearlite "is the mass of the melt, caught and held as a supersaturated solid solution."—O. F. H.

Ferro-manganese; Preparation of carbon-free —. E. Wright. Iron and Steel Inst. (Carnegie research report), May, 1909. [Advance proof.]

In a previous report to the Institute (1907) E. Roberts and the author described attempts to prepare carbon-free ferro-manganese by:—1. Replacement of the combined carbon by silicon and aluminium. 2. Prolonged cementation with various oxides. 3. Bessemerisation of the alloy. 4. Fusion at a high temperature with metallic oxides. They found that the only practical process was to fuse the alloy at a high temperature with manganese oxide in a basic-lined furnace. The author has continued the experiments on the decarburisation of ferro-manganese, and has also attempted to prepare carbon-free manganese from its ore. Ferro-manganese was heated to 1600° C. with both 30 per cent. and 40 per cent. of manganese dioxide for three hours. The resulting alloy contained about the same amount of carbon with less manganese and more iron. There was a loss of 30 per cent. of metal in the first case, and 43 per cent. in the latter. The loss was not due to volatilisation of manganese. Fusion of ferro-manganese with copper oxide resulted in a slightly altered alloy, and a copper-manganese not containing carbon. Fusion with zinc oxide lowered the percentage of manganese while raising the iron, without altering the carbon content. In addition the following materials have all been tried, hematite, silica, barium peroxide, alumina, lime, magnesia, titanite oxide, ferrous and manganoous carbonates, hydrogen, oxygen, carbon dioxide, calcium and aluminium. They mostly failed, and where there was a reduction of carbon content, the method was not economically practicable. The author believes that the commercial production of a carbon-free alloy is an impossibility, because the manganese has a greater affinity for carbon than for any other element, the only elements capable of replacing carbon being aluminium and silicon, the latter yielding a silico-spiegel. In attempting to obtain a carbon-free manganese by the reduction of manganese dioxide containing 3.4 per cent. of iron oxide, heating with carbonaceous materials and with coal gas gave a carbon-ferro-manganese, while heating with carbon monoxide and hydrogen gave no metal at all. Calcium gave manganoous and calcium oxides. Zinc and iron gave no reduction. The author believes that reduction is only effected by a reagent having a greater affinity than manganese for oxygen. Aluminium and carbon are the only available elements; the former is not economical, and the latter yields a carbide, and not metal, and this carbide cannot be reduced by any practical method.—A. H. C.

Steel; Influence of treatment on the solubility of — in sulphuric acid. E. Heyn and O. Bauer. Iron and Steel Inst., May, 1909. [Advance proof.]

The authors have investigated the relationship between the mechanical and thermal treatment of steel and its solubility in sulphuric acid. A number of samples of a tool-steel containing 0.95 per cent. of carbon, were heated to 900 C., quenched in water at 14—18° C., and reheated to various temperatures from 100 to 640° C. The samples were immersed in a 1 per cent. solution of sulphuric acid and the loss in weight, after 24, 48, and 72 hours respectively, was determined. Instead of the solubility curve showing a gradual transition from the martensite of hardened steel to the pearlite of annealed steel, the curve ran up to a sharply defined maximum with the steel reheated at 400 C. and then rapidly fell away when the reheating had been carried further. The material which has this well defined state of maximum solubility has been termed by the authors osmondite, the transition stages between it and martensite being termed troostites and those between osmondite and pearlite being called sorbites. On dissolving troostites in 10 per cent. sulphuric acid out of contact with the air, they leave a residue rich in free carbon, but containing no carbide. Sorbites similarly treated yield a steadily increasing amount of carbide as the pearlite stage is approached, the carbon in pearlite being entirely in the carbide condition. Tests made on mild steel containing 0.07 per cent. of carbon gave similar results. The quenching temperature appears to have no definite relation to the solubility of carbon steels in acid, but, in the case of tungsten-chromium steels, the solubility is proportional to the quenching temperature and together with scratching-hardness tests, etc., may be employed to determine the temperature used for quenching. The solubility of steel is increased by cold-working and is proportional to the work done; as little as 2 per cent. of cold-stretching or compression can be determined by the solubility test. Micrographs and 42 tables of tests accompany the paper.—F. R.

Steel; Gases occluded in —. T. Baker. Iron and Steel Inst. (Carnegie research report), May, 1909. [Advance proof.]

HAVING reviewed previous work on the subject, the author investigated: (a), the nature and volume of the gases evolved when steel is heated *in vacuo*; (b), the relation of the critical points to the extent of this evolution; (c), the part played by the gases in the formation of blowholes. Equal quantities of converted bar having been melted were cast in an iron mould, giving one sound ingot by the addition of aluminium, and a second full of blowholes. They both contained 0.8 to 0.9 per cent. of carbon, and were heated for 11 hours a day for 10 days in a vacuum. The sound ingot gave 10.4 times its volume of gases consisting mainly of hydrogen and carbon monoxide, while the unsound ingot gave 5.2 times its volume. The maximum rate of gas evolution coincides with the Ar 1.2.3 point in both steels, and the author considers that it is not clear whether the evolution of the carbon monoxide is due to its inferior solubility in γ -iron, or to the decomposition of a ferro-carbonyl. Aluminium appears to prevent the formation of blowholes by preventing the liberation of gas during the period of solidification, and not by any prevention of the formation of carbon monoxide.—A. H. C.

Steels for gears; Contribution to the study of —. L. Revillon. Iron and Steel Inst. (Carnegie research report), May, 1909. [Advance proof.]

THE metal suitable for employment as a cogged gear-wheel should not only be easy to machine, but capable of being hardened by suitable heat-treatment without deformation, in order to prevent wear. The author has examined twenty-six steels grouped in the following classes. 1. Steels containing neither nickel nor chromium. 2. Nickel-chromium steels with low carbon-content, capable of water-hardening with or without subsequent annealing. 3. Nickel-chromium steels low in those elements, oil- or water-hardened. 4. High-percentage

nickel steels, with or without chromium. They were in the form of bar, 20 mm. (0.78 in.) in diameter, and served not only for the tests but for two pairs of gear pinion and crown, for the third speed of a speed-changing mechanism of a 12 h.p. type of motor. These gears were run under a full load continuously for seventy hours to cause wear of the teeth. The chemical composition of the steels, their recalcence points, mechanical tests and hardness both in the annealed and in the quenched and tempered states are tabulated according to the class. The variations in the properties of each of the steels under the heat treatment are discussed, and also the best methods for the employment of each in the annealed state for machining, and in the quenched state for use in a gear. The author draws the following conclusions:—1. All four classes give samples more or less suitable for gears. 2. Steels not containing nickel can be made to give a hard gear, but are relatively brittle and require a heat treatment closely adjusted to their composition. 3. Soft nickel-steels quenched in water are not sufficiently hard, but may be case-hardened and then give excellent results. 4. With an increasing percentage of carbon, steels quenched in oil or air are improved by the presence of nickel as regards resistance to shock and elongation. 5. When the nickel content is increased it is possible to obtain by a well adjusted carbon content, a steel which under simple treatment yields the best result. After annealing, air quenching is sufficient to give good hardness and good resistance to shock for machining. Very great care is however necessary in the manufacture of this class of steel as regards composition. 6. It is always possible to obtain a nickel steel answering all the requirements of a special manufacture by simple quenching without subsequent annealing.—A. H. C.

Nickel-steel riveted joints; The strength of — with special reference to resistance to slip. E. Preuss. Iron and Steel Inst. (Carnegie research report), May, 1909. [Advance proof.]

NICKEL steel having been used for the rivets of the Manhattan and Blackwell Island bridges between New York and Brooklyn, without extensive tests being carried out, the author has tested four kinds of nickel steel to ascertain whether they were suitable for rivet material and has also tested ninety-three nickel steel riveted joints. In addition to having a high shearing strength, rivet material should have a high yield point at elevated temperatures. The author has therefore tested the tensile strength at high temperatures and finds that the tensile strength and especially the yield point of nickel steel at high temperatures are higher than those of wrought iron. It was also found that nickel-steel does not become more brittle by over-heating. The ultimate strength of the most interesting joints are tabulated, and are found to be twice as strong as similar wrought-iron joints. Nickel-steel made in the electric furnace was found to be too brittle, whereas the remaining three kinds were so tough that the heads, 0.63 in. in diameter, were pulled through plates 0.3 in. thick without damage. It is suggested that the rivet shanks may be made thinner and the heads larger than those of wrought iron or mild-steel rivets as generally employed. Fairbairn, Reed, Harkness, Schwedler, Wildish, and later, von Bach have pointed out the importance of the resistance to slipping, due to the friction of the plates joined, produced by the contraction of the rivet, and the condition of the surfaces in contact. The latter was of opinion that riveted joints should be designed more with special reference to this resistance to slipping than to the shearing resistance of the rivet shanks. The author is of an opposite opinion, having found that the important part of the slipping of nickel-steel and wrought iron riveted joints took place before the working load was reached, and not, as stated by von Bach, after the joint was loaded above 50 per cent. above the working load. The author found that the slip was different on different sides of the joint, as did von Bach; that the same amount of slip took place at equal loads with rivets of both large and small diameters; that fulling reduced the slip a little, the effect of the rivet heads having more effect than that of the

lges of the plates; that nickel-steel and wrought iron rivets were equally efficacious; and that the slip of butt joints was greater than that in lap joints of the same ultimate breaking strength. The state of the two surfaces in contact had more influence than the difference in the methods of riveting employed.—A. H. C.

in-plate production; Development and present position of —. O. Vogel. Chem.-Zeit., 1909, 33, 507.

Present England produces about 650,000 tons of tin-plate per annum, the United States 600,000 tons, Germany 44,500, Austria-Hungary 10,000, Italy 24,000, and Spain 16,000. France produces a considerable quantity, Belgium none; the Russian industry is developing, the Swedish has died out. The value of the 50,000 tons produced in England is £7,900,000, of which the 17,000 tons of iron account for £3,250,000, coal for £280,000, sulphuric acid for £90,000 and palm oil for £55,000. The tin in American tin-plate varies from 2.32—1.16 per cent., or 145—57 mgrms. per 25 sq. cm. Germany, in 1907, imported 43,085 tons corresponding with 861,700 boxes or about 96.5 million plates. The five German works, at Rasselstein near Neuweid, Dillingen on the Rhine, Hayingen in Lothringen, and Hüsten and Nachrodt in Westphalia (of which the two first are the oldest and most considerable) are united in a syndicate with an office at Cologne.—A. G. L.

Pin holes in tin plate; Detection of —. W. H. Walker. J. Ind. and Eng. Chem., 1909, 1, 295—297.

For the detection of pin holes in tin plate the author makes use of the blue coloration developed at such spots with a solution of potassium ferri-cyanide stiffened with gelatin and containing a small quantity of acid to accelerate its corrosive action on the iron. The reagent contains 100 grms. of gelatin, 450 grms. of water, 1 gm. of potassium ferri-cyanide, and 1 gm. of sulphuric acid. The ferri-cyanide is added to the gelatin solution, and after cooling about 40° C., the acid is added, the reagent being prepared just before use. When a large number of plates are to be examined, the sensitiveness of the reaction may be increased by soaking the plates overnight in a dilute solution of ammonium chloride or by dipping them for 1 minute in 5 per cent. sulphuric acid.—A. S.

Iron and steel; Preservation of —. A. S. Cushman. Iron and Steel Inst., May, 1909. [Advance proof.]

The author explains the electrolytic theory of the corrosion of iron and steel (see this J., 1907, 1051), and the action of certain oxidising agents, such as chromic acid, and reducing agents, such as pyrogallol, in inhibiting rusting (see this J., 1907, 1201). The value of the different protective coatings used is then discussed, and the results of tests recorded. The use of soldering solutions, such as zinc chloride, in ordinary galvanising is considered to be a dangerous practice since some of this solution may be included under the zinc coating, and so promote electrochemical action. The same objection applies to the cold galvanising process, owing to a similar inclusion of some of the electrolyte, and the formation of electro-negative elements of iron and zinc is a possible difficulty in the hardening process. The author shows that tin does not give such an efficient protecting coat as it should do on account of the difficulty in applying it economically to the surface of steel so that it shall give a coating free from pinholes. In the case of pigments it had been previously suggested by the author that, owing to their inhibitive action against rusting, the slightly soluble compounds should constitute the most suitable material for the first coating on iron and steel surfaces. It has, however, since been shown that this protective power may be destroyed by the presence in the pigment of a trace of iron or any soluble impurities that tend to stimulate corrosion. About fifty commercial pigments were tested in the following manner:—A series of bottles, all of the same size, were fitted with two-hole stoppers and connected by glass tubes, so that a current of air could be drawn readily through the whole series. Two carefully weighed samples of sheet steel, each having a surface area of 4 sq. in. were placed in each bottle, together with 10 c.c. of one

of the pigments and 100 c.c. of distilled water. A rapid current of air was then drawn through the series of bottles for seven days in some experiments and for three weeks in others, the loss in weight of the steel after this treatment being taken as a measure of the corrosion. From the results of these experiments the pigments are classified into three groups, *viz.*, Inhibitors such as zinc oxide, white lead (Dutch process), and willow charcoal; Indeterminates such as white lead (quick process), red lead, and litharge; Stimulators such as lampblack, ochre, and graphite. It is also shown that pigments that are good conductors of electricity should not be applied directly to iron and steel. The following rapid test of corrosive action was found to give reliable results:—"The pigments to be tested are rubbed up with sufficient water to make thick water-colour paints, and are then flowed or brushed upon the clean blades of table knives. After the coatings are dry, the knives are laid on a wet blotter and covered with a sheet of blotting paper. At the end of 48 hours the surface is cleaned off with running water and a stiff brush." Large scale tests of paints are now in progress near Atlantic City, N.J., 600 large plates, representing three kinds of steel, mounted in wooden frames facing the sea shore having been painted with single paints and various mixtures. Similar tests are being carried out in Pittsburgh to test the resistance to corrosion of steel wires of varying composition galvanised in various ways. In the case of steel that must be used without any protective coating, resistance to corrosion is dependent on the purity of the material, its freedom from segregation, and the care with which it has been worked.—O. F. H.

Platinum production of Russia. Chem. Ind., 1909, 32, 270.

The production of platinum in Russia increased considerably during the past year. The figures for the last three years were as follows:—

	Quantity.	Value.
	lb.	£
1906.....	11,592	801,000
1907.....	10,761	1,126,000
1908.....	13,975	1,570,000

—A. S.

Platinum; Melting point of —. W. Waidner and G. H. Burgess. Compt. rend., 1909, 148, 1177—1179.

The fact, observed by Féry and Chéneveau (this J., 1909, 313), that the melting point of platinum, as determined with the optical pyrometer, is dependent on the nature of the atmosphere in which the fusion is effected, does not account for the different values obtained by previous experimenters with this method, since the fusions in these experiments were made under similar conditions in the presence of air; the discrepancies are probably due to inexact knowledge of one of the constants in Wien's equation. —F. SODN.

[Cyaniding.] Utilisation of waste heat in slimes treatment. A. Salkinson. J. Chem. Met. and Min. Soc., S. Africa, 1909, 9, 308—309.

The chief advantage gained by using heated cyanide solutions in the treatment of slimes is the greater rapidity with which the slimes settle, in consequence of which a smaller number of settling tanks are required. Usually the waste heat from the mill engine can be employed to heat the solutions, the latter being used in place of the cooling water employed in the condensation of the exhaust steam. A large amount of data are tabulated in which the extraction during one month while using cold solutions is compared with that obtained during a similar period when using heated solutions. The result shows that six vats did more work with heated solutions than nine did with cold solutions, the respective extractions being practically the same, also that 20 per cent. more of the hot solution was precipitated for the same amount of zinc with a precipitation of 94.5 per cent. compared to only 91 per cent. from cold solutions.—F. R.

[*Gold cyaniding*] *Notes on precipitation.* M. Smith. J. Chem. Met. and Min. Soc., S. Africa, 1909, 9, 300—302. In the precipitation of gold and silver from cyanide solutions, the amount of zinc usually allowed is 1 cb. ft. of shavings per ton of solution per 24 hours. This amount the author considers excessive and tends to load the solutions with compounds of zinc which subsequently form "white precipitate" in the precipitation boxes. He has found it possible to reduce the amount of zinc to three tons of solution per cb. ft. of zinc per 24 hours, in the sands precipitation boxes, and to 4 and 5.4 tons of solution respectively in the two slimes precipitation boxes. The zinc was packed quite loosely in the trays to a depth of only 9 in. and a system of dressing the boxes was adopted to prevent the mixing of the old and new shavings. The zinc from the top compartment in the weak or slimes precipitation box was used to replenish that in the strong or medium solution boxes, and each of the trays from the other compartments in the slimes box were lifted up bodily and moved up one place, the last compartment being then filled with fresh zinc. Since adopting these modifications practically no "white precipitate" has been formed and the sump solutions, which previously were found to contain 0.6 dwt. of gold per ton of solution in the strong sump and 0.225 dwt. in the medium and weak sumps, now assay only a trace of gold.—F. R.

Gold and tellurium: Fusibility of mixtures of —. H. Pélabon. Compt. rend., 1909, 148, 1176—1177.

GOLD is readily soluble in molten tellurium, a pasty solution being obtained if the proportion of gold exceed 60 per cent. The fusion curve indicates the existence of a compound, Au_2Te_3 (43.59 per cent. of gold), solidifying at 472° C., but no other compound appears to be formed between these elements. On strongly heating the pasty mixtures, rich in gold, tellurium is driven off and finally, at 1065° C., pure liquid gold remains.—F. SOBES.

Silver ore treatment in Mexico. R. Linton. J. Chem. Met. and Min. Soc., S. Africa, 1909, 9, 307—308.

For the treatment of refractory manganiferous silver ores, the author mixes the crushed ore with salt and adds a 5 per cent. solution of sulphuric acid, allowing the mixture to stand, with occasional agitation for 24 hours. The manganese present in the ore causes an evolution of chlorine which renders the ore amenable to treatment by cyanide. The acid solution is filtered off, the ore washed and then leached with a 2 per cent. solution of potassium cyanide. Extractions of from 60 to 94 per cent. have been obtained in the laboratory.—F. R.

Cupellation experiments; the thermal properties of cupels. C. O. Bannister and W. N. Stanley. Inst. Min. and Met., May 20, 1909. [Advance proof.]

In seeking an explanation of the differences known to exist between bone-ash and patent (magnesian base) cupels when in actual use, the thermal properties of cupels have been investigated by the authors. By means of a special apparatus which is described, the relative diffusivities of heat were determined for various brands of cupel, both at 100° C., and during the actual cupellation process. The patent cupels were found to have a higher diffusivity and a greater specific heat than the bone-ash cupels, and it was noticed that during cupellation at the same muffle temperature, the actual temperature of the cupelling button was much lower in the former than in the latter case. During experiments in the cupellation of silver with lead, considerable differences were also noted in the rate of cooling and in the time required for the solidification of the silver beads. It was thus found that, after being withdrawn from the same muffle temperature, silver beads take longer to solidify and "spit" on patent than on bone-ash cupels; and that spitting is more liable to occur when the latter kind of cupel is used.—W. E. F. P.

Alamosite: a new lead silicate from Mexico. C. Palache and H. E. Merwin. Amer. J. Science, 1909, 27, 399—401.

The new mineral, which was found near Alamos, Sonora, Mexico, has the composition, PbSiO_3 , and is closely

analogous to wollastonite (CaSiO_3) in form, habit, and composition. It occurs in radiated aggregates of minute colourless and transparent fibres, which give a snow-white appearance to the mass. The optical and physical properties were determined. It is easily reduced to charcoal to metallic lead; and is soluble in nitric acid with strong gelatinisation. Alamosite is very similar in appearance to barysilite, but may be readily distinguished from it by its optical characters.—F. R.

"Hardhead" [residue from tin smelting]; Bessemerising of —. D. M. Levy and D. Ewen. Inst. Min. and Met., May 20, 1909. [Advance proof.]

THE objects of the investigation, which is still proceeding are to determine the suitability or otherwise of a Bessemerising process for the profitable recovery of value from hardhead, and also the rate at which the constituent (mainly tin, arsenic, and iron) are oxidised and eliminated during such process. The material used in the experiments contained 17.92 per cent. of tin, 21.92 of arsenic and 52.90 of iron. On heating a charge to fusion in a crucible covered with a clay hood, and blowing a gentle current of air through it, a considerable evolution of heat occurred, indeed sufficient to keep the charge fused without external heat. Cooling curves taken with 500 grm. charges under exactly similar conditions, both with and without blowing, indicated an increase in temperature of 362° C. during a 15 minutes' blow with cold air. Similar charges were subjected to the Bessemerising process for periods ranging from 15 seconds to 15 minutes, the products—consisting of "metallic button," slag, and fume—being examined in every case. It was found that although a high degree of concentration of the nickel and cobalt had occurred in the metallic button, the small increase obtained in the tin content was of no practical advantage. The amount of tin in the slags varied, the lowest obtainable under laboratory conditions being 7 per cent. (much of which appeared to be in the form of hardhead held mechanically), with 2 to 3 per cent. of arsenic, 50 of iron, and 25 of silica. The condensed fume adhering to the crucible cover was found to contain about 90 per cent. of tin oxide and 0.1 per cent. of arsenic, while the fume condensed in the flues consisted of arsenious oxide, tin oxide, and fuel-ash in varying proportions, the percentage of tin increasing, and that of arsenic decreasing as the furnace end of the flue was approached. The authors claim that the feasibility of Bessemerising hardhead has been clearly demonstrated, and are of opinion that actual practice alone will show whether slags of sufficiently low tin content can be obtained to make the process a commercial success.—W. E. F. P.

Tantalum; Analysis of ores of —. E. S. Simpson. Chem. News, 1909, 99, 243.

THE following method of analysis of tantalum ores used in the laboratory of the Geological Survey of W. Australia, gives results for the combined oxides of tantalum and niobium, which, in the absence of appreciable quantities of titanium oxide, are accurate to within 0.1 per cent. The ore is fused with potassium hydroxide the fused mass extracted with water, the liquid acidified with a definite amount of hydrochloric acid, boiled to effect complete solution of the bases, and then diluted and boiled to precipitate the hydroxides of tantalum and niobium ($\text{Ta}_2\text{O}_5 + \text{Nb}_2\text{O}_5$). The moist precipitate is dissolved in water acidified with hydrofluoric acid, the solution treated with potassium fluoride and concentrated and the successive crops of crystals removed (see this J. 1906, 681). The niobium in the final mother liquid is precipitated as hydroxide, weighed as oxide, and its amount deducted from the amount of mixed oxide determined in a second portion of the sample. The difference gives the amount of tantalum oxide. A solubility allowance of 2 mgrms. of tantalum oxide, Ta_2O_5 , is made for each 1 c.c. of liquid from which the final crystallisation of the potassium tantalum fluoride is made. Tin, iron, manganese, etc., are determined in the original filtrate from the mixed hydroxides. In reply to criticism made upon this method by Giles (Chem. News, 99, 1), the author points out that in order to obtain a fused mass readily soluble in water (with the exception of carbonate

of iron, yttrium, etc., which are dissolved by subsequent addition of hydrochloric acid) a proportion of 6 parts of potassium hydroxide to one part of the mineral is required. Under these conditions the decomposition of manganotantalite was complete at a low red heat in 10 minutes, whilst 20 minutes were required for the decomposition of ferrotantalite, euxenite, fergusonite, and stibiotantalite. In each case the powdered ores were passed through a 90-mesh sieve. The decomposition of cassiterite (finely ground in an agate mortar) required 45 to 60 minutes. A nickel crucible is best for the determination of tantalum, niobium, and tin, whilst for the determination of iron, manganese, yttrium, etc., the fusion is made in silver, and the hydroxides of tantalum and niobium (which are contaminated with silver) are rejected. Antimony, in, *e.g.*, stibiotantalite, is precipitated with the tantalum and niobium. The precipitate is digested with ammonium sulphide to remove the antimony, and the residual oxides again fused, reprecipitated and again digested. "Creeping" of the alkaline mass during the fusion is prevented by fixing the crucible in a hole in asbestos millboard one-eighth inch in thickness in such a manner that only about a quarter of the crucible is below the board. The bottom of the crucible may then be heated to dull redness, whilst the upper edge is too cool for "creeping" to take place. As a further precaution the lid of the crucible should be made distinctly convex, so that particles of material projected against it drop back from the centre into the crucible instead of travelling to the side.

—C. A. M.

Tungstic acid: Determination of — in low grade wolfram ores. H. W. Hutchin and F. J. Tonks. *Inst. Min. and Met.*, May 20, 1909. [Advance proof.]

THE process described is a modification of the mercurous nitrate method, in which fusion with alkalis is replaced by digestion with caustic soda solution, by which means a large sample may be conveniently and quickly operated upon. It consists in digesting the finely-powdered ore with 20 c.c. of a 25 per cent. solution of caustic soda (free from chlorides) on a water-bath for 30 to 45 minutes, filtering, adding a little sodium peroxide to oxidise any decomposition products of sulphides, and diluting to 50 c.c. An aliquot portion, after filtering, is acidified with dilute nitric acid, then made alkaline with ammonia, boiled, and filtered. The filtrate, after being slightly acidified with dilute nitric acid, is precipitated with excess of mercurous nitrate solution followed by a few drops of dilute ammonia, and is warmed and stirred to promote rapid settling of the precipitate. After filtering and washing with weak mercurous nitrate solution, the precipitate and paper are ignited together in a porcelain, in the absence of arsenic, a platinum, crucible, the residue being tungstic acid. The above quantity of caustic soda is stated to be sufficient for the decomposition of charges containing up to 0.4 gm. of tungstic acid, the attack being very rapid. The mercurous nitrate solution is prepared by heating 2 or 3 oz. of mercury with 5 c.c. of nitric acid of sp. gr. 1.4 and 75 c.c. of water early to boiling for 1½ hours, allowing to stand overnight, and then diluting to 400 c.c.; 20 c.c. of this solution are sufficient for most assays. The method is not applicable in the presence of scheelite, which is only partially attacked under the conditions of the assay. Arsenic, if present in the ore, is partly dissolved out by the caustic soda and subsequently precipitated by the mercurous nitrate; but the authors find that by burning the precipitate and filter-paper together, as above stated, the effect of arsenic is practically a negligible factor in the case of ores containing 100 lb. or less of tungstic acid per ton. The great discrepancies existing between the assay-results obtained on the same ore by the above and the *aqua regia* methods has led the authors to determine the solubility of tungstic acid in *aqua regia* under various conditions. They find that the presence of arsenic and fluorides in the ore greatly increases the amount of tungstic acid retained by the acid liquor, indicating that these substances should be removed before applying the *aqua regia* treatment.—W. E. F. P.

Aluminium welding. [Aluminium; Action of acids on.] M. U. Schoop. *Electrochem. and Met. Ind.*, 1909, 7, 193—194.

No entirely satisfactory solder has yet been discovered for uniting aluminium, but for men skilled in "lead burning," the operation of autogenous welding presents no special difficulty. Large aluminium vessels for distillation and similar purposes are now made by this means. An illustration is given of a container about eight feet both in height and diameter. For welding thin sheets the oxy-hydrogen blowpipe is sufficient, but for thick sheets it is advisable to use the oxy-acetylene burner. It is necessary that the gases be intimately mixed as they leave the burner, and to avoid back-lighting, the flow of gas must be greater than the speed of propagation of the explosion. Special so-called "saving burners" may be used in which the oxygen supply is automatically cut off and the hydrogen supply reduced as soon as the burner is laid aside. A long series of tests have been made in Zürich to determine to what extent aluminium is attacked by acids. It was found that the English metal withstood the attack better than that of other European manufacture. The structure and condition of the surface, however, largely affects the results. Hard rolled aluminium with a highly polished surface is the least attacked, but if it is heated until a chip of wood on its surface begins to char, the resistance of the metal to acid attack is reduced to that of cast aluminium.—F. R.

Direct reactions; Conditions necessary for —, and the direction of the electric current generated by the action of sulphur on metals. A. Colson. *Compt. rend.*, 1909, 148, 1183—1186.

IF two bodies are capable of combining with a third, the compound produced at a given temperature is not necessarily that which gives rise to the liberation of most heat. Copper, for instance, is attacked by oxygen or sulphur at a much lower temperature than is aluminium, although the heat developed in the latter reactions is much greater than in the former. Similarly, when rods of copper and aluminium are placed in yellow ammonium sulphide, the direction of the electric current set up, as well as the appearance of the copper, shows that this metal is attacked by the sulphur, and if the copper is replaced by silver, in spite of the large difference between the heats of formation of silver sulphide and aluminium sulphide, the direction of the current indicates that silver is the metal attacked. In order to prophesy the course of such a reaction, it is considered necessary to know the "zones of reaction" of the compounds concerned, *i.e.*, the temperatures at which they are formed and dissociate. For example, the action of aluminium on chromic oxide is thought to depend on the fact that alumina, unlike chromic oxide, has no dissociation pressure at about 2000° C., and not on its heat of formation being greater than that of chromic oxide.—F. SODX.

PATENTS.

Ore concentrators. H. J. Haddan, London. From C. W. Eccleston, Los Angeles, Cal., U.S.A. Eng. Pat. 19,163, Sept. 11, 1908.

THE concentrator consists essentially of a table having a flexible surface suspended by wires from its sides and held in a state of high tension. The surface is furnished with riffles extending part or the whole length of the table and at right angles to the tension. Means are provided for imparting a rapid longitudinal reciprocating motion to the table. Blocks supported by truss-rods passing under the table at different parts enable the level of the surface to be variably adjusted if required. Ore pulp is fed on to the table and gradually moves to the discharge end owing to the reciprocating motion of the table. It is subjected to a transverse stream of water which carries the tailings over the lower side, the concentrates being discharged at the further end.—F. R.

Ore concentrators. P. M. Justice, London. From H. S. Duell, New Rochelle, U.S.A. Eng. Pat. 28,365, Dec. 29, 1908.

THE apparatus comprises a table having a sloping concentrating surface, which may be flat or concave. The inclination of this table may be altered at will, and means are provided by which the whole system can be agitated in a direction perpendicular to the angle of slope. The essential feature of the apparatus consists however in the number of sinuous "riffles" or small vertical partitions which extend from the elevated portion diagonally across the surface of the concentrator and tend to converge at the opposite lower corner. The undulation of these "riffles" progressively decreases in amplitude from the upper to the lower corner of the table. Along the top edge of the concentrator extends a longitudinal trough divided into two or more divisions by adjustable stops. In this way the ore, fed into a hopper at the right hand corner, travels towards the other end, so that before being washed on to the surface by a stream of water, it becomes roughly classified. A series of hoppers is arranged along the lower edge of the table for the reception of the classified products.—C. A. W.

Ores; Process for testing or reducing — E. P. Welch, Denver, Colo. U.S. Pat. 919,663, April 27, 1909.

FINELY powdered ores are mixed with a material containing 20 parts of potassium chlorate, 2 of sodium peroxide and manganese dioxide, 13 of wheat flour, and 4 of argol, and the whole is ignited.—A. G. L.

Steels; Treatment of — for industrial purposes. Soc. Schneider et Cie, La Cressot, France. Eng. Pat. 24,241, Nov. 11, 1908. Under Int. Conv., Jan. 25, 1908.

THE treatment is to prevent the liability of armour plates, etc., made of certain steels, developing blowholes and rents caused by internal tension, during cooling. The metal is cooled from well above the critical point in heating, and the cooling retarded for a time at about 250° C. above the critical point in cooling, or the metal is partially cooled and then re-heated, care being taken not to heat to the critical point in heating. Cooling is then allowed to proceed and the exothermic reactions that usually occur at the lower critical point are entirely prevented, the steel cooling without strain.—F. R.

Tool-steel. J. M. Darke, Lynn, Mass., Assignor to General Electric Co., New York. U.S. Pat. 919,544, April 27, 1909.

A LOW-CARBON steel is claimed containing 13.5 per cent. of tungsten, less than 0.5 of chromium, and more than 2 (e.g., 3) of manganese; 0.25 of vanadium may also be added.—A. G. L.

Steel; Manufacture of — J. dit V. Fattelay. Fr. Pat. 396,248, Jan. 20, 1908.

IN the method proposed, a gyratory movement is imparted to the steel as it is poured out of the receptacles into the ingot moulds. To this end, the tap-hole at its upper portion is of helicoidal form; the lower portion, however, is made round in order to regulate the jet of metal. In this way the emerging stream offers less surface to the surrounding air and oxidation is prevented. Moreover, in the movement of rotation, the slag becomes pulverised, and, not being sufficiently heavy to be drawn down into the mass of the metal, remains floating on the surface.—C. A. W.

Steel; Manufacture of — F. P. Jones. Fr. Pat. 396,635, Nov. 23, 1908.

THE process relates to the manufacture of steel from crude cast iron or iron scrap together with iron ore or other oxides. The method is advantageous when the metals contain such high percentages of phosphorus or silica as to retard injuriously the working of the ordinary basic open hearth process. The metal undergoes two distinct treatments, being first submitted to a process whereby the silicon, carbon, phosphorus, and sulphur are wholly or partially eliminated, and then to a process of oxidation.

IN practice, the molten metal is transferred directly from the cupola furnace to a Bessemer converter with basic lining. It may there be subjected to two distinct blowings or to a single continuous blow. In the first method, a small charge of lime is added, the converter raised and the metal freed from silicon and partially from carbon. The converter having been turned over as much of the slag is poured out as is possible without loss of metal. The necessary amount of lime, together with oxides, if these are required, is added, the converter raised and the blow continued until the metal is decarburised. The slag, rich in phosphorus and valuable as manure, is poured off and the molten metal directed to the hearth of a furnace with basic lining, where it comes into contact with a mass of the unrefined metal, the quantity of the latter being regulated according to the quality of the steel it is desired to obtain, and being such that it is rapidly freed of its silica and phosphorus. If lime and oxides be added to the basic furnace before or during the charging of the latter, the final operation will be hastened so that more of the unrefined metal may be employed and a greater economy of working obtained. Finally, after removal of the unrefined metal, the slag may be retained on the hearth for the purification of subsequent charges. If the oxidation in the converter be carried out in one blow, the whole of the lime is added to the charge at once, after which the operation goes forward as before.—C. A. W.

Leaf-metal and the like, particularly leaf-gold; Process and apparatus for manufacturing — L. Kurz, Fürth, Germany. Eng. Pat. 28,081, Dec. 24, 1908.

3.7 GRMS. of castor oil and 26.25 grms. of nitrocellulose are dissolved in each litre of a colourless mixture consisting of 50 parts by measure of amyl acetate, 45 parts of benzene, and 5 parts of methyl alcohol. Sufficient finely powdered metal or alloy to form a thin paste is stirred in, and a thin stream of the mixture poured on to water or other suitable surface, over which it spreads, forming a floating film which rapidly becomes solid owing to the evaporation of the amyl acetate, accelerated by the benzene. When solid, the leaf is lifted off, dried, and polished. Details are given of an apparatus for carrying out the process.—F. R.

Precious metals; Process of extracting — from their ores. W. L. Imlay, Conestoga, Pa., Assignor to W. L. Imlay Rapid Cyanide Process Co., South Dakota. U.S. Pat. 919,434, April 27, 1909.

THE ores are powdered in, or conveyed through, a series of lixiviators, in which they are exposed to the solvent action of potassium cyanide solution, both ores and solution being alternately heated and cooled, and also agitated and scoured whilst exposed to the action of light and air.—A. G. L.

Gold; Process for the recovery of — from solutions [see water] containing it. J. D. Riddel A.-G. Ger. Pat. 208,859, March 19, 1907.

THE solution containing gold, for example sea-water, is filtered through ordinary zeolites, or through zeolites containing stannous oxide, ferrous oxide, or other bases capable of precipitating gold; or bases capable of precipitating gold are added to the solution in the form of salts before filtering through ordinary zeolites. It is stated that by this process the recovery of gold from sea-water becomes remunerative. The filter may be suspended in the sea at places where the water is in continual motion owing to currents, etc.; or they may be fastened to travelling ships.—A. S.

Tin; Process of removing and recovering — J. Elkes, Mt. Pleasant, Pa. U.S. Pat. 919,839, April 27, 1909.

TIN is removed from scrap by immersing in a heated bath of ammonium sulphide containing excess of sulphur. Hydrochloric acid is then added to precipitate tin sulphide, which is converted into tin dioxide by heating. The tin dioxide is then reduced by means of a carbonaceous substance, e.g., coal.—A. G. L.

urnace for volatilising zinc ores; Revolving —. H. H. Hughes, Springfield, Mo. U.S. Pat. 920,143, May 4, 1909.

HE furnace consists of an inclined cylinder provided at its upper end with a central longitudinal tubular trunnion bearing, and a fixed annular hood of greater diameter than the furnace. This hood communicates with the interior of the furnace by means of openings corresponding with similar openings in the wall of the cylinder. At the same end of the cylinder is placed a hopper provided at its bottom with a cylindrical feed-tube which projects into the furnace through, and fits closely within, the trunnion bearing. Means are provided for withdrawing volatilised ore from the hood.—A. G. L.

metal; Process for refining —. J. H. Reid, Newark, N.J. U.S. Pat. 920,391, May 4, 1909.

HE ore is first melted (by electric means) and then "mixed" with a reducing gas (e.g., carbon monoxide), as to produce a frothy mass. This mass is then rotated and its surface exhausted.—A. G. L.

soldering; Autogenous —. J. Knappich. Fr. Pat. 396,306, Nov. 7, 1908. Under Int. Conv., Nov. 9, 1907.

HE coal gas employed is increased considerably in calorific power by saturating it with the vapours of volatile hydrocarbons such as benzol, gasoline, petroleum ether, &c. To this end, the gas may be made to bubble through the liquid hydrocarbon contained in a carburettor of suitable design, or allowed to pass through a porous mass saturated with the liquid. The same end would be attained by allowing the latter to fall in drops into the carburettor.—C. A. W.

aluminium and its alloys; Method of soldering pure —. O. de Andrade. Fr. Pat. 396,345, Nov. 14, 1908.

HE solder employed has the composition: zinc, 150 parts; tin, 50; aluminium, 40; silver, 12; and phosphorus, 1 part, all the constituents being quite pure. The metal is melted in a plumbago crucible and the other metals added in order of fusibility, the liquid being kept well stirred. The phosphorus is added, with stirring, only at the moment of pouring, when the crucible has been removed from the fire. The solder is employed without flux, but, while the work is still hot, a little stearine paraffin is passed over the weld. All the tools employed are of aluminium.—C. A. W.

slags [Blast-furnace]; Treatment of — with a view to facilitating their transport. Ges. für Förderanlagen E. Heckel m.b.H. Fr. Pat. 396,769, Nov. 20, 1908.

HE molten slag without previous granulation is brought directly into contact with the jet of water of a hydraulic motor. In practice, the water emerging from a tuyère is along the bottom of an open receptacle of V-shaped section, where it meets with the slag which is run in at the top, the mixture passing away into a chamber tube. The diameter of this tube being enlarged progressively in the direction of the motion, a considerable hydraulic pressure is set up, so that the mixture of slag and water may be conveyed to any desired distance or height. The granulation is subsequently effected in the ordinary way by bringing the whole into contact with a large quantity of water.—C. A. W.

iron; Process for increasing the ductility of —. Siemens und Halske A.-G., Berlin. Eng. Pat. 17,610, Aug. 21, 1908. Under Int. Conv., Sept. 26, 1907. Addition to Eng. Pat. 17,350 of 1908.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A).—ELECTRO-CHEMISTRY.

Carbon electrodes; Manufacture of —. G. A. Roush. J. Ind. and Eng. Chem., 1909, 1, 286—295.

THE materials used in the manufacture of carbon electrodes are coke, hard and soft pitch, coal tar, and petroleum oil; in some cases when it is desired to obtain electrodes of better mechanical wearing properties, a small portion of the coke is replaced by lampblack. Except in special cases where a relatively high content of ash is not objectionable, petroleum coke, containing 6—10 per cent. of volatile matter and 0.02—0.06 per cent. of ash, is used. The hard pitch should soften at 160°—170° F. and contain 40—45 per cent. of matter insoluble in benzene. The petroleum oil is so-called "summer oil," the last distillate in the refining of crude oil. The coke is crushed to $\frac{3}{4}$ -in. size and freed from volatile matter by calcining in cylindrical firebrick retorts arranged in a furnace so that the fire plays all round them. The cost of calcination, including fuel, labour, loss of weight, etc., is about £1

per ton. The calcined coke is ground to dust of varying degrees of fineness according to the size of electrodes to be made (see following table).

	Small sizes.	Medium sizes.	Large sizes.
	Per cent.	Per cent.	Per cent.
On 100-mesh sieve	0.8	5.0	10.0
" 140-mesh "	7.7	17.3	20.5
" 200-mesh "	27.5	21.7	19.0
Through 200-mesh sieve	64.0	50.0	50.5

For producing the finest dust a Raymond impact pulveriser is used, in which a grinding wheel, suspended from one end of a rotating arm, is forced by centrifugal action against a heavy ring. The crushed material is caught by an ascending current of air from a fan, and the fineness of the dust collected is controlled by regulating the speed of the fan, the heavier particles being allowed to fall back into the pulveriser. With this machine it is possible to obtain without bolting, dust of such fineness that 98 per cent. will pass a 100-mesh sieve, and 92 per cent. will pass a 200-mesh sieve. Coarser dusts are produced either in the same machine, or in the ordinary burr mill, with or without bolting. The hard pitch is crushed to $\frac{1}{2}$ -in. size. The composition of some of the mixtures commonly used is as follows:—(1). For ordinary electrodes: coke, 325 lb.; hard pitch, 110 lb.; oil, 1 gall. (2). For a somewhat finer dust or a pitch of higher melting point: coke, 325 lb.; hard pitch, 115 lb.; oil, 2 galls. (3). For a coarse dust: coke, 325 lb.; hard pitch, 40 lb.; melted soft pitch, 4 galls.; oil, 1 gall. (4). For a "carbon" to stand heat and wear but not to be used as electrode: coke, 325 lb.; lamp-black, 20 lb.; hard pitch, 30 lb.; tar, 10 galls. The ingredients are mixed for about 20 mins. in steam-jacketed kettles provided with revolving blades. The hot mixture, having a temperature of 265°–275° F., is placed in heavy cast-iron hoops, and by means of a hydraulic press is compressed into cheeses or plugs about 6 ins. thick and of the same diameter as the opening in the press in which the "carbons" are subsequently formed. The plugs are allowed to cool to 200°–240° F. and then forced through dies which are usually about 3–5 per cent. larger than the desired diameter of the finished "carbons." The hydraulic press used is provided with a steam coil to keep the material at the requisite temperature. The pressure used must not be too high, otherwise the material expands so rapidly on emerging from the die that the "carbon" splits radially from end to end. The "carbons" are cut to length whilst hot, spoiled or defective ones being rejected. The "green carbons" are then packed firmly in sand in a gas-fired furnace having flues in the bottom and walls so that the furnace-chamber is heated uniformly. The top layer of "carbons" is damaged by oxidation during the cooling of the furnace, and is therefore usually made up of "green carbon scrap," which is afterwards ground and used in making battery carbons. The baking of the electrodes occupies from 10 to 14 days, the temperature being increased steadily, finally to 1020° C. The furnace is allowed to cool for 4 or 5 days before being opened. The finished "carbons" should have a resistance of about 0.0016 ohm per 1 inch cube, and be capable of safely conducting a current of 25 amperes per sq. in. of cross-section. They are also tested for apparent density, real density, and content of ash. In the case of ordinary electrodes the apparent density varies from 1.55 to 1.70, the real density from 1.95 to 2.05, and the ash content from 0.1 to 0.3 per cent. Electrodes of amorphous carbon to be converted into graphite by the Acheson process are prepared in a similar manner, the composition of the mixture used being: coke, 325 lb.; hard pitch, 103 lb.; soft pitch, $\frac{1}{2}$ gall.; oil, 1 gall.; iron oxide, 5 lb. The finished "carbon" ready for graphitisation should contain about 1.5 per cent. of ash and have a real density of at least 2. All the scrap produced must be ground and worked up again in the process, since carbon containing iron cannot be used for battery purposes.—A. S.

Electrolysis of glycerol and glycol. Löb and Puivernmacher. See XVI.

PATENTS.

Electrical effluvia; [Ozonising] Apparatus for producing and utilising —. L. Gerard, Brussels, Belgium. Eng. Pat. 1253, Jan. 18, 1908. Under Int. Conv. April 19, 1907.

CONCENTRIC metallic tubes are employed as electrodes the distance between the latter gradually increasing towards the ends of the cylinders. The electrodes are separated by dielectrics, in the form of tubes of glass mica, etc., these being supported at one place only so that they are free to expand in all directions, and the electrodes are split or cut in order to allow for expansion. The apparatus is supported in an insulated metallic bath, containing a "cooling medium of non-conducting liquid of high calorific and specific inductive capacity," such as petrol, Canada balsam, resinous solutions, mineral oils, etc., and the inner electrode is cooled by the current of gas entering the apparatus.—B. N.

Ozone; Apparatus for the production of —. A. Vosmaer. Assignor to the United Water Improvement Co. Philadelphia, Pa. U.S. Pat. 919,403, April 27, 1909.

THE air to be ozonised is passed through a vessel in which a number of ozonisers are placed parallel to the path of the air. The ozonisers consist of rods provided with electrodes around which are concentrically supported tubular dielectrics surrounded by outer tubular electrodes. The rod, dielectric, and outer electrode of each element are spaced equally apart, the air being passed through the tubular dielectric.—W. H. C.

Insulating material; Process of manufacture of an —. A. Kraenzlé. Fr. Pat. 396,766, Nov. 17, 1908.

BITUMINOUS substances, dissolved in alkali, are mixed with barium peroxide, the latter being transformed into barium hydroxide and carbonate. The elimination of oxygen induces a rapid hardening of the bitumen, and this, uniting with the barium carbonate, forms a compact and homogeneous mass, which is impermeable to water, and which is a bad conductor of electricity, sound, and heat.—B. N.

Electrolyte for electric batteries. The New Ignition Syndicate, Ltd., and W. J. L. Sandy. Fr. Pat. 396,905, Nov. 30, 1908. Under Int. Conv., May 14, 1908.

THE electrolyte contains chromic acid, an acid alkali sulphate, and hydrochloric acid, the following proportions of substances being employed:—600 grms. of sulphuric acid, 60° B., 400 grms. of hydrochloric acid, 21° B., 1000 grms. of chromic acid (or an equivalent quantity of sodium or potassium bichromate), 200 grms. of sodium or potassium hydroxide, and 4200 grms. of water. —B. N.

(B).—ELECTRO-METALLURGY.

Copper sulphate; Electrolytic preparation of — from "cement waters." G. B. Rambaldini. L'Ind. Chimica, 1909, 9, 1—4. Chem. Zentr., 1909, 1, 1675.

The author describes a method of obtaining pure copper from "cement copper waters." An electrolytic cell is divided into two compartments by a non-conducting partition extending only to half the height of the cell. In one compartment is placed the "cement water," and in the other a dilute acid solution of copper sulphate. The level of these liquids is below the top of the partition, but they are covered with dilute sulphuric acid to a height above the top of the partition. On passing a current between copper electrodes placed in the two compartments, copper separates from the "cement water" at the cathode, whilst at the anode, copper is dissolved. By changing the electrodes at intervals and renewing the liquids in the two compartments, the production of a pure solution of copper sulphate proceeds continuously.

PATENTS.

Electrotypes; Apparatus for the production of — and for electroplating. S. O. Cowper-Coles, London. Eng. Pat. 9695, May 4, 1908.

The apparatus is intended for the production of electrotypes such as voice records or printing surfaces. It comprises an electrolytic vat in which a convenient number of printing blocks, rendered capable of conducting electricity by a coating of graphite, are secured by means of adjustable grips on the under surface of a flat holder, so that they constitute a cathode. This cathode can be rotated over anode plates arranged beneath it in the vat, and is connected to the source of electricity by means of brushes which impinge directly on the shaft. This last being hinged, the whole system of plates can be raised to a perpendicular position, so that the condition of the deposits may be inspected at any moment. The electrolyte is circulated through spraying pipes directly on to the surface of the records, a more rapid circulation being assured by means of vanes secured to the cathode holder. If desired, the apparatus may be arranged so that each record rotates about its own axis as well as about the central axis of the holder.—C. A. W.

Distillation-furnace. W. M. Johnson, Assignor to The Continuous Zinc Furnace Co., Hartford, Conn. U.S. Pat. 920,473, May 4, 1909.

The furnace is an electric furnace consisting of a vertical chamber provided with an interior casing of non-conductive and refractory material at a distance from the walls of the chamber. The casing is built up in sections and is provided with a number of upwardly inclined perforations. Electrodes are placed at top and bottom of the casing. A hopper is provided at the top of the chamber, a discharge door near the lower end, and an outlet for the vapour near the upper end.—A. G. L.

Uminium and other metals; Art of extracting —. H. S. Blackmore, Mount Vernon, N.Y. U.S. Pat. 920,893, May 4, 1909.

SUBSTANCES containing the metal to be produced are maintained in the fused state by means of an alternating current, the metal being liberated by the action of a direct current, in the presence of a substance capable of uniting with the electro-negative constituent with which the metal is combined.—A. G. L.

Electric furnace for metallurgical purposes. P. Girod, Ugine, France. U.S. Pat. 921,228, May 11, 1909.

XII.—FATTY OILS, FATS, WAXES,
AND SOAPS.

Catalytic actions of colloidal metals of the platinum group. Reduction of fats. C. Paal and K. Roth. Ber., 1909, 42, 1541—1553.

In a previous communication (this J., 1908, 864) the authors described the products obtained by the hydrogenisation of castor, olive, and cod-liver oils in the presence of colloidal palladium (see this J., 1904, 208). Only in exceptional cases was the iodine value of these and other fats reduced to *nil*; but on again treating the partially hydrogenised fats in the same way the reduction was, in most cases, complete. Not only were the unsaturated glycerides altered, but the unsaponifiable matter was also acted upon, and the hydrogenised fats no longer gave the characteristic colour reactions, or possessed the physiological properties of the original oils. They were also completely stable, and showed no rancid taste or odour after being kept for 6 months to a year in loosely closed vessels. The hydrogenisation in these later experiments was carried out in the manner described (*loc. cit.*), and it was found that preparations of colloidal palladium containing 46.1 and 61.7 per cent. of the metal proved equally effective. As was observed before, the amount of hydrogen absorbed was in all cases greater than the theoretical amount calculated from the iodine value, this being attributed by the authors to reduction of glycerides of hydroxy-fatty acids to ordinary glycerides, or of the latter to aldehydes, etc. *Castor oil* yielded a hard white crystalline mass softening at 78° C. and melting to a clear liquid at 81° C. The product was readily soluble in carbon bisulphide and hot chloroform, but only dissolved with difficulty in hot ether and alcohol. The iodine value, after two reductions, was *nil*. *Croton oil*, when completely reduced, yielded a hard reddish-brown fat melting at 49°—51° C., and having an iodine value of 0. It was readily soluble in carbon bisulphide and chloroform, but was somewhat less soluble than the original oil in alcohol. On cooling the alcoholic solution a crystalline deposit was obtained. The hydrogenised croton oil was completely devoid of the original burning taste, and was proved by physiological experiments to have no poisonous properties. *Olive oil* gave, after one reduction, a solid melting at 43°—47° C., and having an iodine value of 9. On complete hydrogenisation it yielded a soft crystalline mass softening at 61° C., and melting at 68.5° C. *Sesamé oil*, after two reductions, yielded a soft, white, almost tasteless solid, melting at 65°—69° C., and having an iodine value of 2. It gave a very faint reaction in Baudouin's test, but after standing for 8 months gave a much stronger reaction. This indicated a partial re-oxidation of the active substance in that test, although the fat itself had not altered. *Cottonseed oil*, after one reduction, yielded a yellowish-white solid melting at 56°—60° C., iodine value 1.9. After the second reduction it gave a hard, white, nearly tasteless, mass melting at 57°—60° C., and having an iodine value of *nil*. This product gave no reaction in Becchi's or Halphen's tests, even after standing for 10 months. *Linseed oil* gave a product with m. pt. 56°—63° C., and iodine value of 5.58; and this when again hydrogenised, yielded a hard white friable mass with iodine value *nil* and m. pt. 61°—65° C. *Butter fat* was in some cases completely hydrogenised in one reduction. The products were hard white friable fats which became soft at about 36° C., and melted at 44° C. (41°—42° C. in the case of another sample). They had a pleasant nutty flavour recalling that of cacao butter. They showed no signs of alteration after being kept for nine months. *Lard* yielded a hard, white, tallow-like mass, having an iodine value of *nil* and melting at 56°—60° C. The hydrogenised product was almost tasteless, and remained completely unaltered after being kept for 10 months in contact with air. It was readily soluble in carbon bisulphide and hot chloroform, but dissolved with difficulty in alcohol and ether. *Oleomargarine* derived from beef fat gave a quantitative yield of a white, nearly tasteless, crystalline fat, becoming

soft at 47° C., and melting at 55° C. It had an iodine value of 1.2, and behaved towards solvents in the same way as the product from lard.—C. A. M.

Enkabang and teglam fats and katio oil from Sarawak. C. J. Brooks, Analyst, 1909, 34, 205—208.

Enkabang fat is obtained from the seeds of *Shorea Glyberrima*, a large jungle tree belonging to the *Dipterocarpaceae*. In the Singapore market the seeds are termed *sinkawang*, and consist of three varieties of enkabang seeds. Owing to the fact that the fruit season only occurs once in three to five years the seeds are only exported at irregular intervals. For export they are decorticated and dried in the sun, and sold in admixture with teglam seeds. With these may also be mixed a similar seed containing no oil, which is bought by the Chinese for the purpose. The seeds should therefore be bought by Europeans on a basis of oil percentage. Air-dried samples examined by the author contained 31.2 per cent. of fat calculated on the weight of the nut and 46.7 per cent. on the weight of the kernel. The hot-pressed fat prepared by the Dyaks had a slight tallow-like odour and an agreeable taste, and was of a grayish-yellow colour. The following analytical values were obtained:—Sp. gr. at 100°/15.5° C., 0.851; m.pt., 35° to 43° C.; saponification value, 190.2; acid value, 24.7; iodine value, 30; and refractive index (Zeiss) at 40° C., 45.0 (n_D^{40} 1.4559). A sample extracted with carbon bisulphide, was of a yellow colour which was rapidly bleached on exposure to light, but the fat still gave a yellow oil when melted. It had a slightly rancid odour, and an unpleasant taste, and gave the following values:—Sp. gr. at 100°/15.5° C., 0.856; m.pt., 33° to 37° C.; free fatty acids, trace; saponification value, 190.8; iodine value, 30; refractive index (Zeiss) at 40° C., 46.1 (n_D^{40} at 40° C. = 1.4567); unsaponifiable matter, 0.3 per cent.; volatile fatty acids, 1.4 per cent.; Hehner value, 95.8. *Insoluble fatty acids*:—m.pt., 55.5° C.; solidification point, 53° C.; iodine value, 31; and mol. equivalent, 282.

Teglam fat closely resembles enkabang fat, but is prized more highly as a food, since it will keep in good condition for several years. It is expressed by the Dyaks from the seeds of *Isoptera Borneensis*. A sample of native preparation was of a pale yellowish-green colour, and had a sweet butter-like taste and a slight odour. It gave the following values:—Sp. gr. at 100°/15.5° C., 0.856; m.pt., 28° to 31° C.; acid value, 11.3; saponification value, 192.1; iodine value, 31.5; refractive index (Zeiss) 40° C., 45.2 (n_D^{40} at 40° C. = 1.4561); unsaponifiable matter, 0.5 per cent.; volatile fatty acids, 1.1 per cent.; Hehner value, 95.2. *Insoluble fatty acids*:—m.pt., 56° C.; solidification point, 51° C.; iodine value, 32.7; and mol. equivalent, 277.

Katio or kachiau oil is derived from the seeds of a species of *Bassia*, the kernels giving a yield of 47.5 per cent. (40 per cent. calculated on the whole seeds). The oil, which is used by the Dyaks for food, but is not exported, is of a bright yellow colour, and has a sweet taste, and an odour recalling that of almonds. It is a non-drying oil. A sample of native preparation gave the following values:—Sp. gr. at 15.5° C., 0.917; solidification point, 14° C.; acid value, 1.8; saponification value, 189.5; iodine value, 63.2; refractive index (Zeiss) 40° C., 53.4 (n_D^{40} at 40° C. = 1.4616); unsaponifiable matter, 0.41 per cent.; volatile fatty acids, 2.2 per cent.; Hehner value, 94.0. *Insoluble fatty acids*:—m.pt., 37.5; solidification point, 36° C.; iodine value, 62.5; and mol. equivalent, 185.—C. A. M.

Fat-hydrate, a constituent of kola-nuts. W. P. H. Van den Broek, and J. van Marrewijk. Pharm. Weekblad, 1909, 46, 346.—Cham. Zentr., 1909, 1, 1585.

20 c.c. of the oil were left in contact for 2 days at a constant temperature with 4 grms. of kola powder in presence of the absence of other substances. It was found that potassium ferrocyanide, salicylic acid, sodium carbonate, ether and petroleum ether had a favourable effect on the fat-hydrolysing action of the enzyme contained in the kola nut; uranyl nitrate, mercurous and mercuric chlorides, potassium chromate, bismuth nitrate,

oxalic, tartaric, and citric acids, alcohol, benzene, chloroform, and water acted injuriously, and potassium cyanide was without influence (compare Mastbaum, this J., 1907, 262). Experiments with "kola-red" showed that this is not identical with kola-lipase.

For the preparation of kolatin, the author recommends immersing the kola nuts for 3 minutes in aniline at 110° C. The nuts so treated yield a greyish-white powder from which kolatin can be easily isolated by the method of Goris (this J., 1908, 996).—A. S.

Cryoscopy of fats. Pailheret. See XVIII.A.

PATENTS.

Porcelain mould for paraffin or stearine candles. Mme. Lewy. Fr. Pat. 396,744, Oct. 27, 1908. Under Int. Conv., Oct. 28, 1907.

The mould, which may be used for the preparation of paraffin, paraffin-stearine, or stearine candles, consists of a porcelain tube or cylinder glazed on its interior surface.—W. P. S.

[Soap] *Emulsions; Process for the production of — and their use.* Crefelder Seifenfabrik Stockhausen und Traiser. Fr. Pat. 396,493, Oct. 5, 1908. Under Int. Conv., Oct. 8, 1907.

EMULSIONS for use in washing wool, etc., are prepared by dissolving 1 part of sodium soap (obtained by saponifying sulphonated fats or oils, oleic acid, etc., with 6 per cent. or more of sodium hydroxide) in 1.5 parts of water and adding from 1 to 2 parts of tetrachloroethane, pentachloroethane, trichloroethylene, or tetrachloroethylene. The mixture is emulsified thoroughly. Turkey-red oil or ordinary soap may be used in place of the sodium soap described above, and the solubility of the tetrachloroethane, etc., may be increased by the addition of a dilute solution of sodium hydroxide.—W. P. S.

Acid water produced in the decomposition of the soaps formed by the saponification of fats by means of metals or metallic oxides; Process for working up the —. J. Kellner. Ger. Pat. 208,806, Jan. 16, 1908.

The acid water is heated and treated with sodium carbonate or hydroxide in order to precipitate the carbonate, basic carbonate, or hydroxide of the metal used in the saponification process. The precipitate is separated by means of a filter-press and washed with water and steam. It is then ready for use as saponifying agent in the first stage of the process. The solution is neutralised with sulphuric acid, and evaporated until crystals of sodium sulphate separate; the mother liquor is crude glycerin containing only 1.5 to 1.6 per cent. of ash (sodium sulphate).—A. S.

Washing and bleaching; Preparation of a liquid product for —. F. Gallati-Grob. Fr. Pat. 396,721, Nov. 26, 1908.

SEE Eng. Pat. 23,725 of 1908; this J., 1909, 241.—T. F. B.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, &c.

(A.)—PIGMENTS, PAINTS.

Red lead; Physico-chemical and technical investigation of —. J. Milbauer. Chem.-Zeit., 1909, 33, 513—514; 522—523.

Is the author's experiments to determine the effect of varying the conditions in the production of red lead, litharge or pure lead oxide was heated in a rotatable reaction-tube in a furnace, a current of air or oxygen being meanwhile passed through the tube. The temperatures were measured by means of a pyrometer, precautions being taken to prevent contact of the thermoelements with the gases, and the amounts of red lead formed were determined by Töpf-Diehl's iodometric method (Z. anal. Chem., 1887, 296). Under the same

conditions of pressure, temperature, time, and speed of rotation of the tube, the yields of red lead from different quantities of material were practically identical. Thus 3.67, 7.6, and 11.6 grms. of pure lead oxide yielded respectively 17.9, 18.4, and 18.2 per cent. of red lead. The other conditions being kept constant, the quantity formed does not increase in direct proportion with the time, the formation being more rapid at first. Thus the following proportions of red lead were obtained in the respective times:—60 minutes, 4.5 per cent.; 120 minutes, 12.9; 180 minutes, 18.5; 270 minutes, 27.5; 375 minutes, 37.1; 420 minutes, 38.1; and 480 minutes, 43.5 per cent. An excess of oxygen has no influence on the reaction, but rapid introduction of the gas results in somewhat lower yields. With regard to the influence of the temperature, the following mean results were obtained in experiments in which all the other conditions (time, 3 hours; quantity of lead oxide, about 3.7 grms.; rotations, 75 per minute; velocity of current of oxygen, 80 c.c. in 2 minutes 25 seconds) were kept constant:—

Temperature.	Red lead.	Temperature.	Red lead.	Temperature.	Red lead.
°C.	Per cent.	°C.	Per cent.	°C.	Per cent.
240	0.6	380	8.9	450	18.1
310	0.7	390	10.1	470	19.1
320	1.8	418	15.0	500	20.2
350	4.7	430	17.3	550	20.9
360	7.1				

The products formed at temperatures of 320° to 450° C. were light or dark brown in colour, never red. Above 450° C., and with a time of 3 hours, red lead was invariably obtained. The partial pressure of the gases producing the reaction is a more important factor than the temperature. The following yields of red lead were obtained in experiments in which the lead oxide was acted upon for 3 hours at 480° C. by oxygen containing varying proportions of nitrogen, the speed of rotation and velocity of the current of gas being as before:—100 per cent. oxygen, 19.9 per cent. of red lead; 80 per cent. oxygen, 11.1 per cent. of red lead; 60 per cent. oxygen, 6.6 per cent. of red lead; 40 per cent. oxygen, 2.8 per cent. of red lead; and 20 per cent. oxygen, 0.3 per cent. of red lead. The proportion of moisture in the oxygen has no appreciable influence on the results.—C. A. M.

(B.)—RESINS, VARNISHES.

Shellac; New process of purifying — P. Singh. Chem. and Druggist, 1909, 74, 784.

THE author has found that, whereas both lac and lac-dye are soluble in ethyl alcohol, only the resin is dissolved by

wood spirit. He suggests that shellac should be purified on a commercial scale by a process based on this fact, and has found that the whole of the resin may be extracted from 100 lb. of crude lac in 3 to 4 hours in an apparatus made on the lines of Soxhlet's extractor. Samples thus prepared have been submitted to the U.S.A. Consul in Calcutta for trial in American factories, and are claimed to be equal to the best shellac in the market. A further suggestion is that shellac should be put on the market in the form of a coarse powder. This would obviate the cost of "stretching" the resin, to obtain the familiar "shell" form, and the necessity of adding rosin to lower the m. pt. to facilitate this process.—C. A. M.

Colophony; Contributions to the knowledge of American — I. The resin of the Norway pine. G. B. Frankforter. J. Amer. Chem. Soc., 1909, 31, 561—565.

THE resin used in the author's investigation was obtained by the ordinary method from the Norway pine, *Pinus resinosa*. It had a sp. gr. of 0.8137 at 20°/4° C.; a specific rotation of $[\alpha]_D^{20} = +4$; and a refractive index of 1.4788 at 20° C. The turpentine (about 20 per cent.) was removed by heating the resin *in vacuo*, and the residue was a white brittle solid (m. pt. 81.5° C.), which was very soluble in absolute alcohol, ether, chloroform, glacial acetic acid, acetone, benzene, toluene, and xylene; but was only slightly soluble in 70 per cent. alcohol, and quite insoluble in 60 per cent. alcohol. A crystalline substance could be obtained by dissolving the powdered residue in the smallest possible quantity of ether and pouring the solution into 80 per cent. alcohol. The crystals melted at 83.7° C., and contained 72.62 per cent. of carbon and 9.24 per cent. of hydrogen. They could be fractionated into two apparently distinct constituents by dissolving the dried powder in ether, cooling the solution in a freezing mixture and passing into it a current of anhydrous ammonia gas. A white crystalline powder was precipitated. This was found to be an unstable ammonium salt, melting at 98° C. to 112° C. (complete fusion) and having the composition, $C_{25}H_{36}O_5(NH_4)_2$. The liberated resin acid, purified by repeated precipitation from 80 per cent. alcohol, melted at 97° to 98° C., and had the composition, $C_{25}H_{38}O_5$. It differed from abietic acid, $C_{19}H_{30}O_2$, not only in composition, but also in physical and chemical properties. It yielded a barium salt, which was so unstable that it was decomposed by carbon dioxide, with the liberation of the acid. The ethereal filtrate from the ammonium salt was found to contain the ammonium salt of common abietic acid, though the m. pt. (129°—130° C.) of the recrystallised acid was somewhat lower than that previously recorded for abietic acid. In the author's opinion abietic acid or an isomeric acid is a constituent of most resins, whilst there is also probably present in each at least one distinct acid to which the resin owes its characteristic properties. This resin acid separated from the resin of the Norway pine differed from any such acid hitherto described, although in some respects it resembled Tschirch's palabietic acid.—C. A. M.

Scammony resin. F. O. Taylor. Amer. J. Pharm., 1909, 81, 105—111. Analyst, 1909, 34, 220—221.

SAMPLES of pure scammony resin, prepared from *Convolvulus scammonia*, and of the so-called "Mexican scammony," from the root of *Ipomoea Orizabensis*, were examined by the author, with the following results. The table also includes the figures obtained with samples believed to be mixtures of the two resins.

No.	Resin.	Yield of resin from root.	Moisture.	Ash.	Substances soluble in ether.	Acid value.	Saponification value.	Iodine value.
		Per cent.	Per cent.	Per cent.	Per cent.			
1	True scammony (?)	8.1	2.18	0.12	99.0	21.1	232.4	13.3
2	Mainly "Mexican scammony"	12.2	1.94	0.08	99.5	14.6	198.4	8.7
3	"Mexican scammony"	16.75	1.77	0.09	99.6	15.5	186.6	8.7
4	True scammony	7.93	1.71	0.05	99.7	15.6	238.1	10.8
5	do. do.	8.06	1.74	0.09	99.3	18.2	239.0	13.0
6	do. do.	7.71	1.86	0.09	99.3	18.8	240.5	14.3
7	do. do.	8.52	1.65	0.20	99.0	21.3	239.4	14.6
8	True scammony (?)	—	2.09	0.15	98.8	14.5	232.8	10.5
9	Mexican scammony	16.83	2.03	0.22	96.5	21.5	187.1	11.5

The saponification value thus appears to afford the best means of distinguishing between the two resins. According to the results of this test, samples 1 and 8 would seem to have contained a small proportion of "Mexican scammony." The root of the latter yields about twice as much resin as the genuine scammony.—C. A. M.

PATENT.

Shellac and lac-dye: Extraction of — [from stick-lac]. G. J. Fowler, Manchester, and E. J. O'Meara, Mirzapur, India. Eng. Pat. 12,877, June 16, 1908.

SHELLAC is soluble in cold alcohol or acetone, whereas the wax which accompanies it in stick-lac is not. In order to effect a separation, therefore, the stick-lac (100 lb.) is extracted either (1), with methylated spirit (15 to 20 gallons) at about 70° C., the residue being further treated with spirit (10 to 15 gallons) until extraction is complete; or, (2), with methylated spirit at the ordinary temperature. In the first case the alcoholic solution is allowed to cool and clarify, and is then distilled, the shellac being afterwards run off from the still and cast into convenient form. The residue in the extractor is next treated with a hot or cold solution of caustic soda of 0.2 to 1 per cent. strength, or with an equivalent solution of sodium carbonate, and the solution obtained is acidified with hydrochloric or sulphuric acid. The lac-dye is precipitated and may be filtered off, washed, and dried, and, if necessary, purified by re-solution and salting-out. When the cold extraction method is employed, the alcohol can be at once distilled off, and the shellac obtained as before. The wax is then extracted from the residue with hot methylated spirit, or with chloroform or carbon tetrachloride, and recovered from the solution by distillation. The lac-dye is obtained as in the hot extraction process. To obtain a pale-coloured shellac, the alcoholic solution is added to very dilute alkali; the shellac is precipitated, the small amount of dye present remaining dissolved in the aqueous liquid.—E. W. L.

(C).—INDIA-RUBBER, &c.

Rubber: Commercial analysis of manufactured — Pontio. Bull. Soc. Chim., 1909, 5 [9], 428—442.

A SPECIAL form of apparatus is described in which the various operations involved in the author's method of analysis may conveniently be carried out. This consists essentially of a large flask—capable of holding about 700 c.c. of solvent—surmounted by a second glass vessel of somewhat less capacity connected with it, at a constricted portion, by means of a ground glass joint. The apparatus is fitted with a reflux condenser. Digestions are carried out in the lower flask, lixiviations in the upper. *Free sulphur, resins, and paraffin wax* are estimated by determining the loss in weight suffered by the sample on digestion with absolute alcohol, and subsequent lixiviation with the same solvent. *Substitutes, with their combined sulphur* are estimated in a similar manner from the loss in weight suffered by the alcohol extracted sample on digestion with an 8 per cent. solution of sodium hydroxide in 95 per cent. alcohol. *Asphaltum, bitumen, mineral oils, and tar* are found by the loss in weight on extraction of the same sample with a mixture of 40 parts of oil of lavender and 60 parts of acetone. *Caoutchouc and combined sulphur, as well as remaining organic and inorganic constituents* are determined by extraction with cumene (this J., 1909, 431). *Free sulphur* is determined by a separate extraction of a 2-grm. sample with absolute alcohol, oxidation of the extract with a mixture of 10 c.c. of soda lye of 36° B. and 20 c.c. of hydrogen peroxide (12 volumes), evaporation to dryness and moderate calcination, and precipitation from the acidified solution of the residue by means of barium chloride. *Sulphur in substitutes* is determined in the same sample by subsequently extracting with alcoholic soda, and oxidising the extract as in the case of free sulphur. *Sulphur in minerals* is determined in the residue from the cumene extraction by fusion with a mixture of equal parts of sodium and potassium carbonates, in the ordinary way. *Total sulphur* is determined in the original sample by the manganese dioxide method (this J., 1909, 431). *Sulphur of vulcani-*

sation is estimated by difference. *Moisture* is determined by drying at 115—120° C., preferably in an atmosphere of carbon dioxide. In the analysis of manufactured gutta-percha the following determinations are made:—*Resins* by loss of weight on digestion with 96 per cent. alcohol for about 12 hours. *Bituminous matters*, by extraction with ether, which dissolves about 38 per cent. of ordinary asphaltum, and subsequently with carbon bisulphide or toluene, in which the remaining 62 per cent. is soluble. *Gutta and remaining ingredients* are separated by means of cumene as in the case of vulcanised rubber, or the gutta may be determined direct, by dissolving the acetone-extracted sample in boiling ether, filtering, concentrating, and precipitating the gutta by pouring into hot alcohol, dissolving again in ether and reprecipitating.—E. W. L.

Rubber goods: Determination of vermilion [mercuric sulphide] and of "golden sulphide" [antimony sulphide] in — F. Frank and D. Jacobsohn. Gummi Zeit., 1909, 23, 1046—1047.

THE sample, cut up into small pieces, is oxidised, as in the estimation of sulphur, by a double evaporation with nitric acid. Potassium chlorate is then carefully added, and evaporation with nitric acid on the water-bath repeated several times. Finally the nitric acid is driven off by evaporation with hydrochloric acid, the residue taken up with hydrochloric acid, and filtered hot, after dilution with water. If, at this stage, unoxidised organic material renders filtration difficult, the sample should be oxidised by repeated heating with fuming nitric acid and potassium chlorate in an Erlenmeyer flask. This is not generally necessary. Insoluble mineral constituents (silicates and barium sulphate) remain on the filter and are determined by incineration. The antimony and mercury are precipitated from the hot filtrate—after most of the acid has been driven off, and, advisably, a considerable quantity of ammonium chloride added to assist precipitation—by means of sulphuretted hydrogen. The mixed sulphides are collected on a weighed filter, or Gooch crucible, washed with alcohol, ether, carbon bisulphide, and ether, to remove free sulphur, dried, and weighed. The antimony sulphide is then removed by means of ammonium sulphide, and the mercury sulphide washed as before, dried, and weighed. To confirm the result obtained, the antimony in the filtrate may be converted into tetroxide, by evaporation and oxidation with nitric acid, and weighed as such. Other mineral constituents are estimated in the usual way in the filtrate from the mixed sulphides.—E. W. L.

Raw rubber: Purification of — and recovery of the solvents employed. A. Joly. Fr. Pat. 396,300, Oct. 31, 1908.

THE resins and other soluble impurities are removed by treating the rubber, in a suitable state of division, with mixtures of acetone, methyl alcohol, and ethyl alcohol with the ordinary rubber solvents, or with crude or rectified wood-spirit, excise methyl alcohol ("méthylène rigé"), or mixtures of these with ethyl alcohol, or acetone and ethyl alcohol, and the solvent is recovered by distillation.—E. W. L.

Rubber: Process and apparatus for vulcanisation of — M. Lamy. Fr. Pat. 396,620, Jan. 30, 1908.

THE unvulcanised rubber sheet, or rubber-coated fabric is wound on a drum, either alone, or in alternate layers with a thin sheet of metal, and the whole is placed in an autoclave, into which an inert gas, e.g., carbon dioxide or nitrogen, is then introduced under pressure. The autoclave is in its turn enclosed in a heater, which may be either a hot-air stove or a second autoclave heated by steam. Means are provided for rotating the inner autoclave within its jacket, in order to avoid irregular heating. The process is particularly applicable to the vulcanisation of rubber-coated fabrics, which might be damaged by vulcanisation in open steam or by means of sulphur chloride, and which cannot be cured in hot air in the ordinary way on account of the absence from the mixing of facilitating agents such as litharge.—E. W. L.

Elastic mass resembling rubber. K. Lengfellner. Fr. Pat. 396,814, Nov. 27, 1908. Under Int. Conv., Nov. 29, 1907.

THE following compositions are claimed:—(1), a mixture of celluloid, nitrocellulose, and cellulose (e.g., powdered cork); (2), a mixture of rubber with celluloid or nitrocellulose, or with both celluloid and nitrocellulose; (3), a mixture of rubber and cellulose (particularly powdered cork) with celluloid or nitrocellulose, or with both celluloid and nitrocellulose. The superposition of these various mixtures in layers, to form solid tyres, as well as the heels, soles, and other portions of shoes, is also claimed.—E. W. L.

Rubber; Process and apparatus for the separation of — from resin in latex and resinous products whether natural or not, containing rubber. G. F. Flamant and L. G. Worms, Paris. Eng. Pat. 20,896, Oct. 3, 1908. Under Int. Conv., Oct. 4, 1907.

XIV.—TANNING, LEATHER, GLUE, SIZE.

Tanning materials; Determination of water in —. J. Jedlicka. Collegium, 1909, 162—164.

THE author has made experiments with a method published by Thörner and also by Schwalbe (this J., 1908, 94) for the estimation of water, by distillation of the material with petroleum having a higher boiling point than water. The distillation flask employed, was a glass one surrounded by copper to prevent breakage, and the receiver, a measuring cylinder kept cool by immersion in cold water. The method was applied to the estimation of water in fresh and leached-out oakwood, blood albumin, and liquid extracts and a table is given showing good concordance between results obtained by the distillation method and those obtained by the official gravimetric method. In the case of liquid extracts, however, the distillation process gave results about 2 per cent. higher than the official. Correction can be made for the small quantity of water suspended in the petroleum, but this is generally negligible, 15 c.c. of petroleum being found to contain only 0.05—0.1 c.c. of water.—S. H.

Belting leather; Determination of the tensile strength of —. J. Paessler. Collegium, 1909, 45—52, 53—57, 62—68, 69—88, 95—100, 103—109.

MINIMUM resistance to tearing of 3 kilos. per 1 square mm. cross-section is generally required in belting leather. The test-piece used by the author consisted of a strip of leather 30 mm. wide and 100 mm. long, with an extension at either end of 40 mm. width and 50 mm. length which was clamped in the machine. It was found that pieces taken from different parts of a hide gave very different results. Previous work by Bach and Rudeloff also pointed to this fact and the latter investigator showed that variation of moisture also influenced the results, and recommended that for comparative work, leather should be kept in a room of constant humidity for a period of 7 days. This precaution was taken in these experiments. 8 different samples of belting leather, representing different grades and different degrees and methods of stuffing, were examined. Strips were taken from several places on each leather at measured distances from the middle of the back, in all 12 samples from each. Strips taken from the neck, in practically all cases showed greater resistance than those from the tail end of the butt, the respective resistances being 3.19 kilos. and 2.65 kilos., which fact is in accordance with results obtained by Bach. Further experiments on samples taken down the middle of the back showed that the greatest resistance was obtained in strips taken midway between the neck and the tail end of butt. To test the resistance to tearing, test pieces of leather clamped at one end only and having

a round hole of 6 mm. diameter near the other end, were used. A pin of the same size was passed through the hole and the strain applied. It was found that for all leathers, results varied very little and were always lower than the breaking resistance. Measurements were also made of the stretching shown by different leathers during the breaking test, and it was found that generally if the resistance was higher so was the stretching. The stretching was similar in strips taken from the neck and tail ends of the butt, but varied according to the distance from the middle line of the back. A table is given comparing results obtained in leathers of: (1), pit tannage; (2), mixed tannage; (3), drum tannage. While the average breaking resistance was greatest in the drum-tanned leathers, the tearing resistance and stretching were highest in the pit-tanned specimens, while in the mixed tannage, the breaking resistance was lower than in the other two, and the tearing resistance and stretching results were intermediate between those for pit and drum tannage. A large number of tables of results accompanies the article.—S. H.

PATENTS.

Casting plastic masses; Process for —. G. S. A. Appelquist. Ger. Pat. 208,764, Sep. 13, 1906.

It has been almost impossible hitherto to prepare moulded articles by casting from plastic masses prepared from glue, hygroscopic substances (glycerin, calcium chloride, etc.), and chromates or other oxidising agents, since under the influence of light, the masses set so rapidly that it was not possible to completely fill the mould. Even when moulded articles of simple shape are prepared by casting, the outer surface becomes hard and brittle, whilst the interior remains soft. In order to overcome this difficulty, it is proposed, according to the present patent, to add to the mass before casting and before or simultaneously with the chromate, one or more colouring matters or coloured substances of a black, red, blue, or yellow colour. By this means the hardening of the mass under the influence of light is retarded.—A. S.

Potassium in soils; Rapid method for the determination of total —. O. M. Shedd. J. Ind. and Eng. Chem., 1909, 1, 302—304.

THE process recommended by the author is a combination of two known methods. The potassium is brought into solution by the method of J. L. Smith (see Fresenius' "Quantitative Analysis," Amer. Edit., p. 426; also Crookes' "Select Methods in Chem. Analysis," 3rd Edit., pp. 26—39), and is then determined by the cobaltinitrite method of Drusel (this J., 1907, 1256).—A. S.

Potash in commercial fertilisers; Loss of —. F. B. Porter and E. G. Kenny. J. Ind. and Eng. Chem., 1909, 1, 304—307.

WHEN water-soluble potassium compounds are added to commercial fertilisers, there is an apparent loss of water-soluble potash when this is subsequently determined by the method of the Amer. Assoc. of Agricultural Chemists. This is due to the fact that acid phosphate has the power of withdrawing certain soluble compounds from solution. The authors' experiments show that acid phosphates of different ages and from different kinds of rock all exhibit practically the same activity in this respect. The amount of potash withdrawn from solution increases with the proportions of potassium compounds and of acid phosphate present. Part of the apparent loss of potash is also due to retention by the precipitate produced by ammonia and ammonium oxalate in the analysis. "No. 1 tannage" has no tendency to retain potash itself and partially prevents the retention of potash by acid phosphate. From experiments in which the insoluble residue containing the retained potash

was treated with neutral ammonium citrate solution, citric acid solution, and water respectively, the authors conclude that about 25 per cent. of the retained potash is dissolved on the first contact with rain water, and about 56 per cent. on the first contact with soil water.

—A. S.

Phosphoric acid; Gravimetric molybdate method for the determination of — for the international trade of raw phosphates. Ullmann. Proposed at the VII Int. Cong. of Applied Chem., London, May 26, 1909.

THE following reagents and solutions are required:— (1). *Aqua regia*: 3 parts of hydrochloric acid of sp. gr. 1.12 mixed with one part of nitric acid of sp. gr. 1.2. (2). *Ammonium molybdate solution*: 150 grms. of ammonium molybdate are dissolved in 500 c.c. of hot water and the solution is mixed with 400 grms. of ammonium nitrate also dissolved in water, the mixture being then diluted to 1 litre; this solution is added to 1 litre of nitric acid of sp. gr. 1.2, the whole is allowed to stand for 12 hours at a temperature of 60° C. (or for 24 hours at the ordinary temperature), and then filtered. (3). *Solution for washing the molybdate precipitate*: 32 parts of nitric acid of sp. gr. 1.2 and 50 grms. of ammonium nitrate (free from phosphate) are diluted to 1 litre with water. (4). *2.5 per cent. ammonia solution*. (5). *Neutral magnesia solution*: 50 grms. of magnesium chloride ($MgCl_2 \cdot 12H_2O$) and 150 grms. of ammonium chloride are dissolved in 1 litre of water.

Method. Five grms. of the sample are treated in a 500 c.c. flask with 50 c.c. of *aqua regia* and the mixture is evaporated to the consistence of a syrup in order to eliminate silica. The residue, which when cold is almost solid, is boiled with a mixture of 10 c.c. of nitric acid of sp. gr. 1.2 and 50 c.c. of water, cooled, diluted to a volume of 500 c.c. and filtered. Fifty c.c. of the filtrate (equivalent to 0.5 gm. of the substance) are mixed with a sufficient quantity of the molybdate solution (at least 100 c.c. of the latter for each 0.1 gm. of phosphoric anhydride present) and kept at a temperature of 50° C. for 1 hour. The precipitate is then collected on a small filter and the filtrate is treated with a further quantity of molybdate solution and allowed to stand for 12 hours at 60° C. in order to ascertain whether all the phosphoric acid has been precipitated. The precipitate is washed with the acid ammonium nitrate solution until the filtrate is free from calcium salts, at least five washings, using 20 c.c. each time, being necessary. The test for calcium is made by adding a little sulphuric acid and 2 c.c. of alcohol to 1 c.c. of the wash-water; the mixture remains clear in the absence of calcium salts. The yellow precipitate is then dissolved in about 80–100 c.c. of 2.5 per cent. ammonia and the filter is washed five or six times with hot water; the volume of the solution and washings should not exceed 150 c.c. The solution is heated to between 60 and 80° C., and the phosphoric acid is precipitated by the addition, to the hot solution, of 20 c.c. of neutral magnesia solution, drop by drop and with constant stirring. At the end of 4 hours the precipitate is collected on a filter and washed with 2.5 per cent. ammonia until free from chlorine. The filter and precipitate are then heated in a platinum crucible until the filter is charred completely, (care being taken that no flame is produced during the ignition of the filter) and the ignition is continued over a blast lamp until the weight is constant. The ignited residue should be quite white.

Factors.—From $Mg_3P_2O_8$ to P_2O_5 , 0.63780; from P_2O_5 to $Ca_3P_2O_8$, 2.185.—W. P. S.

Consumption of sodium nitrate in U.S.A. Munroe. See VII.

XVI.—SUGAR, STARCH, GUM, &c.

Juice [Sugar]; Quantities of non-sugar precipitated from raw — by defecation and saturation, and the examination of saturation muds. H. Claassen. Ver. dent. Zuckerind., 1909, 385–402.

THE author points out that the calculation of the amount of non-sugar precipitated from the raw juice and carried away with the saturation mud, from the purities of the raw and thin juices, gives inaccurate results, and that the amount can only be determined from the weight and composition of the mud. The percentage of organic non-sugar in the mud is best determined by deducting the percentages of water, carbon dioxide, and sugar, from the percentage loss on ignition. The quantity of inorganic non-sugar withdrawn from the raw juice and carried away with the mud is small in comparison with the quantity of organic non-sugar, and an average value of 0.17 per cent. of the weight of beetroots may be assumed to represent it without involving appreciable error. In factories in which similar methods of working are used the total non-sugar precipitated from the raw juice does not vary much; with employment of normal quantities of lime, it ranges between 0.8 and 1.1 parts per 100 parts of beetroots. The quantity of organic non-sugar precipitated, increases with the quantity of lime used, from about 0.6 per cent. with 1.2 per cent. of lime to 0.8 per cent. with 2–2.5 per cent. of lime, per 100 parts of beetroots. The quantity of the lime in the mud which is combined with non-sugar substances, varies with the quantity of lime used; thus, with additions of 1.2 and 2.5 per cent. of lime, the percentages of lime combined with non-sugar in the mud were found to be 0.34 and 0.57 respectively. Hence in the more complete defecation and saturation, a larger quantity of organic matter is converted into insoluble lime compounds. The author also shows that if, in the diffusion process, all the diffusion water is returned to the battery, the calculated loss of dry substance in working (i.e., the difference between the dry substance-contents of the beetroots and the sum of the dry substance-contents of the products) is practically identical with that found from analysis of the mud.—L. E.

Sugar; Application of temperature corrections to the polarisation of raw — and other products with the quartz-wedge saccharimeter. C. A. Browne. Z. Ver. dent. Zuckerind., 1909, 404–431.

SEVERAL workers have shown that the polarisation of a normal solution of pure sucrose in quartz-wedge compensation saccharimeters, decreases by about 0.03° V. per 1° C. rise of temperature, and, in 1897, the U.S. Treasury Department adopted a method, depending on the employment of a standardised quartz-plate, for correcting the influence of temperature on the polarisation of imported and dutiable sugars. As a result of the litigation which ensued, the decision of the Treasury Department was finally upheld (see this J., 1903, 721; 1904, 806; 1905, 217). The author points out, however, that the temperature corrections for pure sucrose are not always valid for raw sugars, molasses, etc. He has made experiments on the influence of temperature on the polarisation of: (1), mixtures of sucrose and cane molasses in varying proportions; (2), commercial cane sugars

conversions were effected by diastase precipitated from the aqueous extract of a well-grown malt rich in protein by the addition of ammonium sulphate; the concentration of the starch varied from 1 to 5 per cent. One gram of starch is found to correspond with 4 divisions on the refractometer scale. The following method is given for the determination of starch in cereals. 2—3 grms. of the finely-powdered material are pounded in a mortar with a small quantity of water and introduced quantitatively into a 100 c.c. flask, the volume being made up to about 80 c.c. 0.2 c.c. of a 1 per cent. solution of diastase is then added and the flask heated for 5 minutes in a boiling water bath and then cooled to the ordinary temperature. After the addition of a further quantity of 0.2—0.3 c.c. of the 1 per cent. diastase solution, the flask is kept at 55°—60° C. for half an hour, after which it is cooled and the liquid made up to 100 c.c., well shaken, filtered and the filtrate examined in the refractometer at 17.5° C. To correct for the refraction of the soluble constituents of the cereal, 2—3 grms. of the latter are finely powdered, pounded in a mortar with a little water, the whole being then introduced into a 100 c.c. flask and the volume made up to 100 c.c. After being well shaken, the liquid is filtered and its refraction determined at 17.5° C. With cereals like rye, which contain a large proportion of diastatic enzymes, the cold water extract should not be allowed to stand for long. Measurements of the proportions of starch in a number of different cereals show that this method gives results in close agreement with those obtained by the polarimetric method (compare Lintner, this J., 1907, 281), the greatest difference found being 0.37 per cent.—T. H. P.

Manihot [Tapioca] root as a raw material for spirit and yeast manufacture. H. Lange. Z. Spiritusind., 1909, 32, 200—201.

THE fresh cassava, manihot or tapioca root has already been investigated from the point of view of spirit manufacture; when saccharified by malt it has about double the spirit-value of fresh potatoes. The fresh roots can, however, only be worked in the countries where they are grown; in the European distillery the dried roots would have to be employed. An analysis of these showed: Water, 14.00; starch-value (Maerker), 66.89, (polarimetric), 67.40; protein, 2.06; sugar (as invert sugar), 1.90 per cent. They are therefore richer in starch than maize or rye, and about equal to dried potatoes. The dried roots cannot be saccharified in the form in which they are received, even by prolonged steeping and steaming under high pressure; some form of preliminary disintegration is essential. The pieces of root are best broken up in a ball-mill and then ground in a Gruson mill. For high-pressure steaming, it is sufficient to reduce them to the form of coarse grist, but for an open boil they must be ground to a meal. The best results are obtained in a Henze steamer, 100 kilos. of grist and 250 litres of water being steamed for one hour under atmospheric pressure and for one hour under pressure gradually increased up to 2.25 atmospheres, lastly for 10 minutes at 2.5 atmospheres. The mash is saccharified with 10 per cent. of long-grown green malt. Starting at a density of 19.65° Balling and an acidity of 0.1°, the mash is fermented by distillery yeast, Race XII. Attenuation proceeds normally with a pitching temperature of 20° C., and reaches —0.8° Balling after 60 hours. The yield of alcohol corresponds to 59.8 "litres per cent." on the starch employed, which is very satisfactory. The spirit contains no trace of hydrocyanic acid, which occurs in the spirit prepared from the fresh roots. An analysis of the dry substance of the spent wash showed:—protein, 16.97; fat, 3.86; non-nitrogenous extractives, 3.86; crude fibre, 12.24; ash, 11.03 per cent. Compared with the spent wash from maize mash, it is deficient in protein and fat, and possesses only about two-thirds the nutrient value of the latter; the crude spent wash is also more dilute. For the manufacture of pressed yeast, manihot mash gives normal results and yields; the character of the yeast resembles that prepared from maize more closely than that obtained from potato mash.—J. F. B.

Hop tannin. II. A. C. Chapman. J. Inst. Brewing, 1909, 15, 360—369.

IN a previous paper the author described a method for the estimation of tannin in hops, based on the precipitation of a sparingly soluble cinchonine compound. This compound was stated to contain approximately 4 per cent. of nitrogen, corresponding to 60 per cent. of tannin. The compound is, however, not easily oxidised in the Kjeldahl process, and more careful determinations of the nitrogen by the Dumas method have shown that the product contains 4.3 per cent., corresponding to 54.9 per cent. of tannin. The more correct factor for the tannin would therefore be 0.55, in the case of hop-tannin. In the case of gallotannic acid, the compound contains only 3.45 per cent. of nitrogen, corresponding to 63.8 per cent. of tannic acid. The author has found that the tannin-content of hops does not diminish during storage, as was previously supposed; the statements to that effect are based on Löwenthal's method, which does not appear to be reliable in the case of hop-tannin. This observation of course applies only to normal conditions of storage, at moderately warm temperatures, with and without exposure to air; if the hops were allowed to become moist it is conceivable that tannin might disappear as the result of bacterial activity or other agencies. The author has endeavoured to trace some connection between the brewing value or general quality of the hops and their tannin-content. He has found, however, that, whereas the quality of the hops certainly appears to be related to the resin-contents, the percentage of tannin appears to have no influence. When an infusion of hops is added to a boiled and filtered wort, a precipitate is formed, which re-dissolves on boiling and separates again, in a very finely divided form, on cooling. The quantity of nitrogenous matter removed from a boiled wort by the addition of a hop infusion in the cold only amounts to 3.7—4.3 per cent. of the total nitrogen of the wort. Gallotannic acid, on the other hand, is capable of producing a copious precipitate in malt worts to which an excess of hop infusion has been added. From the behaviour of malt worts towards hop tannin and gallotannic acid respectively, the author concludes that the matters which are precipitated belong to the class of albumoses. Finally, the author considers that the tannin of hops plays a far less important part in the brewing process than has usually been assigned to it, and that it is a constituent possessing little practical significance.

—J. F. B.

Oxidising enzymes: Properties and classification of —
B. Moore and E. Whitley. Biochem. J., 1909, 4, 136—167.

OXIDISING enzymes may be divided into two broad groups: the tyrosinases of Bertrand, the distribution of which is limited, and the peroxidases of Bach and Chodat, which are very widely distributed in organic tissues, and possess the property of colouring guaiacum tincture blue in presence of a peroxide. Bach and Chodat (this J., 1903, 384) state that the oxidising enzymes of plant juices may be split up into two portions: "oxygenase," which is inactive in the absence of the second fraction, and "peroxydase," which is inactive in absence of oxygenase or a peroxide. Some confusion has existed as to the precise definition given by Bach and Chodat of the nature of oxygenase; some authors assume that it was defined as an unstable organic peroxide, whilst others understand that it was regarded as a true enzyme, capable of producing a peroxide from constituents of the juice on exposure to atmospheric oxygen. The authors claim that Bach and Chodat have consistently enunciated the latter view, and that this view is incorrect, since no evidence of the enzymic nature of oxygenase exists. The authors hold that only one type of oxidising enzyme occurs in the kind of plant juice under consideration, the peroxydase, which are active only in presence of a peroxide. In those juices, which apparently contain an oxygenase and produce a blue coloration in guaiacum tincture directly a peroxide is already present, and, so far from this being produced on exposure to air, it is rapidly destroyed under those conditions, as is also hydrogen peroxide if added.

very small quantities. This destruction is due partly to reduction and partly to the action of the "catalase," which again is incorrectly regarded by Bach and Chodat as an enzyme. Guaiacum tincture gives somewhat erratic results with these plant juices, and there was an impression that, whereas an "old" tincture is frequently turned blue by a peroxidase alone, a freshly prepared tincture is only coloured blue in presence of a peroxide, whether already present or added. The authors show that this peculiarity has nothing to do with the age of the tincture, but depends on traces of peroxide introduced by the presence of tissue impurities in the resin employed. When, therefore, a vegetable juice colours guaiacum blue without the addition of a peroxide, the phenomenon is due to the presence of a peroxide, either in the juice itself or in the resin from which the guaiacum tincture was made. These adventitious peroxides are readily destroyed by heat; they may also be eliminated by treating both the juice and the tincture with animal charcoal, after which no juice possesses the property of colouring guaiacum blue unless a peroxide be added. In this way the reactions observed with guaiacum are brought into line with the other colour reactions of the combination—peroxidase + peroxide—with substances such as *p*-phenylenediamine, α -naphthol, etc., which can contain no pre-formed peroxide so far as the tinctures are concerned. The fact remains, however, that the active constituent of guaiacum resin, guaiaconic acid, is more readily oxidisable than these other bodies, and will sometimes show positive results when the latter do not.

Parallelism between hydrolytic enzymes, oxidising enzymes, and active bodies developed in immune sera. The above observations appear to show that the whole difference between the various juices, and other fluids showing an oxidising action, consists in the presence of a variable, small amount of pre-formed, unstable peroxide. There is only one enzyme or type of enzyme concerned, *viz.* peroxidase. Thus these actions may be linked with other ferment actions, all depending on three factors, as sketched in the table below:—

Ferment action.	Substratum.	Combining body.	Catalyst.
Hydrolytic.	Proteins, carbohydrates, fats.	Elements of water with intermediary action of acids or alkalis.	Pepsin, trypsin, diastase, zymase, lipase.
Oxidising.	Tyrosine, phenols, chromogenic indicators.	Oxygen derived from peroxides.	Tyrosinase, peroxidase.
Immunising.	Bacteria, toxic substances.	"Complement" or thermo-labile constituent of serum.	Specific anti-toxin.

The substratum and catalyst have specific relationships within certain narrow limits of molecular configuration, but the combining body is more general, within the limits of type; in many cases it is unstable, but its loss may be more easily replaced.—J. F. B.

Change in composition of unground cereals during storage.

PATENTS.

Yeasts; Process and apparatus for separating inferior yeasts from normal —. O. Selg and C. Gmtrum.
Fr. Pat. 396,869, Nov. 28, 1908.

THIS invention depends on the observation that pure and secondary yeasts are respectively heavier and lighter than water. The apparatus includes an upper and a lower vessel connected by a neck. Water is introduced at the bottom of the lower vessel, and when the upper vessel is partly filled, the yeast to be treated is introduced into it. Admission of water is continued until the upper vessel is nearly filled. A tube, open at its lower end, closed at its upper end by a conical cap, and perforated near its upper end, is now placed in the upper vessel; it is supported by a cross-piece resting on the conical bottom of the upper vessel. The lower end of the tube projects through the neck connecting the vessels, the perforations near the

upper end of the tube being below the surface of the water in the upper vessel, whilst the conical cap is above the surface of the water. The pure yeast slowly descends into the lower vessel, the water thus displaced rising through the tube into the upper vessel, and carrying with it any of the lighter yeast which may have settled with the heavier yeast. After about half an hour, the tube is inverted and its conical cap now closes the neck between the vessels. The pure yeast is then withdrawn from the bottom of the lower vessel.—L. E.

Vinasses; Process for treating distillery —. F. and E. D. Verbière. Fr. Pat. 396,288, Jan. 21, 1908.

THE vinasse is treated, first with a clarifying agent such as ferric chloride or aluminium sulphate, and then with lime, preferably in the form of milk of lime, whereby the metallic oxide of the clarifying agent, suspended matter, phosphoric acid, a large part of the organic nitrogenous matter, certain acids, and organic substances, are precipitated. The amount of lime added must be just sufficient to effect complete precipitation. The precipitate is separated in the form of cakes by means of filter-presses. The cakes may be dried, preferably in a continuous tunnel drying apparatus heated by hot air or steam. The dried cakes are powdered and, if desired, may be mixed with certain fertilisers such as potassium sulphate, ammonium sulphate, phosphates or superphosphates, nitrates, etc., in order to obtain complete fertilisers. On the other hand, the cakes may be submitted to processes whereby certain constituents, *e.g.*, oxalic acid, are removed. A certain proportion of the filter-press residues from the sugar-house may be added, either at the initial stage of manufacture as a substitute for the lime, or at the drying stage.—L. E.

Alcoholometers and the like. P. Desq, Argenteuil, France.
Eng. Pat. 9293, April 29, 1908.

THE author has devised an alcoholometric thermo-

differential meter, giving on one and the same dial the indications of temperature, alcoholic strength, and quantity of the liquid measured as a function of the temperature, and the quantity of absolute alcohol contained in the said measured liquid. It consists of a thermo-regulator acting in combination with two alternative measuring devices or vessels which determine exactly the real volume of the liquid measured with reference to its temperature, the said measuring devices being provided with distributors and check valves automatically operating under the action of floats which act on a reversing device with weight connected to distributors and valves. The measured liquid is discharged on to the movable plate of a balance-aerometer working in connection with floats in a bath of mercury, the movements of which are in direct proportion to the quantity of alcohol contained in the said liquid; these movements are indicated on a dial by means of a mechanism with differential movements, submitted to the simultaneous action of the recording parts for the measurement and the weighing, for the purpose of determining the volume of absolute alcohol contained in the liquid.—T. H. P.

(I.)—FOODS.

Cereals; Change in the composition of unground — during storage. S. Leavitt and J. A. Le Clerc. J. Ind. and Eng. Chem., 1909, 1, 299–302.

THE authors studied the changes which take place in maize, barley, rye, wheat, and oats when these are stored for long periods in their natural (unground) condition. It was found that in the course of two years there was more or less change in all cases, but the changes took place much less rapidly in the unground cereals than in the flours produced from them. The changes took place chiefly in the sugar-content and then in the proportions of proteins soluble in 70 per cent. alcohol, proteins soluble in 5 per cent. potassium sulphate solution, and soluble proteins coagulated by Stutzer's reagent (cupric hydroxide). Maize, barley, and oats were most susceptible to loss of sugar. Unground maize lost about 60 per cent. of its total sugar in 1 year. In the case of wheat, on the other hand, many samples showed a slight loss in the first year and then a rapid gain; in some instances a gain of 24 per cent. of the total sugars present was noted at the end of two years. Maize was also the cereal most susceptible to protein change.—A. S.

Fungus on chilled beef. Klein. Times, May 21, 1909. [T.R.]

IN the course of a report on the nature of brown spots on chilled beef, the author states that the meat arrives in England as "chilled beef" (hind quarters) from the Argentine. Portions of it are often more or less covered with brown spots. Such meat is regularly rejected, at any rate at Liverpool, by the meat inspectors, although the deeper parts of the fat and flesh are apparently normal. An enormous waste is caused by this rejection. The spots are of a light brown, varying in size, from a pin's head to about one-eighth of an inch in diameter, and are, in places, so abundant as to form confluent patches. They are not on the free surface, but are, as a rule, embedded in the superficial part of the subjacent layer of fat, and do not extend deeper than one-twelfth to one-sixteenth of an inch. They are a species of yeast belonging to the *Saccharomyces* group. They are probably derived from water, air, or excremental matter, and are pressed into the meat. There is no justification for suggesting that they are derived from the inside and have been present in the animal itself. The infection takes place before the carcase is placed on the ship. Dr. Klein suggests the sterilisation of the stockinette material in which the meat is wrapped; the use of boiled or condensed water in wiping the meat while dressing it; the uniform circulation of dried air of the requisite low temperature in the chilling rooms; and the separation of the meat, one quarter from another, on the ship. The fungus is harmless for the animal body, and apart from the unsightliness there is no necessity to condemn as unfit for food a large portion of the quarter of which only the superficial part is affected with the brown spots. The removal of the most superficial layer of the fat would fully meet all objection. Therefore it is hoped that some modification may be made in the regulations regarding the condemnation of meat thus spotted.

Fats, in particular butter and margarine; Cryoscopy of —. F. Pailheret. Bull. Soc. Chim., 1909, 5, 425–428.

FOR pure butters, the coefficient of depression of freezing-point in benzene varies with the concentration, but is constant between concentrations of 18 and 22 per cent. In this region, the coefficients of more than 120 samples of butter, of very diverse origins, agreed very closely, the mean value being 0.0885. The freezing-points for equal concentrations of different samples were never found to differ by more than 1/200 °C. from the mean. Margarines give concentration-depression curves which

show a general similarity to, but which are not coincident with the butter curves. The steady value of the coefficient of depression for margarine, at concentrations between 18 and 20 per cent., was found to be 0.0764. The presence of 5 or 6 per cent. of margarine in butter can be detected by the application of this method, but the cryoscopic results should generally be supplemented by the determination of other constants, in order to ensure detection of skilful adulteration with both margarine and coconut oil simultaneously.—E. W. L.

Furfurals; Determination of — in presence of pentosans. [Detection of husks in cacao powder]. D. H. Brauns. Pharm. Weekblad, 1909, 46, 326–331. Chem. Zentr., 1909, 1, 1608–1609.

THE plant constituents which yield furfural on distillation with acid and which are known generally as pentosans, may be divided into two groups, namely "pentosans," which yield furfural on boiling with very dilute (2 per cent.) acid, and "furfurals," which are decomposed only by strong acid. Experiments showed that cacao powder contains practically no furfurals, whereas cacao husks contain 1–2 per cent., and adulteration of the former with the latter may therefore be recognised by means of determinations of pentosans and furfurals.—A. S.

Chocolate; Composition and analysis of —. N. P. Booth C. H. Cribb, and P. A. E. Richards. Analyst, 1909, 34, 134–148.

AS chocolate may be adulterated by the addition of cacao husk, cacao-butter substitutes, starch, and colouring matters, the authors suggest that the following determinations should be made in order to detect and ascertain the amount of adulteration:—moisture, mineral matter soluble ash, silica, fat (and its separate examination), crude fibre, cold-water extract, total nitrogen, foreign starch (if seen under the microscope), and added sugar. The average constituents of cocoa nib and shell were found to be:—

	Nib.	Shell.
Moisture	Per cent. 3.00	Per cent. 4.50
Total mineral matter	3.07	7.30
Silica	0.05	1.11
Fat	50.00	4.40
Crude fibre	2.80	14.00
Total nitrogen	2.50	2.50
Cold-water extract	11.60	22.00

THE quantity of added sugar in a sample of chocolate may be determined polarimetrically in a 20 per cent. solution of the sample, after clarification with lead acetate. As no satisfactory deductions can be made as to the quantity of actual cocoa in a chocolate from the proportions of any single constituent, the best results will be got by taking into consideration as many data as possible. Of these, the nitrogen, crude fibre, ash, and fat are the most important. The analytical results obtained on the examination of various samples of chocolate, adulterated chocolate, cocoa, and milk chocolate are given. In the case of milk chocolate the presence of the milk complicates matters by increasing the nitrogen and introducing a fresh variety of sugar and also of fat. As lactose is the only reducing sugar likely to be added to chocolate, the presence of milk can at once be inferred from the reducing power of the cold-water extract. Allowance must be made for the reducing power of the cold-water extract of genuine cocoa (which, expressed in terms of cupric oxide, is about 5 per 100 parts by weight of dry and fat-free cocoa), after which, the residual figure for copper oxide, multiplied by 1.13, will give a fair approximation to the non-fatty solids of the milk, and from this again the protein of the milk may be calculated. Or, the nitrogen belonging to the milk may be directly calculated from the corrected reducing power by multiplying the weight of copper oxide by the factor 0.0672. The nitrogen due to the true cocoa present can then be deduced, and the quantity of cocoa calculated. The quantity of milk fat will vary according to whether whole or partially

skimmed milk has been used. The following results were obtained on the analysis of various samples of milk chocolate:—

cloth laid in a box and obtained as a colourless tender jelly-like mass. This is cut into smaller rectangular pieces called "chô." Tofu has been stated to be a

	English (10 samples).			Swiss, German, Austrian, and Belgian (10 samples).		
	Lowest.	Highest.	Average.	Lowest.	Highest.	Average.
	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.
Total fat	23.7	36.0	31.8	29.2	33.4	30.8
Made up of—						
Milk fat	2.6	8.3	5.5	5.8	13.6	8.1
Cocoa butter	21.0	31.6	26.3	15.6	23.8	22.7
Milk sugar	3.8	11.1	8.04	5.2	11.0	8.26
Cane or beet sugar	32.4	54.3	43.2	35.0	52.7	42.6
Nitrogen (three samples)	0.76	1.08	1.18	1.10	1.30	1.24

All the samples were free from cocoa shell and foreign starch. In the absence of cacao butter substitutes containing the glycerides of volatile fatty acids, the Reichert process will give the amount of milk fat with reasonable accuracy. The United States Department of Agriculture defines chocolate as "the solid or plastic mass obtained by grinding cocoa nibs without the removal of fat or other constituents except the germ, and contains not more than 3 per cent. of ash insoluble in water, 3.5 per cent. of crude fibre, 9 per cent. of starch, and not less than 45 per cent. of cocoa fat." *Sweet Chocolate* is defined as "chocolate mixed with sugar (sucrose), with or without the addition of cocoa-butter, spices, or other flavouring materials, and contains in the sugar- and fat-free residue no higher percentage of either ash, fibre, or starch than is found in the sugar- and fat-free residue of chocolate." Board of Public Health of Victoria—*Definition*.—"Chocolate or sweet cocoa mass or confectioner's chocolate or chocolate coating is cocoa mixed with sugar, with or without the addition or subtraction of cocoa fat, and with or without the addition of spices or other flavouring substances." *Standard*.—"It shall contain in the sugar- and fat-free residue no higher proportion of starch, fibre, or ash than is found in the fat-free residue of standard cocoa mass, which itself is defined as containing not more than 3 per cent. of ash insoluble in water, 4.5 per cent. of total ash, 3.4 per cent. of crude fibre, 12 per cent. of starch (cocoa-starch), and not less than 45 per cent. of cocoa fat." Union of German Chocolate Manufacturers—*Definition*.—"A mixture of roasted and shelled cacao with sugar (beetroot-sugar), and an addition eventually of cacao-butter, vanilla, cinnamon, cloves, and other pieces or essential oils." Swiss Society of Analytical Chemists.—Definitions have been drawn up which will probably be rendered official. Chocolate is described as a mixture of cacao with sugar, either sold moulded or powdered." Amount of sugar varies from 40 to 70 per cent. No other ingredients admitted except spices vanilla, benzoin, Tolu or Peruvian balsams, cinnamon, cloves, nutmeg). Fat and sugar together should not exceed 80 to 85 per cent., and the remainder should consist of fat-free cocoa mass. Ash not to be above .5 per cent. Belgium and Roumania are the only two states with official regulations as to composition. Belgium insists on the presence of at least 35 per cent. of shelled cocoa, otherwise the word "chocolate" must be excluded. Roumania requires that chocolate must be made from cocoa beans and sugar only. The Austrian Codex describes chocolate as a uniform mixture of cocoa mass and white sugar in the proportion of 40 to 50 per cent. of the former and 50 to 60 per cent. of the latter, with a small amount of harmless aromatic substances.—W. P. S.

Tofu; *Physical-chemical studies on* —. Y. Kato. Mem. Coll. Sci., Kyoto Univ., 1908, 1, 325—331.

TOFU, a Japanese table preparation, is made from soya beans, which are soaked in water till they swell, then ground, and water added to give a milky solution. This is boiled and filtered hot to separate the skins, and the silky filtrate is coagulated with "bitter salt" solution, the residue obtained in making common salt by evaporation of sea water. The coagulum is filtered through a

chemical compound of protein with calcium and magnesium. After washing with water the amount of ash in the residue is very small and can be still further decreased by washing with dilute hydrochloric acid. The calcium and magnesium are probably present as phosphates. Tofu behaves as a negative colloid towards an electric current and is coagulated by electrolytes.—E. F. A.

Enkabang and teglam fats and katio oil. Brooks. See XII.

PATENTS.

Cattle food; Process of manufacturing —. T. E. Breyer, Waukegan, Ill. U.S. Pat. 920,108, May 4, 1909.

THE food is obtained from by-products resulting from the manufacture of starch from corn (maize). The steeping water, which remains after the corn has been soaked in a dilute solution of sulphurous acid, is treated with calcium hypochlorite, and sodium carbonate is then added. The precipitated phosphates and proteins are removed from the liquid, and the latter is evaporated to the consistency of a syrup. This syrup, together with the precipitated phosphates and proteins, is mixed with other feeding stuffs, and the mixture is dried.—W. P. S.

Butter; Process for renovating —. M. Montéran. Fr. Pat. 396,282, Jan. 21, 1908.

BUTTER fat (washed and purified as usual) and milk are conducted to an atomising apparatus, thence to a mixer, and the mixture is afterwards cooled and worked. These operations are carried out in an atmosphere of carbon dioxide.—W. P. S.

Margarine and the like; Process for the production of emulsions of —. J. V. M. Risberg. Fr. Pat. 396,456, Nov. 18, 1908. Under Int. Conv., Nov. 20, 1907.

THE mixture (oil, milk, etc.) from which the margarine is to be produced, is introduced into a centrifugal drum. As the latter rotates, the mixture is forced towards the walls of the drum, where it is collected in a tube and discharged through small openings against short baffle-plates fixed to the wall of the drum, the object being the production of a complete emulsion. The heat generated by the motion of the mixture in the drum, and which would retard or prevent the formation of the emulsion, is absorbed by a cold-water jacket surrounding the drum, by withdrawing a portion of the mixture and circulating it through a tube surrounded by a cold-water jacket, or by admitting air or other gas under a pressure of 100 atmospheres into the drum.—W. P. S.

Milk; Process for the control of — [detection of added water]. B. Santon. Fr. Pat. 396,679, Nov. 24, 1908.

THE process is based on the red coloration which is produced when milk is treated with sodium alizarinsulphonate, and the fact that a definite quantity of sulphuric acid must be added to genuine milk so treated in order to change the red coloration to yellow. Milk containing added water requires the addition of less sulphuric acid to effect the change in colour.—W. P. S.

Coffee; Process for the removal of caffeine from —.
L. Seisser. Fr. Pat. 396,930, Dec. 1, 1908. Under
Int. Conv., Dec. 5, 1907.

ABOUT 5 kilos. of unroasted coffee berries are placed in a closed centrifugal drum which is surrounded by a hot-water jacket. After the addition of about 15 kilos. of ethyl acetate, the drum is set in motion, so that the solvent and berries are mixed thoroughly, the temperature being maintained at 68° C. At the end of 3 hours, the solvent is drawn off and replaced by a further quantity of about 10 kilos. and the mixing and extraction are continued for a further two hours. The ethyl acetate is then run off, the berries are heated to 100° C. to remove the last traces of solvent, and finally dried at 40° to 46° C., the drum being rotated meanwhile. The ethyl acetate may be recovered by distillation and the caffeine separated from the residue.—W. P. S.

Coffee, cocoa, and similar substances; Process for roasting —.
T. Vogeler. Ger. Pat. 209,214, June 21, 1908.

In the roasting of coffee, cocoa, and similar substances, pure air or other inert gas is used as heating agent and is circulated over the materials in a closed system, heat being imparted to it only by means of suitable heated surfaces. In one form of apparatus described for carrying out the invention, a regenerative chamber is used which is supplied alternately with fuel gases from a furnace burning smokeless fuel, and with the air to be used as heating agent in the roasting process. Before the roasting process, the materials may be dried by passing a current of dry air through the apparatus and allowing it to escape into the atmosphere.—A. S.

Drying milk. J. R. Hatmaker, Paris. U.S. Pat. 920,952, May 11, 1909.

SEE FR. PAT. 366,751 OF 1906; THIS J., 1906, 1113.—T. F. B.

(B.)—SANITATION; WATER PURIFICATION.

Sewage effluents; The new standards for —. S. Rideal and W. T. Burgess. Analyst. 1909, 34, 193—205.

In the Fifth Report of the Royal Commission on Sewage Disposal (paragraph 322) provisional standards are suggested for the permissible amount of suspended matter in sewage, and for the maximum amount of atmospheric oxygen that the filtered liquid should absorb in definite periods. Adeney's apparatus for measuring the amount of oxygen absorption (this J., 1908, 837) has not proved satisfactory in the authors' hands, chiefly owing to the difficulty of preventing leakage of air during the shaking. They have therefore devised a colorimetric modification of Winkler's manganese method (this J., 1901, 841). The standards for the comparison are prepared by placing in each of 15 square-shouldered stoppered bottles (of 3 to 4 oz. capacity), 90 c.c. of water free from organic matter, 1.5 c.c. of 10 per cent. potassium iodide solution, and 0.15 c.c. of concentrated hydrochloric acid. The iodine tints corresponding to the various proportions of oxygen from 0.1 to 1.5 parts per 100,000 are then obtained by introducing into each bottle the calculated amount of a standard solution of potassium permanganate, after which the bottles are filled with distilled water (a minute bubble of air being left in each), closed, shaken, and kept in the dark. Under these conditions reliance may be placed upon them for more than a month. In testing a sample, the liquid is siphoned into one of the test bottles and treated with 0.5 c.c. of a nearly saturated solution of manganese chloride, followed by 1.5 c.c. of a solution containing 30 per cent. of sodium hydroxide and 10 per cent. of potassium iodide. The bottle is now closed and shaken, and, after the bulk of the precipitate has subsided, 1.5 c.c. of concentrated hydrochloric acid is introduced, and the bottle again shaken, and (preferably) cooled in water. The tint of the liberated iodine is then compared with the tints of the liquids in the standard bottles. If the water contains nitrites their amount should be determined (preferably by the metaphenylene-

diamine test), and a correction made for their oxygen equivalent. Two atoms of nitrous nitrogen correspond to one atom of oxygen. For the determination of dissolved oxygen in sewage effluents, about 1.25 litre of the sample is filtered and aerated by shaking, a note being made of the temperature and barometrical pressure. Three bottles, A, B, and C, of 250 c.c. capacity are completely filled with this liquid; and the stoppers tightly inserted. The remainder of the effluent is mixed with an equal quantity of distilled water, and shaken for two minutes, after which the temperature is noted, and two more bottles of the same capacity, D and E, completely filled with the mixture. To obtain concordant results it is essential that the bottles should be kept as nearly as possible at a constant temperature, say 15° C., during the 5 days over which the test extends. After 24 hours some of the effluent from bottle A is siphoned into a test bottle, the reagents are added, and the tint of the liberated iodine is compared with the standards as described above. In addition to the correction for nitrites it may be necessary to apply a correction for the colour of the effluent itself. For this purpose the tint of the untreated liquid may be compared with iodine standards corresponding to 0.02 and 0.04 part of oxygen. The undiluted effluent in the bottles B and C is examined at the end of 48 hours and 5 days respectively, and should these still contain a considerable proportion of oxygen, examination of the diluted effluent in bottles D and E will not be necessary. For transferring the liquids a siphon of glass tubing 5 to 6 mm. in diameter is used. This is cut above the longer limb, and the two pieces joined by rubber tubing, so that by pinching this with the fingers the flow of liquid may be stopped. With care the increase of oxygen during a single transference of water saturated to about one-fourth of its capacity need not exceed 0.01 part per 100,000. A single determination of nitrous nitrogen is, as a rule, sufficient, since the proportion of nitrite does not vary to any appreciable extent during the period of the tests—at all events in effluents in which the whole of the dissolved oxygen is not absorbed. —C. A. M.

XIX.—PAPER, PASTEBOARD, &c.

Cellulose [wood-pulp] factories; Recovery of by-products from soda —. H. Falk. Svensk Pappers Tidning; through Papierfabrikant, 1909, 7, 469—472.

THE author describes the plant employed in the researches of Bergström and Fagerlind (this J., 1908, 1037) for the condensation of the volatile by-products of the manufacture of wood-pulp by the sodium sulphide process. The vapours discharged from the digesters are first passed through a vessel in which particles of liquor are trapped, the steam is then conducted through a coil, and its heat utilised for warming fresh liquor. Condensation is completed in another coil immersed in a vessel of water and the condensed liquid is collected in the form of a milky, evil-smelling solution. Later, an oil separator at the top, and the water can be drawn off. Since the temperature of the condensate is still about 50° C., a further condenser is necessary, and the liquor collected from this likewise separates into an oily and aqueous portion; the oil consists of 30—50 per cent. of dimethyl sulphide, the rest being oil of turpentine. The gases uncondensable at the temperature of the cooling water contain methylmercaptan. This is absorbed in a vessel containing caustic soda lye, but the issuing gases still possess a bad odour. By passing them through a worm surrounded by ice and water, a further quantity of almost pure dimethyl sulphide, amounting to 500—700 c.c. per charge is condensed. Finally the gases are passed through water and burnt; these gases consist principally of atmospheric nitrogen, the oxygen having been absorbed in the digestion process; the combustible constituent is a sulphur compound. The composition of the condensed liquids collected in the various receivers varies with the temperature. Analyses of the total oily and aqueous

rtions showed the following yields per ton of cellulose
tained (from pine wood):

	In the oil.	In the water.
	Kilos.	Kilos.
mercaptan	0-062	0-06
methyl sulphide	0-927	0-17
methyl disulphide	0-103	0-05
t of turpentine	8-487	0-92
stillation residue	0-721	—
methyl alcohol	—	5-0
monia	—	0-18

he value of the oil is estimated at 5-18 kroner (5s.
4d.) and that of the aqueous portion at 2-60 kroner
s. 9-36d.). The dimethyl sulphide has a value as a
stitute for ether, as a solvent for nitrocellulose; this
ight be increased by converting it into the sulphoxide
the action of nitric acid. This solvent has the additional
vantage of being soluble in water and having a high
illing point. The mercaptan and the disulphide have
present no value. The value of the oil of turpentine
pends on the success of the process now being worked
t for refining it. It is proposed to use the residue
om the distillation of the oil of turpentine for the
anufacture of lampblack. The most important of the
ueous by-products is the methyl alcohol, which exists
the first condensation vessel at a concentration of about
per cent. and in the second of 6-7 per cent.—J. F. B.

ulose testing in the paper works. W. Vieweg. Verein

34, 1352-1353.

determine the degree of mercerisation (this J., 1908,
3) of cellulose, a quantity of the stuff is weighed into a
sk and shaken for half an hour with a measured quantity
N/2 caustic soda solution. A quantity of the resulting
la solution is then titrated with N/2 acid, using phenol-
thalein as indicator. The difference between the figures
tained before and after the immersion of the sample
es a measure of the degree of mercerisation of that
mple. A figure called by the author the "acid number"
obtained by weighing out a quantity of the cellulose
o a flask, adding a measured quantity of N/2 caustic
la solution and boiling for 1-hour, using a reflux
denser. Again the resulting soda solution is titrated
h N/2 acid. In this case the difference between the
tial and final strengths of the soda solution gives a
asure of the "acid number" of the sample of cellulose.
om a table of results it is seen that oxye-cellulose gives
higher figure than hydrocellulose. A further table
mpares the degree of mercerisation, the "acid number"
l the "copper number" of certain forms of cellulose.
e last-mentioned value has been investigated by
walbe and other chemists (see this J., 1908, 156).

Paper-making machines; Single-cylinder — S. Milne,
Edinburgh. Eng. Pat. 9002, April 25, 1908.

THE patentee claims, in single-cylinder paper-making
machines, the use in combination with a cylinder and
hood thereof, of a heater constructed separately from
the hood and arranged in such relation to it as to permit
of air being passed through it and through the space
between the hood and cylinder; a hood, whole or in
sections, and either corrugated or indented, or provided
with strips or otherwise adapted to baffle the air passing
between the hood and cylinder, and, when made in
sections, also adapted to facilitate access to the space
between the hood and cylinder.—T. H. P.

Papers; Method of manufacture in a paper machine of
coloured —, glazed on one face. L. E. Gossler. Fr.
Pat. 396,572, Nov. 21, 1908.

THE moist web of paper, immediately before reaching
the drying cylinder, is impregnated with the required
colour on the surface which will not be in contact with
the drying cylinder.—G. W. McD.

Cellulose material; Manufacture of a —. C. F. Cross
and J. F. Briggs, London. U.S. Pat. 920,828, May 4,
1909.

SEE Fr. Pat. 383,064 of 1907; this J., 1908, 330.—T. F. B.

Sizing paper; Manufacture of a material for —.
F. Curtius and Co. Fr. Pat. 396,985, Nov. 11, 1908.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

Aconitine from Japanese aconite tubers. K. Makoshi.
Z. allgem. österr. Apoth.-Ver., 1909, 47, 229-230.

Two varieties of Japanese aconite tubers were examined.
"Bushu" tubers ("Kusauzu" tubers from Hokkaido,
the true *Aconitum Fischeri*, Reich) yield an Alkaloid
termed jesaconitine. This substance does not crystallise.
On hydrolysis it yields benzoic acid, anisic acid, and
aconine. The formation of anisic acid distinguishes
jesaconitine from all other aconite bases. "Kusauzu"
tubers obtained from plants grown in Hondo belonging
to a variety of *Aconitum Fischeri*, yielded japaconitine.
The author finds the formula of japaconitine to be
C₃₄H₄₇NO₁₁, and that the triacetyl-derivative melts at
189° C. Japaconine yields a tetraacetyl-derivative melting
at 236°-237° C.—F. SHON.

Sapphire oil; Preparation and chief characters of —.
F. Borde. Bull. Sciences Pharmacol., 1909, 16,
132-142. Chem. Zentr., 1909, 1, 1566-1567.

THE specimens of oil examined by the author were
obtained by distilling with steam, sapphire plants
(*Crithmum maritimum*, L.) collected after flowering was
nearly finished. The plants contained 80-81.5 per cent.
of water. Of those collected in the first half of August,
the leaves and stalks yielded 3 grms. and the fruits 7 grms.
of oil per kilo.; in the second half of August the corres-
ponding figures were 1.5 grms. and 8 grms.; and in the
middle of September, 1.54 grms. and 7 grms. The dark
yellow oil obtained from the leaves and stalks is heavier
than water; the oil from the fruits is lighter in colour,

has a more pleasant odour, and is lighter than water. The characters of the oil from the ripe or dried fruits are given as follows:—It is a neutral, mobile, amber-coloured liquid distilling between 170° and 300° C.; sp. gr. at 0/4°, 0.95–0.98 (sp. gr. at 0/4° = sp. gr. at 0/4°–0.00084, t); n_D^{20} = 1.457–1.458; iodine value, 174–200; saponification value, 4–10; acetyl value, 3–4 (or possibly 0); solubility in 90 per cent. alcohol, 1:6; in 70 per cent. alcohol, 1:30.—A. S.

Irritant woods; An examination of —. Part I. Chloroxylonine from East Indian satinwood. S. J. M. Auld. Chem. Soc. Proc., 1909, 25, 148–149.

FROM East Indian satinwood, derived from *Chloroxylon swietenia*, which has been reported to possess irritant properties, have been separated calcium oxalate, a peculiar protein compound, two inert resins, a fixed oil, and an alkaloid, $C_{22}H_{23}O_7N$. As the alkaloid cannot be identified with any known base, it is proposed to call it *chloroxylonine*. Chloroxylonine is a weak monacidic base, and several of its salts have been prepared and characterised. It melts at 182–183° C., contains four methoxyl groups, and is levorotatory ($[\alpha]_D^{18}$ = –9°18'). In certain circumstances it seems capable of causing dermatitis similar to that ascribed to the wood itself.

Camphoric anhydride; New method of preparing —. J. P. Edgerton. Chem. Soc. Proc., 1909, 25, 149–150.

WHEN camphoric acid is treated with chlorosulphonic acid a vigorous reaction takes place according to the equation:

the principal product being camphoric anhydride, which can be quickly prepared as follows: One hundred grams of finely powdered camphoric acid are placed in a capacious flask fitted with a drying tube containing calcium chloride, and 33 c.c. of chlorosulphonic acid are added; the mixture is then warmed on the water-bath, a further quantity of 16.5 c.c. of chlorosulphonic acid is added, and the whole again warmed for about half an hour until the evolution of gas has practically ceased. The mass is then mixed with water, filtered through glass wool, and washed until free from acid. The camphoric anhydride crystallises from methylated spirit in fine needles, which, if not quite pure, can be obtained pure by a second crystallisation.

Terpinene; Action of chromyl chloride on —. Contributions to the chemistry of the terpenes. Part I. G. G. Henderson and W. Cameron. Chem. Soc. Proc., 1909, 25, 151.

WHEN chromyl chloride (2 mols.), largely diluted with carbon disulphide, is added to a similar solution of terpinene (1 mol.), a brown solid is formed which is decomposed by water, yielding a solution of chromic chloride and a brown, oily liquid. The liquid oxidation product contains small quantities of cymene and of a ketone of the formula, $C_{10}H_{16}O$, but is mainly composed of *a-p*-tolylpropaldehyde, $C_6H_4CH_2CH(CH_3)CHO$, and *p*-tolyl methyl ketone, $COCH_3C_6H_4CH_3$, both of which are derivatives of cymene. Hence the behaviour of terpinene towards chromyl chloride is different from that of pinene and of camphene, for whilst each of the latter hydrocarbons yields an additive product, $C_{10}H_{16} \cdot 2CrO_2Cl_2$, terpinene, on the other hand, is for the most part first oxidised to cymene, which then forms the compound $C_{10}H_{14} \cdot 2CrO_2Cl_2$, from which the aldehyde and the ketone are produced by the action of water.

Terpene series; A new method of isomerisation in the —. G. Austerweil. Compt. rend., 1909, 148, 1197–1199.

THE author points out that many of the reactions in the terpene group, which proceed in the vegetable kingdom, take place at a low temperature and under a considerable

pressure, namely, osmotic pressure. It is known that linalool is transformed into geraniol, *in vitro*, when heated with acetic acid in an autoclave to 160°–170° C., and it is pointed out that this reaction is simulated by plants, for essences obtained from plants in latitude 20° contain more geraniol relative to linalool than those occurring in a latitude of 44°–45°; under the influence of osmotic pressure, therefore, the denser substance tends to be formed. As an application of these ideas the author shows that whilst a yield of only 18 per cent. of borneol is obtained when pinene is heated in an autoclave with an organic acid, and resinification ensues if the temperature be raised to increase the pressure, if the pressure in the autoclave is artificially raised (by means of compressed carbon dioxide) and the operation carried out at about 200° C., a good yield of borneol can be obtained. It is necessary that the materials should be quite dry and the yields are still further improved if a small amount of the anhydride of the organic acid used is added.

—J. C. C.

Allyl and propenyl compounds in essential oils; Separation of — [by means of mercuric acetate]. L. Balbiano. Ber., 1909, 42, 1502–1506.

MIXTURES of compounds containing allyl and propenyl side chains, such as anethol and methylehaviol, can be separated by means of mercuric acetate (see this J., 1906, 442). The mixture is dissolved in ether, treated with a molecular proportion of mercuric acetate dissolved in water, and allowed to stand for 24 hours. The ethereal solution contains the unchanged propenyl derivative, whilst the acetomeric compound of the allyl derivative remains suspended in the aqueous portion. After extracting the aqueous solution with ether, the mercury compound can be decomposed by making the liquid alkaline with sodium hydroxide, and digesting with zinc. If steam is passed through, the allyl derivative is recovered. In this way the following mixtures were separated: anethol and methylehaviol, safrol and isosafrol, myristicin and isomyristicin, aniol and isosanol.

—F. SHDN.

Catalytic actions of colloidal metals of the platinum group. VI. Catalytic reductions with colloidal palladium. C. Paal and J. Gerum. Ber., 1909, 42, 1553–1560.

THE authors have continued their experiments upon the reduction of organic compounds by means of colloidal palladium (this J., 1907, 780; 1908, 864, 875). Benzoinitrile reduced by the method already described (*loc. cit.*) yields mono- and dibenzylamine, ammonia, and a little benzaldehyde. In the first stage of the reaction, 2 atoms of hydrogen appear to attach themselves to the $C \equiv N$ group to form benzylideneimine, which is transformed, in the presence of water, into benzaldehyde and ammonia. These two compounds then unite more or less completely to form hydrobenzamide, which, in turn, is reduced to mono- and dibenzylamine. Benzaldehyde-*cyanhydrin* yields on reduction, mono- and dibenzylamine, ammonia, and benzyl alcohol, instead of alcoholic bases as might be expected. The explanation suggested by the authors is that the oxynitrile in aqueous-alcoholic solution is more or less dissociated into benzaldehyde and hydrocyanic acid, and that the latter is reduced, with the formation of ammonia. The ammonia and benzaldehyde then unite to form hydrobenzamide, which, on hydrogenation yields the primary and secondary benzyl base; whilst the benzyl alcohol is derived from the benzaldehyde that has escaped condensation to hydrobenzamide. This reduction of hydrocyanic acid is the more striking, since experiments have shown that acid has a strong restrictive influence on the catalytic action of colloidal palladium. Benzaldoxime when hydrogenated at the ordinary temperature yields the same products of decomposition and reduction as benzonitrile, viz. benzaldehyde, ammonia, and mono- and dibenzylamine. The formation of these compounds may be explained on the assumption that the oxime is first reduced to benzalimine and that this is decomposed into benzaldehyde and ammonia.—C. A. M.

Hydroquinone [quinol]; Oxidation of — by the catalysis of carbon. M. Matsui. Mem. Coll. Sci., Kyoto Univ., 1908, 1, 386—390.

ANIMAL charcoal acts as a catalyst in bringing about the oxidation of quinol. Oxidation only takes place with access of air and proceeds more quickly at higher temperatures. It readily takes place in aqueous or alcoholic solution at ordinary temperature but in ethereal solution it is necessary to heat on the water-bath with a constant supply of air.—E. F. A.

Cinnamic acids; The isomeric —. H. E. Büllmann. Ber., 1909, 42, 1443—1450.

IN view of a recent paper by Liebermann on allo- and isocinnamic acids (this J., 1909, 441), the author has made further experiments. He has considered three acids, Liebermann's allocinnamic acid, m. pt. 68° C., Liebermann's isocinnamic acid, m. pt. 58° C., and Erlenmeyer sen.'s iso-acid, m. pt. 42° C. The author suggests that these should be described as allocinnamic acids. When a small quantity of the acid melting at 68° C. is melted and cooled in a freezing mixture, the acid melting at 42° C. is produced. If more than 0.1 gm. of the acid melting at 58° C. be melted and cooled, the melting point remains unchanged. When 1.0 gm. of the acid melting at 68° C. is melted and dissolved in 10 c.c. of light petroleum, the acid melting at 58° C. crystallises out, but if more of the solvent is used, the acid melting at 68° C. is deposited. Without exception, when a light petroleum solution of the acid melting at 68° C. is inoculated with the acid melting at 58° C., the latter acid crystallises out. The acid melting at 58° C. can be converted into the one melting at 68° C. by inoculating the light petroleum solution with the latter acid.—F. SHDN.

Solubility; Determination of — with the Pulfrich refractometer. Y. Osaka. Mem. Coll. Sci., Kyoto Univ., 1908, 1, 290—303.

THE Pulfrich refractometer may be used for determinations of solubility, including the solubility of organic compounds of volatile solvents, and gives reliable results. Accurate results can be obtained with small quantities of materials. The author's formula: $ax + bx^2 = \Delta$, where a and b are constants depending on the nature of the solvent and the solute, x is the amount in grms. dissolved in 100 c.c. of the solution, and Δ is the difference of the observed angles in the refractometer with the solvent and solution, is available within a wide range of concentration and is also applicable to cases in which a solution is used as a solvent or in which chemical reaction takes place between a solvent and a solute. The constants a and b are different at different temperatures. Tables are given showing results obtained with the refractometer.—E. F. A.

Ether; Solubility of — in water. Y. Osaka. Seventh Int. Congr. Appl. Chem., London, 1909.

THE solubility of ether in water determined by the method described in the preceding abstract, is as follows:—

Temperature:	0° C.	5°	10°	15°	20°	25°	30° C.
Solubility:	13.14	11.18	9.55	8.22	7.08	6.13	5.39

Light; Chemical action of —. G. Ciamician and P. Silber. Ber., 1909, 42, 1510—1515.

THE acid, $C_{10}H_{18}O_2$, corresponding to the aldehyde, $C_{10}H_{18}O$, obtained by the action of light on menthone is J., 1907, 777) was oxidised by means of permanganate in the presence of excess of sodium carbonate and at a temperature of 0° C. By this means β -methylglutaric acid and apparently isobutyric acid were produced, showing the acid, $C_{10}H_{18}O_2$, to have the constitution:

When menthone is exposed for a long time to the action of light in a moist atmosphere of oxygen, a keto-acid, $C_{10}H_{18}O_3$, is produced, which is identical with that obtained from the oxidation of menthol with chromic acid.—F. SHDN.

Thorium in monazite sand; Determination of —. V. Borelli. Gaz. chim. ital., 1909, 39, I., 425—448.

ABOUT 2 grms. of finely-powdered monazite are treated in a platinum crucible with 5 c.c. of sulphuric acid of sp. gr. 1.84 and a few c.c. of hydrofluoric acid, the crucible is fixed in a larger porcelain crucible by means of a ring of asbestos, and is heated gradually so that the hydrofluoric acid is evaporated in 1—2 hours and the sulphuric acid in 4—5 hours. When fumes are no longer evolved, the platinum crucible is allowed to cool, the greater part of the contents detached with a spatula and dissolved in about 10 c.c. of hydrochloric acid (1:1). After diluting with water to 50—60 c.c., the solution is decanted through a filter. The crucible is now half filled with concentrated hydrochloric acid (2:1), heated for a few minutes on the water-bath, the contents poured into a basin, the residue again digested with hydrochloric acid, and then the crucible carefully washed out, the whole of the contents being received in the basin. The contents of the latter are heated for $\frac{1}{4}$ hour on a boiling water-bath, diluted with water, the solution decanted through the same filter as used previously, the residue digested with concentrated hydrochloric acid, and the sequence of operations repeated three or four times until only a small quantity of a greyish-white, sandy residue, insoluble in dilute acid, is left. The solution (about 300 c.c.) is heated to boiling, treated with ammonia until the greater part of the acid is neutralised, i.e., until the precipitate formed re-dissolves only with difficulty, and then to the boiling solution, crystallised ammonium oxalate is added in small quantities at a time, until the precipitation of the rare earth oxalates is complete. After a few hours, the solution is decanted through a filter, and the precipitate washed by decantation and on the filter with a dilute solution of ammonium nitrate. The precipitate is taken up with 15—20 c.c. of nitric acid (1:1), heated to boiling, and potassium permanganate solution added till a pink colour persists. The solution is boiled to destroy the excess of permanganate, ammonia added until the solution is neutral or just faintly acid to litmus, and then 10 c.c. of a 3 per cent. solution of pure hydrogen peroxide added, and the whole heated for a few minutes at 60—80° C. The precipitate of thorium peroxide, coloured a more or less intense orange by cerium peroxide, is filtered off, and washed with a dilute solution of ammonium nitrate. The thorium peroxide is freed from the 5—8 per cent. of impurities it contains by re-dissolving in nitric acid and re-precipitating with hydrogen peroxide. It is then again washed with ammonium nitrate solution, ignited in a platinum crucible, and weighed.—A. S.

Cerium salts; Preparation of pure —, and the colour of cerium oxide. A. C. Neish. J. Amer. Chem. Soc., 1909, 31, 517—523.

THE following process of obtaining pure cerium salts obviates the necessity of tedious crystallisations. (1). *Hydrochloric acid treatment for removal of iron, calcium, etc.*—The crude cerium oxalate (150 grms.) is distributed in three beakers, heated for an hour on the water-bath with 750 c.c. of 1 per cent. hydrochloric acid, and the residues washed with the same acid and with hot water; then treated successively with 350 c.c. of 0.5 per cent., and the same quantity of 0.2 per cent. hydrochloric acid, and washed until no iron can be detected by the colour test with ammonium thiocyanate and amyl alcohol. (2). *Ammonium oxalate treatment to remove thorium, zirconium, and yttrium*—The residual oxalate from the above treatment, was removed from the funnel, a third placed in each beaker, and a hot solution of ammonium oxalate, saturated in the cold, was added. The beakers were heated on the water bath with frequent stirring, for an hour, and allowed to settle. The oxalate settled rapidly, and changed from a fine powder to a distinct crystalline form; it was filtered through a Buchner funnel, washed with 500 c.c. of ammonium oxalate solution, and well with cold water. This treatment is repeated three times with constant stirring and precautions to prevent the formation of lumps. (3). *Potassium hydroxide treatment to remove aluminium, etc.*—The residue from (2) is made into a cream with water and distributed among the three beakers, into

each of which is then introduced 75 grms. of potassium hydroxide and sufficient water to make up 500 c.c. The beakers are then heated, with constant stirring, until their contents boil, and after continuing the heating for 30 minutes, water is added, and the deposits collected in a Buchner's funnel, and washed with about 3 litres of hot water. (4). *Sulphuric acid and potassium sulphate treatment to remove yttrium, erbium, ytterbium, and samarium*.—About a third of the cerium ytterbium, left from the preceding treatment is placed in each beaker, together with 300 c.c. of water and about 30 c.c. of 50 per cent. sulphuric acid, which is added at intervals, and the whole heated to the boiling point. A little more acid is then added, and 10 to 20 c.c. of hydrogen peroxide solution, and the boiling continued until all the peroxide is decomposed. The contents of each beaker are now diluted to about 500 c.c., and cooled to about 10° C. (cerous sulphate being more soluble in cold than in strong acid), the supernatant liquid decanted, and the residue treated in the same way as before, until everything is dissolved. The solution (about 3 litres) is mixed with 100 grms. of potassium sulphate dissolved in 500 c.c. of boiling water, and allowed to stand overnight, after which the supernatant liquid is decanted, and the crystals of the double sulphate washed with warm water to remove the excess of the potassium salt. (5). *Treatment with potassium hydroxide and chlorine to remove lanthanum and didymium*.—The crystals of the double sulphate are mixed with sufficient water to fill about two-thirds of the beakers and with 20 c.c. of strong hydrochloric acid, and digested for 30 minutes on the water-bath. The liquid is then decanted and the treatment with acid repeated until solution is complete. An excess of solid potassium hydroxide is now added to the united liquids, which are heated until the whole of the cerium has been precipitated as hydroxide. The precipitate is collected in a Buchner's funnel and thoroughly washed with hot water, after which it is mixed with about 2100 c.c. of water and 200 grms. of potassium hydroxide in a large cylinder, and mechanically stirred, whilst a very slow current of chlorine is introduced until saturation is complete (20 hours). Further purification from didymium is effected by again converting the cerium oxide into cerous chloride and then into hydroxide by treatment with potassium hydroxide, treating the moist precipitate with 1000 grms. of potassium hydroxide and about 1½ litres of water, and saturating the liquid with chlorine as before. After removal of the supernatant liquid, a litre of potassium hypochlorite solution prepared from a 20 per cent. solution of potassium hydroxide is added, and the stirring continued for 5 hours. The residue from this treatment is mixed with water and 25 grms. of potassium hydroxide, and once more saturated with chlorine. The whole treatment of conversion into chloride and hydroxide and saturation with chlorine is then repeated, and the final deposit thoroughly washed to remove potassium salts. (6). *Hydrochloric acid and oxalic acid treatment to remove iron, etc.*—The residue from (5) is boiled with about 1500 c.c. of water and 150 c.c. of strong hydrochloric acid, final solution being effected by the addition of hydrogen peroxide. The resulting cerous chloride solution is mixed with 500 c.c. of strong hydrochloric acid, heated nearly to boiling point, mixed with a litre of oxalic acid solution (saturated in the cold), and allowed to cool. The first crop of crystals is collected in a Buchner's funnel, and washed with hot water and dried between filter-paper. The mother liquor is mixed with another 1000 c.c. of the oxalic acid solution and again allowed to crystallise. The oxides left on ignition of both crops of crystals should have a slight yellow tint, and be practically pure. A pink or reddish colour points to the presence of oxides of iron, etc., whilst if the oxide is very pale or nearly white, the presence of white oxides as impurities is indicated. The pale "chamois colour" of ceric oxide is not altered by ignition in oxygen, and is therefore not due to the presence of atmospheric nitrogen. Specimens of cerium oxalate thus prepared by the author contained only traces of lanthanum and insignificant traces of yttrium. Such traces may be eliminated by further treatment with chlorine in (5), and by an additional operation in (4) of adding potassium sulphate to a cold solution of the salt in sulphuric acid, and not heating the

liquid after the addition. The double sulphate is dissolved in potassium hydroxide solution, and once more precipitated.—C. A. M.

Cerium; Rapid volumetric method for the determination of — in the presence of other rare earths. F. J. Metzger, J. Amer. Chem. Soc., 1909, 31, 523–525.

The method is based upon the fact that cerous sulphate dissolved in sulphuric acid is quantitatively oxidised by means of sodium bismuthate into ceric sulphate. The excess of the reagent is removed by filtration, the ceric compound reduced by means of ferrous sulphate, and the excess of the latter titrated with potassium permanganate. Fifty c.c. of a solution of, e.g., cerium nitrate, containing about 0.2 gm. of cerium oxide are mixed with 20 c.c. of strong sulphuric acid and evaporated until fumes of sulphur trioxide appear. (If the earths are present as sulphates this evaporation is unnecessary.) The cold solution is mixed with 2 grms. of ammonium sulphate and about 80 c.c. of water, and then heated to boiling point with about 1 gm. of sodium bismuthate. After cooling somewhat, it is mixed with 50 c.c. of 2 per cent. sulphuric acid and filtered through a Gooch's crucible, and the residue washed with 100–150 c.c. of the same dilute acid. Ferrous sulphate solution is added to the filtrate until the yellow colour disappears, and the excess of iron salt is titrated back with standard permanganate solution. The value of the latter in terms of iron, multiplied by the factor 3.08415, gives the corresponding amount of cerium oxide (Ce_2O_3). The test experiments described show that the method gives accurate results, even in the presence of salts containing thorium, lanthanum, neodymium, praseodymium, yttrium, erbium, zirconium, samarium, and titanium. The yellow coloration produced in the oxidation of cerium by means of sodium bismuthate may be used as a delicate test for that metal. A distinct coloration is given by a solution containing 0.2 mgrm. of cerium oxide in 100 c.c. The intensity of the colour increases with the rise in temperature. It is suggested that this may be made the basis of a colorimetric method of determining small amounts of cerium in incandescent mantles, etc.—C. A. M.

PATENTS.

Dibromo-behenic acid; Strontium salt of —. E. Fischer, Berlin, Assignor to Farbenfabriken vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pat. 920,305, May 4, 1909.

The salt is obtained by treating an alkaline solution of dibromo-behenic acid with strontium chloride; it has the formula, $\text{Sr}(\text{C}_{22}\text{H}_{41}\text{O}_2\text{Br}_2)_2$. It is a white, tasteless, odourless substance and is almost insoluble in water and alcohol, but soluble in ether and chloroform. It is stated to be a valuable substitute for potassium bromide.

—W. P. S.

Silver compounds, soluble in water; Process for the preparation of stable organic —. A. Busch. Ger. Pat. 209,345, March 3, 1908. Addition to Ger. Pat. 193,740, Dec. 13, 1906.

By using the double salt of hexamethylenetetramine and silver carbonate, $5\text{C}_6\text{H}_{12}\text{N}_4 \cdot 3\text{Ag}_2\text{CO}_3 \cdot 15\text{H}_2\text{O}$, in place of the double salts of silver nitrate and hexamethylene-tetramine mentioned in the main patent (this J., 1908, 645), compounds more easily soluble in water than those previously described are obtained.—A. S.

Radium compound and process of making same. J. Reitz, Schmargendorf, Assignor to P. Simon, Plauen, Germany. U.S. Pat. 920,881, May 4, 1909.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Developers: Comparative study of the reducing power of organic — and of the methods of increasing or diminishing the contrasts of the image developed by each of them. A. and L. Lumière and A. Seyewetz. Seventh Internat. Cong. Appl. Chem., London, 1909.

ALL organic developers (except those which contain solvents for silver bromide) have the same reducing power, i.e., they will develop to the same extent feeble images of under-exposed plates, etc.

The contrasts in negatives can be decreased (1) by diluting the developer (save in the case of "hydramine"); (2) by increasing the proportion of sulphite (only applicable in developers which do not contain alkali, e.g., diamino-phenol); (3) by increasing the alkalinity of the developer especially suitable for pyrogallol, metol, and quinol); (4) by raising the temperature of the solution (principally used for adurol and quinol). On the other hand, contrasts may be increased (1) by reducing the quantity of alkali, e.g., in the case of developers without alkali, reducing the quantity of sulphite; (2) by lowering the temperature of the solution; (3) by addition of an alkali bromide. This last means is applicable to all developers, and gives the greatest increase of contrast with pyrogallol, quinol, durol, glycin, and eikonogen. (See also this J., 1909, 69.)—T. F. B.

PATENT.

Multi-coloured surfaces; Process for making —. Verein. Kunstseidefabr. A.G., Kelsbach on Maine, Germany. Eng. Pat. 21,840, Oct. 15, 1908. Under Int. Conv., July 23, 1908.

EE Fr. Pat. 395,165 of 1908; this J., 1909, 329.—T. F. B.

XXII.—EXPLOSIVES, MATCHES, &c.

Explosives; Importation of — into India. Board of Trade J., May 20, 1909. [T.R.]

A NOTIFICATION (No. 2721-13) of 14th April, 1909, providing for the amendment of the rules previously in force respecting importation of explosives into India (see this J., 1907, 840). These amended rules provide, *inter alia*, that certain explosives which have undergone the test prescribed by the rules made by the Governor of the Straits Settlements in Council under the Explosives Ordinance of 1899 may be imported by sea from Penang to the port of Victoria Point under license without testing, but subject, in some cases, to the production of a certificate as provided by the rule in force in the Straits Settlements.

It is also provided that certain explosives which have already undergone the prescribed test at the port of Rangoon may also be re-imported into the ports of Kyau, Sandoway, Kyaukpyn, Tavoy, Mergui, or Victoria Point under license without retesting, under certain conditions.

A Notification, dated 23rd April, 1909, states that, in accordance with the provisions of Sec. 17 of the Indian Explosives Act of 1884, picric acid, when kept, conveyed, exported, or sold in Berar shall, for whatever purpose used or manufactured, be deemed to be an "explosive," except in certain specified cases, within the meaning of the above-mentioned Act.

Consumption of sodium nitrate in U.S.A. Munroe. See VII.

PATENT.

Explosive material. H. Klaffke. Fr. Pat. 396,496, Oct. 16, 1908.

THE explosive, which is said to be particularly suitable for blasting rock, consists of potassium nitrate (73.9), sulphur (13.4), and cellulose (12.7 parts).—G. W. McD.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS.

Extraction apparatus for plant products, etc. S. J. M. Auld and S. S. Pickles. Chem. News, 1909, 99, 242.

THE apparatus here illustrated enables large quantities of material to be extracted by a boiling solvent, and also enables the latter to be recovered continuously without the need of separate distillation vessels. It consists of a large flask, A, closed by a stopper with two holes. Through one of these is passed a narrow tube ending in a thistle-funnel packed with cotton wool tied over with muslin or calico. The other part of this tube is bent so as to form a siphon opening into the second flask, B. The other tube passing through the cork of the extraction flask is connected with a condenser, and has a side tube which also communicates with the lower flask. The material is boiled with the solvent in A, until the latter is saturated. The stop cock, C, is then momentarily closed, and the liquid passes through the filter-tube into B. The solvent is then distilled from the flask B, and re-enters the extraction flask through the side tube.—C. A. M.

PATENTS.

Explosive and calorific values; Apparatus for measuring and indicating the — of gaseous mixtures. A. G. Evans, Rugby. Eng. Pat. 9150, April 28, 1908.

THIS apparatus consists, firstly, of a catalytic tube containing long-fibred asbestos or fine platinum (or osmium, palladium, etc.) wires on which finely-divided platinum or platinum black is deposited. The catalytic tube is connected so that a sample of the gaseous mixture to be measured passes through it, and is attached to a specially constructed, tubular, differential thermometer, an indicating mechanism, and a reducing valve. The indicating mechanism and a contact-piece move with the differential thermometer and break circuit with a fixed contact. The gaseous mixture is passed through one tube of the differential thermometer, then through the junction of the thermometer which is free to move, and, after having been heated or cooled by the catalytic action of the platinum, is passed through the second tube of the differential thermometer; the expansion of this second tube and consequent movement of the free end of the differential thermometer may be measured and indicated in any suitable way.—T. H. P.

INORGANIC—QUANTITATIVE.

Carbonates in presence of nitrites, sulphides or sulphates by means of potassium bichromate; Determination of —. E. R. Marle. Chem. Soc. Proc., 1909, 25, 154.

IT was proved that soluble carbonates and carbonates of bases which form soluble chromates are quantitatively decomposed by aqueous potassium bichromate. The action of potassium bichromate on nitrites has been investigated. On distillation with bichromate, a nitrite yields nitrous acid, although the mixed solution apparently contains no free nitrous acid. The yield of nitrous acid increases with the concentration of the nitrite, but is almost independent of that of the bichromate. Prolonged distillation, either adding water at the rate at which the

liquid distils, or making the solution up to its original volume after, say, 100 c.c. has distilled over, gives 60—70 per cent. of the nitrite as nitrous acid. The residual nitrite in the flask is estimated, and the loss of 10—15 per cent. is accounted for by the decomposition of nitrous acid into nitric acid and nitric oxide, some of the nitric oxide remaining dissolved in the bichromate solution. An apparatus was described with which carbonates can be estimated in the presence of nitrites, the mixture being distilled with bichromate under a reflux condenser. The carbon dioxide is thus freed from nitrous acid, and the nitric oxide formed is negligible. The method is found to give accurate results.

Thallium: Volumetric and gravimetric determination of — in alkaline solution by means of potassium ferri-cyanide. P. E. Browning and H. E. Palmer. Amer. J. Science, 1909, 27, 379—380.

The authors used a 1 per cent. solution of pure thallous nitrate, measured portions of which were taken, diluted to about 100 c.c. and an excess of potassium ferri-cyanide with potassium hydroxide added to precipitate all the thallium as the brown thallic hydroxide. The precipitate was filtered off on asbestos, generally without settling, and washed well with hot water. The filtrate was acidified with sulphuric acid, and the reduced ferrocyanide re-oxidised with standard potassium permanganate: $\text{Ti}_2\text{O}_3 + 4\text{K}_3\text{Fe}(\text{CN})_6 + 4\text{KOH} \rightarrow \text{Ti}_2\text{O}_5 + 4\text{K}_4\text{Fe}(\text{CN})_6 + 2\text{H}_2\text{O}$; $5\text{K}_4\text{Fe}(\text{CN})_6 + \text{KMnO}_4 + 4\text{H}_2\text{SO}_4 \rightarrow 5\text{K}_3\text{Fe}(\text{CN})_6 + 3\text{K}_2\text{SO}_4 + \text{MnSO}_4 + 4\text{H}_2\text{O}$. For the gravimetric determination, the precipitated thallic hydroxide was filtered on to asbestos felt in a perforated platinum crucible, dried at about 200° C. till of constant weight, and weighed as thallium sesquioxide. Tables showing the results of twelve determinations by each method are given.—F. R.

New Books.

THE RISE AND PROGRESS OF THE BRITISH EXPLOSIVES INDUSTRY. Published under the auspices of the VIIth International Congress of Applied Chemistry by its Explosives Section—Vice-President (Explosives Section), T. G. TULLOCH; and a Publication Sub-Committee, Major COOPER-KEY, OSCAR GUTTMANN, and W. R. HODGKINSON, with E. A. BRAYLEY HODGETTS as Editor. Whittaker and Co., 2, White Hart Street, Paternoster Square, London, E.C. 1909. Price 15s. net. 64 and 66, Fifth Avenue, New York. 1909.

SMALL quarto volume, containing 418 pages of subject matter, with frontispiece, and 39 illustrations. The subject matter is subdivided as follows:—PREFACE (T. G. Tulloch). HISTORICAL. I. History of gunpowder (E. A. B. Hodgkiss). II. Researches on gunpowder (G. W. MacDonald). III. Nitrocellulose (G. W. MacDonald). IV. Nitroglycerine and its explosives (H. de Mosenthal). V. Researches on nitroglycerine (G. W. MacDonald). VI. Permitted explosives (H. de Mosenthal). VII. Percussion caps (E. W. Hulme). VIII. Bickford's safety-fuse (Sir G. J. Smith). IX. Military fireworks (J. R. J. Jocelyn). X. Pleasure fireworks (Ph. Pain). XI. Legislation (E. A. B. Hodgkiss). XII. Bibliography. XIII. Chronology (1242—1700). XIV. List of gunpowder makers up to 1800. DESCRIPTIVE. EXISTING GOVERNMENT ESTABLISHMENTS. I. The Royal Laboratory, Woolwich (Col. Sir H. W. W. Barlow). II. The Royal Gunpowder Factory, Waltham Abbey (Col. Sir F. L. Nathan). III. The Research Department (Major J. H. Mansell). PRIVATE ESTABLISHMENTS. MANUFACTURERS OF PICRIC ACID.

DAS ARBEITEN MIT FARBENEMPFINDLICHEN PLATTEN. Von Dr. E. KÖNIG. Gustav Schmidt's Verlag, Berlin, W. 10. 1909. Price M.2 25.

SMALL 8vo volume, containing 75 pages of subject matter, 30 illustrations, and an alphabetical index. The subject matter is sub-divided as follows:—I. Introduction. II. Sensitizers. III. Preparation of plates sensitive to colours. IV. The light filter. V. Testing plates sensitive to colour. VI. Preparation and use of plates sensitive to colours: (a), Development. (b), Dark-chamber illumination. (c), Photography of portraits. (d), Landscape photography. (e), Photography of plants, &c. (f), Reproductions. VII. Orthochromatic photography by artificial light. VIII. Orthochromatic photography with silver-bromide collodion.

GRUNDRISS DER KOLLOIDCHEMIE. Von Dr. W. O. OSTWALD. Privatdozent an der Universität Leipzig. Theodor Steinkopff's Verlag, Dresden. 1909. Price M.12. Strongly bound, M.13.50.

Svo volume, containing 509 pages of subject matter, with portrait of Thos. Graham as frontispiece, also alphabetical indexes of names of authors and subjects. The subject matter is classified and subdivided according to the following scheme:—I. History of colloidal chemistry, from Graham to Barus and Schneider (1851—1891); and from Barus and Schneider, to the discovery of ultramicroscopy (1891—1903). The newer phases of colloid chemistry (1903 to the present). II. General chemistry of colloids. Theory. III. Special chemistry of colloids. a.) General physico-chemical properties of colloids. b.) Alteration of condition of colloids. Stability of colloid systems.

COLLOIDS AND THE ULTRAMICROSCOPE. A MANUAL OF COLLOID CHEMISTRY AND ULTRAMICROSCOPY. By Dr. RICHARD ZSIGMONDY. Authorised translation by JEROME ALEXANDER, M.Sc. First Edition. John Wiley and Sons, New York. Chapman and Hall, Limited, London. 1909. Price \$3.00, or 12s. 6d. net.

His work, Svo size, contains 238 pages of subject matter, and two coloured plates in addition, with one page of explanations. There are 11 illustrations, and an alphabetical index of subjects. The extent of the subject may be gathered from the classification of the text. Limitation of the field. II. Classification of hydrosols according to two different points of view. III. History of the irreversible colloids. IV. Facts pointing to the homogeneity of gold hydrosols. Development of ultramicroscopy. V. Description of apparatus for making visible ultramicroscopic particles. Principles of the ultramicroscopical investigation of gold solutions, fluids, certain solutions and suspensions, &c. VI. Preparation of colloidal gold solutions. VII. Motion of the gold particles. VIII. Size and colour of the particles, &c. IX. Colour change of colloidal gold; also its precipitation and protection. X. Filtration experiments. I. Amicroscopic nuclei in colourless ruby glass. II. General remarks concerning metal hydrosols; also concerning the formation of hydrosol and hydrogel.

THE MANUFACTURE OF RUBBER GOODS. A PRACTICAL HANDBOOK FOR THE USE OF MANUFACTURERS, CHEMISTS, AND OTHERS. By ADOLF HEIL and Dr. W. ESCH. English Edition by EDW. W. LEWIS. Chas. Griffin and Co., Ltd., Exeter Street, Strand, London. 1909. Price 10s. 6d. net.

Svo volume, containing 231 pages of subject matter, with 100 illustrations, and alphabetical indexes of subjects and names. The subject matter is classified by subdivision into the following groups:—I. Plan and arrangement of a rubber-goods factory. II. The raw material. III. The vulcanisation of rubber. IV. The mixings. V. The manufacture of soft-rubber articles. VI. Manufacture of ebonite. APPENDIX I. The regeneration or reclaiming of rubber waste as carried off in rubber factories.

PRACTICAL TESTING OF GAS AND GAS METERS. By C. H. STONE, Chief Inspector of Gas, Public Service Commission, 2nd District, New York. First Edition. John Wiley and Sons, New York. 1909. Price 15s. net. Chapman and Hall, Ltd., London.

Svo volume, containing 300 pages of subject matter, with additional Appendix, containing tables of numbers, of pages, 324 pages in all (exclusive of the preface), and alphabetical index of subjects. There are 51 illustrations, and the work is divided into Parts I. to IV., which in the sub-sections may be defined as follows:—PART I.—PHOTOMETRY. (i.) The photometer, &c. (ii.) Standards and burners. (iii.) Candle-power tests of oil- and water-gas, using candles as standards. (iv.) Photometric work with other standards and gases. (v.) Interpretation of results, and legal requirements. PART II.—CHEMICAL TESTS. (i.) Carbonic acid and sulphuretted hydrogen. (ii.) Total sulphur. (iii.) Other impurities. (iv.) Analysis of gas. PART III.—CALORIMETRY, SPECIFIC

GRAVITY, AND PRESSURE. (i.) Junker and Boys' calorimeters. (ii.) Other instruments and methods. (iii.) Consideration of results. (iv.) Specific gravity and pressure. PART IV.—TESTING OF METERS. (i.) The cubic foot and meter prover. (ii.) Method of testing meters.

ANLEITUNG ZUR BIOLOGISCHEN UNTERSUCHUNG UND BEGUTACHTUNG VON BIERSWÜRZE, BIERHEFE, BIER U. BRAUWASSER ZUR BETRIEBSKONTROLLE, SOWIE ZUR HEFENREINZUCHT. Von Prof. Dr. H. WILL. R. Oldenbourg's Verlagsbuchhandlung, München und Berlin. 1909. Strongly bound, price M.12.00.

Svo volume, containing 439 pages of subject matter, with 84 illustrations, and 3 tables; also an appendix of 8 pages; 447 pages in all. An alphabetical index of subjects closes the work. The classification of the subject is as follows:—I. Aim and scope of biological research in connection with brewery management. II. Varieties and definitions of beer worts. III. Varieties and definitions of bottom fermentation yeasts. IV. Yeast cells. V. Various groups of yeasts, etc. VI. Morphological and physiological functions whereby to distinguish the groups of culture yeasts and wild yeasts, the varieties of true yeasts, and the remaining budding fungi. VII. Deposits from stored and ripe beers. VIII. The different kinds of turbidity in beers. IX. Course of investigation of beer yeasts, young beer, stability samples, sick beers, beers in cask, and works. X. Biological water analysis. XI. Testing for sarcina (pediococci) according to the Bettges and Heller process. XII. Control of operations. XIII. Pure yeasts culture, and its technology, etc. XIV. Management of the pure yeast department; also, its biological control.

MANUAL OF VOLUMETRIC ANALYSIS FOR THE USE OF PHARMACISTS, SANITARY AND FOOD CHEMISTS, AS WELL AS FOR STUDENTS IN THESE BRANCHES. By HENRY W. SCHIMPF, M.D. Fifth Edition, revised and enlarged. John Wiley and Sons, New York. 1909. Price \$5.00, or 21s. net. Chapman and Hall, Ltd., London.

LARGE Svo volume, containing 697 pages of subject matter, and 102 illustrations, followed by an alphabetical index. The text is subdivided according to the following scheme:—I. General principles. II. Volumetric solutions. III. Indicators. IV. Apparatus used; weights and measures, etc. V. Methods of calculation. VI. Some vicarious volumetric methods. VII. Neutralisation analysis. VIII. Analysis by precipitation; also by oxidation and reduction. IX. Acetic acid and acetates; boric acid and borates; carbonic acid and carbonates; halogens; citric acid and citrates; cyanogen and compounds; nitrogen and compounds; oxalic acid and oxalates; oxygen and peroxides; phosphoric acid and phosphates; salicylic acid and salicylates; sulphur and its compounds. X. Metals: aluminium to zinc. XI. Sanitary and volumetric analyses of organic medicinal substances. XII. Analyses of milk and butter; technical examination methods for fats, oils, and waxes. XIII. Soap. XIV. Starch determination in cereals. XV. Determination of sugars. XVI. Alkaloids. XVII. Vegetable drugs. XVIII. Galenical preparations. XIX. Phenol; glycerin; tannin; formaldehyde; chloroform and chloral hydrate. XX. Assay of surgical dressings. XXI. Determination of compound ethers. XXII. Urine. XXIII. Some gasometric methods. The nitrometer. XXIV. Determination of nitrites; hydrogen peroxide; soluble carbonates, etc. XXV. Determination of urea and uric acid.

Patent List.

I.—PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

11,988. Draper. Apparatus for separating substances of different specific gravities.* May 21.

12,004. Hansen and Winkler. Centrifugal apparatus for eliminating air or gas from liquid.* May 21.

- 12,154. Lofthouse. Apparatus for separating materials. May 24.
 12,463. Lennox. Revolving drying machines. May 26.
 12,465. Lennox. Machine for drying briquettes of peat or coal, salt, chemicals, etc. May 26.
 12,583. Bowing. Retorts and furnaces. May 27.
 12,661. Kruse, Dines, and Richardson. Filter presses. May 28.
 12,739. Calico Printers' Assoc., Browning, and Barlow. Apparatus for separating solid impurities from viscous or gummy solutions.* May 29.

COMPLETE SPECIFICATIONS ACCEPTED.

- 11,388 (1908). Eijndman. Apparatus for evaporating liquids. June 3.
 16,128 (1908). Steynis. Apparatus and process for simultaneously treating liquids and gases chemically active upon each other. June 3.
 1381 (1909). Hunt (Löve). Lixiviating apparatus, especially for extracting sodium nitrate from caliche. May 26.
 2101 (1909). Bramwell. Filtering apparatus. May 26.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

- 11,639. Oswald and Oswald. Suction or pressure gas plant.* May 17.
 11,675. Farnham. Gas producer. May 18.
 11,756. George. Gas producers.* May 18.
 11,800. Wilson. Apparatus for distilling coal. May 19.
 11,890. Crossley and Rigby. Gas producer plant for recovery of ammonia. [Comprised in No. 17,978, Aug. 27, 1908.] May 20.
 12,247. Scheidig. Production of power gas from bituminous fuel.* May 24.
 12,363. Koppers. Coking and gas-generating ovens.* May 25.
 12,465. Lennox. *See under I.*
 12,466 and 12,467. Haddan (Bruno-Patente-Verwerthungs). Manufacture of incandescence bodies.* May 26.
 12,474. Grote. Manufacture of filaments for incandescence electric lamps. May 26.
 12,534. Heinen. Gas generators.* May 27.
 12,569. Stearn and Topham. Manufacture of metallic filaments for incandescence electric lamps. May 27.
 12,652. Mehler and Lohmann. Measuring the calorific value of solid fuel. May 28.
 12,686. Bourdos. Manufacture of filaments for electric amps. May 28.
 12,742. Gearins, Fullwood, and Boucher. Manufacture of coke and gas, construction of gas retorts, and recovery of by-products. May 29.

COMPLETE SPECIFICATIONS ACCEPTED.

- 10,625 (1908). Boulton (Wulff et Cie.). Manufacture of briquettes of coal or ores. May 26.
 10,891 (1908). Wolfram Lampen A.-G. Manufacture of filaments for electric incandescent lamps. May 26.
 17,103 (1908). Bone and Wheeler. Gas producers. June 3.
 17,621 (1908). Coolidge. Manufacture of refractory electric conductors. May 26.
 27,144 (1908). Kroll and Saklatwalla. Production of pure and thin filaments for illuminating. May 26.
 28,349 (1908). Rindom. Gas retorts. June 3.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

APPLICATION.

- 12,001. Knottenbelt. Petroleum and other hydrocarbon oils. May 21.

COMPLETE SPECIFICATION ACCEPTED.

- 10,959 (1908). Seidenschmur. Distilling crude petroleum. May 26.

IV.—COLOURING MATTERS AND DYESTUFFS

APPLICATIONS.

- 11,590. Claus and Co., and Claus. Manufacture of black colouring matters containing sulphur. May 17.
 11,736. Ellis (Chem. Fabr. vorm. Sandoz). Manufacture of blue to violet dyestuffs of the gallocyanine series May 18.
 11,928. Newton (Bayer und Co.). Manufacture of blue dyestuffs of the anthracene series. May 20.
 11,929. Newton (Bayer und Co.). Manufacture of acid wool dyestuffs. [Addition to No. 7820 of 1909.]* May 20.
 11,930, 11,931, and 11,932. Newton (Bayer und Co.). Manufacture of anthracene derivatives. May 20.
 12,205. Newton (Bayer und Co.). Manufacture of azo dyestuffs. May 24.
 12,206. Newton (Bayer und Co.). Manufacture of β -methyltetramethylenediamine. May 24.
 12,207. Newton (Bayer und Co.). Manufacture of dyestuffs of the gallocyanine series. May 24.
 12,371. Meister, Lucius, and Brünig. Manufacture of disazo dyestuffs. [Ger. Appl. July 2, 1908.]* May 25.
 12,456. Bloxam (Act.-Ges. f. Anilinfabr.). Manufacture of monoazo dyestuffs for chrome-mordanted wool. [Addition to No. 6729 of 1909.] May 26.
 12,568. Johnson (Badische Anilin und Soda Fabrik). Manufacture of colouring matters of the anthracene series May 27.
 12,653. Ullmann. Manufacture of dyestuffs of the anthraquinone series. [Ger. Appl., March 2, 1909.] May 28.

COMPLETE SPECIFICATIONS ACCEPTED.

- 11,866 (1908). Newton (Bayer und Co.). Manufacture of azo dyestuffs. May 26.
 15,908 (1908). Vidal. Colouring matters for animal fibres. June 3.
 20,368 (1908). Newton (Bayer und Co.). Manufacture of dyestuffs of the gallocyanine series. June 3.
 20,709 (1908). Ransford (Cassella und Co.). Manufacture of dyestuffs. June 3.
 27,095 (1908). Knoll und Co. Phenol-phthalein compounds. May 26.
 2290 (1909). Act.-Ges. f. Anilinfabr. Manufacture of sulphurised dyestuffs soluble in water. May 26.
 7905 (1909). Act.-Ges. f. Anilinfabr. Manufacture of disazo dyestuff. June 3.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

APPLICATIONS.

- 11,729. Chem. Fabr. Griesheim-Elektron. Treatment of mercerised cotton goods. [Ger. Appl., Oct. 19, 1908.] May 18.
 11,881. Togo Spinning Co., and Atack. Apparatus for treating fibrous material with dye and other liquor May 20.
 12,772. Denton and Atkinson. Mercerising. May 29.

COMPLETE SPECIFICATIONS ACCEPTED.

- 7345 (1908). Calico Printers' Assoc., and Fourneau. Production of black on textile fibres. June 3.
 7671 (1908). Halliwell, and Mather and Platt, Ltd. Apparatus for dyeing, bleaching, and treating fibrous materials. May 26.
 16,330 (1908). Leachman. Treatment of wool, cotton, flax, and other fabrics. May 26.
 17,267 (1908). Ransford (Cassella und Co.). Treatment of dyeings with sulphide colours. May 26.
 20,200 (1908). Johnson (Kalle und Co.). Production of discharge effects on textile fibres or fabrics. May 26.
 21,280 (1908). Crefelder Seifenfabr. Stockhausen und Traiser. Emulsions for use in washing raw wool and for other purposes. June 3.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

- 11,694. Lawes and Co., and Davis. Manufacture of tartaric acid. May 18.
 11,890. Crossley and Rigby. *See under II.*
 12,106. Carrick and Pattison. Preparation of iron compounds.* May 22.
 12,226. Feld. Treatment of metallic cyanides to obtain hydrocyanic acid.* May 24.
 12,235. Macan. Production of zinc oxide from the residues of calcination of calamine tailings, etc. May 24.
 12,241. Elborne and Keeble. Manufacture of nitrogen compounds.* May 24.
 12,399. Bell. Production and application of oxides of chromium. May 26.
 12,480. Eckford. *See under XIII.1.*

COMPLETE SPECIFICATIONS ACCEPTED.

- 10,781 (1908). England. Treatment of sulphate of ammonia. May 26.
 20,171 (1908). Erste Oesterr. Soda-fabr., and Opl. Manufacture of sulphuric acid. May 26.
 24,264 (1908). Kettler. Production of compounds containing nitrogen and oxygen. June 3.
 26,581 (1908). Telchinnia. Manufacture of sodium cyanide. June 3.
 52 (1909). Firman and Cocksedge. Apparatus for making sulphuric and other similar acids. May 26.
 1381 (1909). Hunt (Love). *See under I.*

VIII.—GLASS, POTTERY, AND ENAMELS.

APPLICATIONS.

- 11,633. Heller and Baugartl. Manufacture of ceramic ware.* May 17.
 12,180. Dennis. Kiln for firing pottery, enamel ware, glass ware, enamelling, etc. May 24.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATION.

- 12,587. Hasselmann. Preservation of wood and composition therefor. [Ger. Appl. May 27, 1908.]* May 27.

COMPLETE SPECIFICATIONS ACCEPTED.

- 12,597 (1908). Cawley and Moore. Manufacture of a new building material. May 26.
 14,619 (1908). Brearley and Moorwood. Manufacture of silica, bricks, ganister, and other refractory materials. May 26.
 7197 (1909). Brearley and Moorwood. Manufacture of silica bricks and ganister. May 26.

X.—METALS AND METALLURGY.

APPLICATIONS.

- 11,702. Cowper-Coles. Case-hardening iron and steel. May 18.
 11,703. Cowper-Coles. Desulphurising and dephosphorising iron. May 18.
 11,863. Fennell and Sackett. Furnaces for treating metals and metalliferous ores.* May 19.
 11,914. Wallis. Metallurgy of tin. May 20.
 12,018. Queneau. Metallurgy of zinc. May 21.
 12,198. Huntington. Agglomerating and desulphurising ores and separating volatile from non-volatile or metalliferous substances.* May 24.
 12,266. Wynne. Treatment of ores, etc. May 25.
 12,337. Reid. Separating and refining metals. [U.S. appl., Sept. 23, 1908.]* May 25.
 12,565. Crispo. Extraction of copper from copper residues. [Addition to No. 6730 of 1907.]* May 27.

COMPLETE SPECIFICATIONS ACCEPTED.

- 8534 (1908). Bradley. Treating metals to prevent oxidation and corrosion. May 26.

- 10,625 (1908). Boulton (Wulff et Cie.). *See under II.*

PROCEEDINGS OF THE 28TH ANNUAL GENERAL MEETING.

ERRATA.

This Journal, June 15th, 1909, p. 553, col. 2.

Mr. R. FORBES CARPENTER, in moving the adoption of the Report of Council, is reported to have said that "it was a letter from Mr. Reid to Lord Rayleigh which induced the Royal Society to appoint two representatives from that Society on the Board." The actual text was as follows:—"It was due to the action of Mr. Reid in bringing before the Council the proposed draft constitution of the Governing Body of the Laboratory that the Council resolved that the then President, Mr. George Beilby, should bring before Lord Rayleigh the claims of the Society of Chemical Industry for representation. This was the origin of the now celebrated letter of Dr. then Mr. George Beilby, to Lord Rayleigh, which secured to the Society the representation desired." Mr. Carpenter also went on to say:—"He also desired to emphasise the importance to the Society of the proposal of the English Ceramic Society to obtain skilled assistance in considering systematically the questions arising in connection with refractory materials. The Institution of Gas Engineers was already considering this matter, stimulated by the important paper of Mr. Bywater read at its 1908 meeting, and was also preparing to co-operate with the English Ceramic Society. No more important conferences could be held, having regard to the magnitude of the gas and coke oven industries."

Page 580, col. 1, line 2, for "rendu" read "rendus."

kind of plant. Unfortunately these difference-meters, as they may be called, have one defect, namely, that small quantities of steam are not registered. To what incorrect statement this defect can lead may be shortly exemplified as follows:—

If a difference-meter be installed before two engines of 30 and 150 h.p. respectively, then with both engines running the meter gives exact information as to the quantity of steam consumed. But if the 150 h.p. engine be stopped, the difference-meter does not show any measurable deflection, in other words, the steam consumed by the 30 h.p. engine alone cannot be measured. Therefore, in cases where the steam consumption varies considerably, these difference-meters cannot be used if a high standard of exactness is required.

The Farbenfabriken vorm. Friedr. Bayer & Co. used a number of these difference-meters for a long time, until they succeeded in 1902 in devising an instrument considerably superior in every respect to the difference-meter above mentioned. This meter determines the sectional area of the current of steam; hence it applies a principle quite different from that of the differential-meter. The new steam-meter is based on the following simple formula which applies to gases and liquids:—

$$W = S \cdot \gamma \cdot V$$

In this formula, W is the total steam passing through the meter, expressed in kg. per. sec., S the sectional area in sq. meters, V the velocity of steam in meters per. sec., and γ the weight of 1 cbm. of steam of the average pressure expressed in kg.

London Section.

Meeting held at Burlington House on Monday, May 3rd, 1909.

DR. J. LEWKOWITSCH IN THE CHAIR.

A NEW STEAM-METER.

BY E. A. J. KUHNKE.

In most chemical factories, steam is one of the chief items in the cost sheet. In spite of this undeniable fact, hitherto there has been no suitable instrument for accurately determining the amount of steam consumed by each plant and apparatus, and for permanently controlling it, whereas for water, gas, electricity, and similar means for conveying power, available measuring instruments have existed for some time and are frequently used with advantage.

The first measuring instruments for steam were constructed after the type of the screw-propeller-meter, at the high speed at which the blades must run in view of the high velocity of the steam, and, especially, the difficulty of transmitting the motion of the propeller to a counter outside without causing too much friction, very soon led to the abandonment of this system. Other devices which became important in practice were based on the idea of producing artificial throttling of the current of steam and consequently a difference pressure. This difference was then measured and the quantity of steam passing through a conduit was calculated with the aid of Napier's formula,

$$W = v \cdot S \cdot \sqrt{\frac{p_0 - p}{\gamma_0}}$$

A number of apparatus based on such devices have been brought out and these instruments admittedly present an important advance in the measurement of steam, and they are in use with good effect in every

Under all conditions of gases passing through a pipe, S will, as a rule, remain invariable, while γ and V will

vary. However, it is possible, by making S variable, to make V , which can only be measured with difficulty, constant for each γ . This possibility, viz., of keeping V constant in a gas current by varying the sectional area has been effected in a simple manner. In a casing a hollow truncated cone is fixed and within it a disc which can move freely up and down is suspended by a wire. The wire is led through the bonnet of the casing over a pulley and balanced by a counter weight. The steam entering the box must pass through the truncated cone in order to flow to the place of consumption; consequently the disc is forced downwards and stops in a position the sectional area of which is determined by the actual consumption of steam. That is to say, the disc balanced by the weight keeps such a position that the difference of the pressure in front of it and behind it remains constant. If the quantity of steam passing through the box increases, owing to an increase in the consumption, the difference of pressure before and after passing the disc, and consequently the velocity of the steam, would increase if the disc were fixed and the sectional area of the passage constant. But the disc, being free to move downwards, responds to the increase of pressure and opens a larger annular section for the steam and so restores the original difference of pressure and velocity. Of course, the case will be the reverse if the consumption decreases; the disc will then rise in proportion to the diminishing difference of pressure and thus reduce the sectional area. In all cases the difference in pressure is dependent upon the weight hanging on the wire. This weight must be balanced by the pressure of the steam on the disc. The positions of the disc having been once adapted to the actual conditions, the quantities of steam passing through, are registered on a clock-work drum, mounted upon the bonnet without any intervening lever, so that it is possible to ascertain at any time the actual section available for the steam by measuring the distance of the indicator from the baseline, provided, of course, that the construction of the truncated cone is known. If the sectional area available over a long period has to be ascertained, it is necessary—in case the rate of consumption has varied—to ascertain the average distance of the line, traced by the pencil, from the baseline. This can be done most simply and exactly by means of a planimeter. Of course, to make this possible the annular sections passed by the steam must increase in linear proportion, so that the section of the side of what we have called the truncated cone cannot be a straight line—for then the increase of section would be in proportion to the square of the distance traversed by the disc. The section of the side of the "cone" must be a parabola. The disc moving within the hollow truncated cone has exactly the same diameter as the upper opening of the truncated cone, so that in its topmost position it closes tightly the opening. By this arrangement even the smallest quantity of steam passing through the apparatus must be indicated. This is an excellent feature of the sectional meter and herein lies its superiority over all other systems. The specific weight, that is the weight of steam per cbm. is, for saturated steam, proportional to the pressure. Therefore when the pressure is known, the specific weight is also known, and it is only necessary to register continuously the steam pressure. This is done on the same clock-drum, on which the scale distances are traced, at its lower end by means of a spring steam gauge in the usual way. Of the three factors necessary for determining the quantity of steam by means of the above given formula, the velocity is still wanting. This has been kept constant for each specific weight, as shown above, by enabling the sectional area to vary and to adapt itself to the consumption of steam. Thus it had to be determined for all specific weights coming under consideration, and for this purpose the following arrangement was made: A meter, finished and ready for use, was fixed in a steam conduit and the steam passing through was condensed in a cooling-apparatus and weighed. In this manner W was exactly determined; S and γ follows from the diagram of the meter and in the equation $W = S \cdot V \cdot \gamma$ only the quantity V was wanting. This can be obtained by dividing G by $S \gamma$. In this way the velocities for the specific weights

of steam were determined for the different pressures from atmosphere to atmosphere by a large number of experiments. The velocities corresponding to the intermediate specific weights were found by interpolation. Now by multiplying the three quantities, S , γ and V , each required quantity of steam may be ascertained.

As it would be somewhat cumbersome to carry out the calculation for each observation, it may be simplified by tabulating the quantities of steam corresponding to each square mm. of increase of section and for the specific weights from 1/10 to 1/10 of an atmosphere.

The average pressure and the average distance of the sectional line from the base-line being found from the diagram by means of a planimeter, the consumption of steam per mm. pressure during 12 hours can be determined with the aid of the table. This number need only be multiplied by the found distance of the sectional line in order to obtain the total consumption of steam in kilos. for 12 hours.

So far we have spoken only of saturated steam, but by means of the meter superheated steam may be measured as well, without introducing any complication. Only special tables are needed for superheated steam, the specific weight being not only dependent on the pressure but on the temperature as well.

Though the chief use of the instrument is to ascertain the quantity of steam consumed, yet the way it throws light on the manner in which the steam has been consumed by registering the consumption continuously must be mentioned. For further explanation I refer to the enlargement of an original diagram from one of the

plants of the Farbenfabriken. From the curves of the diagram it will be seen that 4 operations have been performed, the duration of which in every case amounted to somewhat less than 2 hours, with the exception of the last one where the workman left the steam valve open unnecessarily for $\frac{1}{2}$ hour. Between 10 and 11 o'clock an extraordinarily high consumption of steam attracted attention and an enquiry as to its cause was made. It was found that at this time steam had been used for warming water, although sufficient warm water was available from another plant. A large number of such characteristic diagrams could be shown but this one may be considered sufficient for explaining the economical value of the instrument, as it informs the manager about the working of his men, and enables him, in case of need, to prevent any waste of steam.

The accuracy of the meter is excellent. The Farbenfabriken guarantee accuracy within the limit of about 3 per cent. The instruments are carefully tested before leaving the workshop and the limit of ascertained error, as a rule, does not exceed 1 per cent. The accuracy of the meter remains unchanged, for the various parts, namely the hollow cone and the disc upon which the accuracy depends, are scarcely subject to any wear and tear, the velocity of the steam passing through the apparatus being so low (on the average about 30 m.

that it does not have any destructive effect on the metal parts. Steam meters, the accuracy of which depends on springs or upon fixed quantities of mercury on the other hand very soon suffer a change.

This apparatus was invented in 1902,* but hitherto it has only been used in the factories of the Farbenfabriken.

The reliability of the meter having been established by six years' practical use, the Farbenfabriken determined, at the beginning of the last year, to offer it for sale. The somewhat large number of apparatus delivered during the short period proves that other factories also have obtained good results with the apparatus. Therefore I am not saying too much if I claim for this steam meter that it constitutes a valuable improvement in measuring the consumption of steam.

DISCUSSION.

The CHAIRMAN said that it was hardly necessary to emphasise the usefulness of such an apparatus as this. One of the chief items in the cost sheet of a works was that of steam; and hitherto there had in many works more or less guess work as to the amount of steam used in certain operations. He could recall experience of his own in trying to ascertain how much steam was required to boil a ton of soap, as to which the most divergent ideas obtained, it being usual to look into the bills for coal at the end of the year and divide the sum total by the number of tons of soap made. He himself had tried, by a series of elaborate experiments, analyses, and calculations to arrive at reliable figures. All this trouble would have been avoided by using an automatic apparatus of the kind shown. Again, in distilling glycerin, he wished to ascertain how much superheated steam was required to produce one ton of finished glycerin. Many years ago, he devised ways and means to condense the steam specially and weigh it; moreover all the glycerin waters had to be analysed. This method was accurate, but was very troublesome. In calculating the cost of the steam required in different departments applied from a range of boilers, guess work was still more prominent. In one works with which he was acquainted, the time was noted during which the steam valves were open, and the number of turns and parts of a turn to which they were open were counted, then by calculating total cost of the steam produced in the works, some kind of guess work the manager persuaded himself that he had arrived at the figure to be charged to each different plant for steam. The Chairman then asked whether the condensed water, or the pulverised water carried away with the steam, might not be calculated as so much steam. It would be, of course, possible to put baffle in so as to trap and lead away the condensed water. In chemical works this might be necessary. He remembered a case where he had guaranteed for evaporating apparatus a certain amount of steam for evaporation. During various stages of the evaporation the partly concentrated liquid had to be boiled up, for which a certain amount of steam was required. Of course the case of a guarantee it was to the advantage of the over-scrupulous people to send through the pipes much wet steam as possible, so as to increase, to the detriment of the guarantor, the amount of water to be evaporated off. In a case like that an extra condensed water meter would have to be inserted, which, of course, did nothing to do with the principle of the present steam meter. He would therefore like to ask whether the condensed water, or that carried away with the steam, might not be calculated as so much weight of steam. The cost of the instrument as compared with other apparatus, say that of Parenty, which he understood worked with mercury, and had come into somewhat general use on the Continent, was also of importance.

Mr. E. HATSCHKE said it was always a matter of very great difficulty to get a paraboloid correct, and he understood that the exactness of this instrument depended entirely upon the paraboloid being right for that parameter. The turning of a paraboloid was found to be

a very difficult problem in connection with mirrors; but of course in a parabolic mirror the apex of the paraboloid only was used, which was even more difficult. However, even a truncated paraboloid, such as was used here, was extremely difficult to make correct; whilst, if it was not correct, it was useless if used with constant ordinates on the recording drum. He would therefore like to know what means were taken to get this correct; or, if not, what means could be taken to calibrate the drum?

Mr. G. N. HUNTLY asked what was the capacity of the meter, *i.e.*, how many gallons of water per hour, in the form of steam, would pass through it. He was also interested in the question suggested by the Chairman as to how far the moisture in the steam would affect the matter, because even a water drip could not ensure steam going through dry. In boiler trials one of the greatest difficulties was to determine the exact dryness of the steam. The density of the steam was one of the factors, and therefore some means to determine the exact wetness of the steam seemed essential to the practical working of the system.

Dr. E. FEILMANN asked if there was not a certain amount of inaccuracy in passing the steam through what would be in the case of small quantities a comparatively narrow slit. One would expect a certain eddying action round the slit which would alter the difference of pressure on the two sides. He did not know whether it would be sufficient to practically affect the accuracy of the registration, but it would be interesting to have some information upon that point.

Mr. J. W. HINCHEY said that a number of experiments had been made upon gases flowing through pipes, and the results went to show that it was necessary to guide the gases in the direction you wanted. It seemed to him that the question raised by Dr. Feilmann would be met by providing a guide at the edge of the disc to prevent eddies. In designing the apparatus a "feeling" for the flow of the steam had not been present at all. The notion apparently was that steam turned corners as easily as possible. But in measuring the velocity of gases passing fans and so on, it had been found necessary to provide a disc guide at the end of the tube inserted in the stream to overcome these eddy currents. Had the edge of the disc been experimentally modified for this purpose, and could they not by that means get rid of some part of the three per cent. error which is said to exist?

Mr. FRANK HEMINGWAY asked whether any slight mechanical defects in construction might not be overcome by carefully calibrating with dry steam before the instrument was sent out.

Mr. J. C. PHILIP said that in constructing a paraboloid of revolution for search-light mirrors a very ingenious method had been used for cheaply reproducing the exact shape of an accurately made and costly pattern-paraboloid. This method might be adopted for preparing paraboloids required in the instrument under discussion. A convex parabolic mould was carefully made of glass and the outside was accurately ground to the exact theoretical shape desired, and on this a silver film was deposited chemically. On that again copper was electrolytically deposited to any desired thickness and the metal paraboloid was afterwards removed from the glass by slightly warming; this separation occurred readily owing to the difference in thermal expansion between the glass and the metal. The concave paraboloid of revolution thus obtained was shown by optical methods to be of extraordinary accuracy in the case of mirrors, equal in fact to that of the pattern paraboloid. The method was described in 1898 in a paper by Mr. Cowper-Coles published in the *Journal of the Institute of Electrical Engineers*, Vol. 27, p. 99.

Dr. L. T. THORNE asked what range of work they could get in this meter. Of course it would depend on the size of the truncated cone. But could they in practice get a considerable range in the quantity of steam measured in one meter?

Mr. KUNKE, in reply, said the condense water was not calculated as steam. The casing in which the hollow truncated cone was placed acted as a separator for the water, and the water which collected in the bottom part of the casing was carried away by a trap. The

Farbenfabriken manufactured at present three different sizes of meters, for pipes with a diameter from 60, 100, and 150 mm., which could be used for any size of piping without affecting the accuracy of the meter. The prices were about the same as those of other meters obtainable in the market. The parabola was made on the lathe; that had, of course, to be done with greatest care, as the exactness of the meter depended on this point. It was impossible to test the accuracy of the meter by a measuring instrument, but the cone was tested in the following way:—The steam meter is fixed behind a normal meter which has been tested in all positions of the disc by condensing the steam which has passed through and weighing the water. Through both instruments the same quantity of steam is passing and consequently the positions of the discs should be the same with all quantities of steam. Whenever it is impossible to obtain exact agreement by changing the weight, the cone is discarded as useless.

The following table shows the maximum of steam passing through in 1 hour for the three different kinds of meters:—

	At 1 atm.	At 2 atm.	At 3 atm.	At 4 atm.	At 5 atm.	At 6 atm.
m.m.	Kg.	Kg.	Kg.	Kg.	Kg.	Kg.
60 ..	640	775	885	985	1070	1140
100 ..	1275	1545	1765	1965	2135	2280
150 ..	2475	2995	3420	3805	4145	4455

	At 7 atm.	At 8 atm.	At 9 atm.	At 10 atm.	At 11 atm.	At 12 atm.
m.m.	Kg.	Kg.	Kg.	Kg.	Kg.	Kg.
60 ..	1225	1295	1360	1420	1480	1535
100 ..	2445	2585	2715	2840	2960	3070
150 ..	4740	5010	5270	5520	5740	5965

In reply to Mr. Hinchley, as the disc could freely move up and down, it was probable that no rotatory motions existed, and if they did exist, they were harmless, as the velocity of the steam was constant at all positions of the disc. The first experiments were made with an apparatus in which the disc was formed like a bell. It was found that the velocity of the steam was much higher in the upper positions of the bell than in the lower ones. Probably rotatory motion must be held to account for this appearance.

Meeting held at Burlington House on Monday, June 7th, 1909.

DR. J. LEWKOWITSCH IN THE CHAIR.

THE COLORIMETRIC DETERMINATION OF LEAD IN THE PRESENCE OF IRON WITH SOME NOTES ON THE PREPARATION OF LEAD FREE REAGENTS BY COPRECIPITATION WITH FERRIC HYDROXIDE.*

BY JOHN M. WILKIE, B.Sc., A.I.C.

The determination of minute traces of lead dates from the reading of Warington's paper (this J., 1893, 97). His work concerned itself with citric and tartaric acids and showed that lead could be determined colorimetrically with considerable accuracy in alkaline solution using ammonium sulphide as precipitant. He insisted on the fact that comparisons must be made between citrate or tartrate solutions and not between one of these and water. To avoid interference due to iron, he advised that the "solution of tartaric or citric acid, made alkaline with ammonia, should be treated with a few drops of potassium cyanide and heated to near boiling."

This conversion of iron to soluble complex cyanides

not affected by alkaline sulphide had been previously recommended by Teed (Analyst, 1892, 142), as follows:—"Iron does not at all interfere with the test. If an iron salt is added to lemonade, for instance, and made alkaline with ammonia the iron is kept in solution by the tartaric acid, and on addition of the potassium cyanide is converted into potassium ferrocyanide or ferricyanide as the case may be. To liquids not containing tartaric acid it is easy to add a little in the event of iron being present."

Teed, apparently, considered that the tartaric acid merely kept iron in solution, and he drew no distinction between ferrous and ferric iron. Citric acid also forms complexes with iron salts. Teed assumes that the complex does not hold the iron so firmly as to inhibit its complete conversion into ferrocyanide or ferricyanide. Experiments were made to see whether this was so, and also if small amounts of iron were so firmly held as not to react to alkaline sulphide in the absence of cyanide. The mode of testing was as follows:—12 grms. of tartaric acid (in the form of a stock solution 2 c.c. of which contains 1 gm. acid) were placed in a Nessler cylinder with 0.05 mg. metallic lead (in solution as nitrate: 1 c.c.=0.1 mg. of lead) and a slight excess of .880 ammonia, and the volume after cooling was adjusted to 50 c.c. Five similar tests were prepared to which were added, before the addition of ammonia, ferrous sulphate, in amounts respectively equivalent to 0.00, 0.05, 0.10, 0.15 and 0.20 mg. of metallic iron.

The tints developed on adding 3 drops of a sodium sulphide solution to each were practically indistinguishable. Larger volumes of ferrous iron however developed colorations corresponding to much more lead than that actually present. Identical tests were next prepared, but to each of these was added 1 c.c. of 10 per cent. potassium cyanide after addition of the ammonia. The maximum amount of iron now coverable was about 1 mg. With citric acid similar results were obtained, but the tints in presence of iron were in all cases somewhat different from those obtained in the absence of iron.

When ferric iron was substituted for ferrous iron much more interesting results were obtained. Taking citric acid first, it was found that with the addition of as much as an amount of ferric iron as 0.10 mg. a persistent yellow coloration was developed which did not disappear on making alkaline with ammonia and adding potassium cyanide. Boiling the alkaline solution discharged the colour to some extent, but on adding sodium sulphide to the cooled solution the tint produced was quite yellow and not comparable with that produced by the same amount of lead (0.05 mg.) in the absence of iron. Tartaric acid behaved somewhat similarly but the tints did not deviate so widely from the normal. That the colorimetric determination of lead in citric and tartaric acid was made impossible by such trifling amounts of ferric iron was so surprising that attention next was turned to inorganic salts. No work appears to have been published on the applicability of the alkaline sulphide method to solutions free from tartaric acid. Hill (Chem and Drug., 1905, I., 388; this J., 1905, 901), while rendering an important service by showing that lead free standards in some cases were not absolutely essential, assumed that tartaric acid played no special part. Unmindful of the fact that ammonia quantitatively precipitates iron from its inorganic solutions, he determined lead in inorganic salts by adding sodium sulphide after addition of ammonia followed by potassium cyanide. He also deprecates heating with the potassium cyanide. He quotes an experiment, confirmed by myself, for ferric iron, to show that in the presence of 0.05 mg. of iron the process thus simplified hopelessly breaks down, that is to say, the colour of the finely divided ferric hydroxide quite covers that due to the lead sulphide. Of course, this difficulty could be removed by filtration through a close textured filter, but ferric hydroxide quantity drags down with it any lead present in solution. The question, now to be solved, was whether ferric iron in amount proportionate to the lead normally occurring in pure chemicals, had the same effect. The substance worked on was sodium chloride and potassium nitrate both of which contained negligible amounts of lead (less than 5 parts per million) and still smaller amounts

* Taken as read.

iron. The mode of working was very similar to that already described.

Experiments 7, 8, and 9 were repeated by a colleague, except that the solution of potassium nitrate containing added iron and lead was cooled in each case before adding the ammonia and potassium cyanide. Precisely identical results were obtained. Experiments were next made to show that:—

- 1. Potassium cyanide plays no special part in the coprecipitation of lead by ferric hydroxide, bearing in mind that lead cyanide is an insoluble salt.
 - 2. Subsequent heating with potassium cyanide has no appreciable solvent action.
 - 3. The precipitation of lead is independent of a high acid concentration.
- A mixture of 0.05 mg. lead and 0.10 mg. ferric iron, used in the forms already described, was diluted to a volume of 50 c.c. with cold distilled water, excess of ammonia added and the whole filtered through a close textured filter. No lead was found in the filtrate, thus supporting statements 1 and 3.

A similar experiment was next made in which 1 c.c. of 10 per cent. potassium cyanide solution was present, after excess of ammonia had been introduced, and the whole boiled several minutes. No visible diminution in the amount of the ferric hydroxide occurred and the cooled filtrate showed no lead to sodium sulphide.

Experiments were made with magnesium sulphate as a type of salt of a metal having an insoluble hydroxide. Similar results were obtained, but to insure complete recitipation of lead about ten times as much iron must be added—limited amounts of ammonia being used.

The futility of professing to adopt Teed's process, while omitting tartaric acid, is thus demonstrated (*cf.* an anonymous correspondent in the *Pharm. J.*, 1908, I, 181). The direct bearing of the above on the preparation of lead re chemicals must not be overlooked—all that is necessary

to add a minute amount of a ferric salt (chloride), make distinctly alkaline with ammonia, and filter out the coprecipitated hydroxides. This process is now being used for the preparation of lead-free ammonium chloride. In this connection it has been puzzling to account for the fact that commercial salts, *e.g.* ammonium chloride, sodium sulphate, etc., often show greater freedom from lead than the purer salts. In the light of the above the reason is obvious. It is also curious to reflect that the U.S. Pharmacopeia recommends testing for heavy metals in ferrous sulphate by adding hydrogen sulphide to the filtrate obtained after precipitation of iron as ferric hydroxide.

Since in the presence of ferric iron Teed's process breaks down for citric and tartaric acids, and in the simplified process of Hill entire loss of lead may occur, seemed best to now consider whether the method was heretofore wrong or only in points of detail. For quantitative conversion to soluble complex cyanides it is obvious that precipitation of iron should take place in intimate contact with the potassium cyanide—and at if this were done the tartaric acid might be safely omitted. Preliminary experiments showed that an essential difference existed between ferrous and ferric iron. With the latter the solution always became colourless on treatment with potassium cyanide—no matter to surprise considering the high tinctorial power of

potassium ferriocyanide. Consequently, the first series of experiments was performed with ferrous iron (ferrous sulphate). Brief consideration will show that intimate precipitation of ferrous hydroxide in the presence of potassium cyanide may be effected in one of two ways:—either the acid solution of the iron salt may be added to the potassium cyanide or the potassium cyanide to the iron solution. If the acid is present in considerable excess the alkalinity of the potassium cyanide may be increased by addition of ammonia; in all cases the liquid must finally possess a strong alkaline reaction.

A solution of ferrous sulphate was made of which 5 c.c. contained 1 mg. of ferrous iron, and 0.2 c.c. normal sulphuric acid. In one experiment 1 c.c. of this solution was diluted to 40 c.c., 1 c.c. of 10 per cent. potassium cyanide added slowly with constant rotation followed by 0.5 c.c. 880 ammonia and the colourless solution adjusted to 50 c.c. On addition of sodium sulphide no colour was developed and the solution was practically water white. The experiment was repeated four times, adding .05 mg. lead in each case and 0.05, 0.10, 0.15, 0.20 mg. of ferrous iron respectively.

In all cases colourless solutions were obtained which on addition of sodium sulphide gave perfectly normal colorations. Ferrous iron in larger quantity was next added, viz.:—0.25, 0.50, 0.75, 1.0, 2.0, 3.0, 4.0 mg.

In all these the solution, after addition of the ammonia, had a slight colour which disappeared on heating, but with amounts larger than 0.50 mg. it was found better to mix the ammonia with the cyanide before adding as otherwise a certain amount of Prussian blue was formed.

To extend the method to ferric iron necessitates preliminary reduction to the ferrous condition. Any reducer selected must be efficient, easily obtainable lead free, and not precipitable by alkaline sulphide. Sodium sulphite ($\text{Na}_2\text{SO}_3 \cdot 7\text{H}_2\text{O}$) fulfils most of these requirements, and the mode of using is simplicity itself. 1 c.c. of a saturated aqueous solution is added to the salt solution to which has previously been added 4 drops 1:16 hydrochloric acid—heat is then applied until the colour due to ferric iron suddenly bleaches—to the colourless solution is added a mixture of 1 c.c. 10 per cent. potassium cyanide solution and 2 c.c. 880 ammonia. The whole is again heated and gently boiled, if necessary, until quite colourless, cooled, and treated with sulphide in the usual manner.

The experiments detailed for ferrous iron were now repeated with ferric iron reduced with sodium sulphite as described. Solutions containing 0.05 mg. lead and 0.05, 0.25, 0.5, 0.75, 1.0, 2.0, 3.0, 4.0 mg. of ferric iron respectively gave quite colourless solutions which on addition of sodium sulphide were indistinguishable from each other and from solutions containing the same amount of lead (0.05 mg.) but no iron. The method thus modified worked satisfactorily in presence of the ordinary inorganic salts. Amongst others worked on were potassium, sodium and magnesium sulphate chloride and nitrate, phosphoric acid and ammonium and sodium phosphates—the mode of working in all cases being to add 4 mg. of ferric iron to the maximum amount of any particular salt permitted by its solubility. In the case of salts like ammonium phosphate, for instance, a greatly increased amount of acid must be added to keep iron in solution—in this particular case 7.5 c.c. of 1:16 hydrochloric acid was added to 12 grms. of the salt, a proportionately increased amount of ammonia being demanded.

In view of the extremely unsatisfactory results obtained with citric and tartaric acids these were again examined. It seemed not unlikely that here again better results would be obtained by adding the potassium cyanide direct to the solution of the acid and not after previous neutralisation with ammonia, as from previous work it was thought that the iron would then be more reactive.

It was found possible to add several milligrams of ferrous iron just as satisfactorily as in the absence of the organic acid. But in the case of ferric iron, the greatest difficulty was experienced in finding an effective reducing agent. Sodium sulphite failed to discharge the colour produced by ferric chloride in presence of citric acid. At last, sodium thiosulphate was found to

act perfectly. The actual details of one of the tests may be given here.

12 grms. of citric acid, 1 mg. of ferric iron, 0.05 mg. lead were placed in a Jena flask and water added so as to give a volume of about 35 c.c. 2 c.c. of $N/10$ sodium thiosulphate was added and the whole heated to incipient boiling and the flame removed. After about 5 minutes the solution became perfectly water-white and to it was immediately added 1 c.c. 10 per cent. potassium cyanide and then excess of 880 ammonia (13 c.c.) and the whole gently boiled until colourless.

With tartaric acid the ammonia must be added in slight excess only or a slightly coloured solution will be obtained even in the absence of appreciable amounts of iron.

Theoretically four mg. of iron require 28 mg. of potassium cyanide for conversion to potassium ferrocyanide whereas 100 mg. (about three and a half times this amount) were regularly used. In one experiment, keeping the iron constant, the cyanide was cut down to one half and successful results were obtained if the cold acid ferrous solution was added to the potassium cyanide mixed with sufficient ammonia to give finally a distinctly ammoniacal solution. As considerable dexterity was required to obtain satisfactory results no further experiments were undertaken with amounts of cyanide nearer to theory. In fact for convenient working the ratio of 25 to 1 should not be diminished. A few words may be added on the value of sodium thiosulphate in the reduction of iron for work of this kind. In my experience complete reduction occurs only in acid solution, but unlike sulphurous acid or sulphites the action is not retarded in the presence of large amounts of strong acids, etc. Its reducing action depends upon its conversion to tetrathionate in accordance with the following equation which is practically quantitative under the prescribed conditions. $2\text{Na}_2\text{S}_2\text{O}_3 + 2\text{FeCl}_3 = \text{Na}_2\text{S}_4\text{O}_6 + 2\text{FeCl}_2 + 2\text{NaCl}$.

This amount very little in excess of theory effects complete reduction but considerable latitude in the amount added is given without precipitation of sulphur or lead sulphide occurring, provided the cyanide and ammonia be added successively as soon as the solution becomes colourless. A certain amount of this flexibility is possibly due to the solvent action of sodium tetrathionate on nascent sulphur. Its unique value in the presence of large amounts of citric and tartaric acids has been already referred to.

In conclusion a number of problems concerning the availability of the alkaline sulphide method of colorimetrically determining lead in the presence of iron have been investigated. An essential difference has been shown to exist between ferrous and ferric iron, ferrous compounds alone being capable of conversion by potassium cyanide to colourless substances not affected by alkaline sulphide. Ferric hydroxide has the power of adsorbing lead; and with many salts if the proportion of iron exceeds twice the lead present, precipitation is complete and no lead is left in solution. This property of ferric hydroxide when available greatly simplifies the manufacture of lead free chemicals. Teed's process requires radical modifications: ferric iron if present must be reduced to the ferrous condition and precipitation of ferrous hydroxide must occur within the sphere of action of the potassium cyanide. It is only when these two essential conditions are attended to that the addition of tartaric acid becomes superfluous. Sodium thiosulphate possesses special features as a reducing agent in work of this kind.

The author desires to express his indebtedness to Messrs. Boots, Ltd., for the use of their laboratory in which the work was carried out.

THE QUINONOID SALTS OF THE PHTHALEINS AND THE CAUSE OF COLOUR IN THE TRIPHENYLMETHANE SERIES.*

BY ARTHUR G. GREEN, M.Sc., F.I.C.

In a recent series of investigations upon the phtaleins in conjunction with P. E. King† strong evidence has been

adduced in favour of the quinonoid structure of the coloured salts and ethers of these compounds. This has since received further support from Kurt Meyer and Hantzsch* and from Richard Meyer and Marx.† There still remain, however, some points which require further elucidation. One of these is the remarkable difference in colour between the alkali salts of the phtaleins and their quinonoid dialkyl esters (bluish red to violet in the first case and orange in the second). This difference in shade and intensity of colour would seem to indicate that the structure in the two cases cannot be entirely alike. Another point which is difficult to explain is the fact that the monoalkylphtaleins (lactone ethers) do not form coloured alkali salts, that is to say the substitution of hydrogen in one of the hydroxyl groups either of phenol or of quinol-phtalein suffices to inhibit the formation of coloured salts with metals. A coloured salt of the type:

does not appear to be capable of existence. On the other hand, salts of the type:

are deeply coloured (violet red). These observations are exactly comparable with those made earlier with tetrabromophenolphthalein by Nietzki and Bueckhardt. They also stand in complete accord with analogous observations made in other branches of the triphenyl methane group by v. Baeyer and others. For instance benzaurine (oxyfuchson) (I.) gives deep red alkali salts whilst fuchson (or diphenylquinomethane) (II.) is only orange coloured:

That this difference of colour is not due simply to the occurrence or non-occurrence of salt-formation is shown by the observations already cited and by the fact recently ascertained by v. Bayer that, contrary to the original statement of v. Pechmann, the oxydiphenylphtalide:

dissolves in alkalis with the formation of a colourless salt.

Similar relationships also hold good amongst the amidated derivatives. Thus, although the anhydrid of paraamidotriphenylcarbinol (fuchsonium chloride) is orange, a true dyestuff is not produced until at least one amido group is introduced into the para position of a second benzene nucleus:

The general rule is therefore established that for the production of deeply coloured compounds (true dyestuff of the triphenylmethane series, it is necessary to have an amido or unsubstituted hydroxy group in the second

* Ber., 1907, 40, 3484. This communication, though appearing on an earlier page of the same issue as ours, bears the date July 26th, whilst our paper is dated July 19th. Priority must therefore be accorded to us for those observations which are contained in both papers.

benzene ring, or, employing the language of Witt's original colour hypothesis, an auxochrome group is required in addition to the chromophore to render the coloured compound a dyestuff.

In explanation of these facts a remarkably illuminating theory has recently been put forward by v. Baeyer.* The latter suggests that the deep colour of the triphenylmethane dyestuffs as distinguished from the far less intense colour of the parent quinonoid compounds is due to an oscillation of the quinonoid linking between the two benzene nuclei, accompanied by a corresponding opposite oscillation of the ion of the salt forming group (e.g., Na or Cl) from the para oxygen or nitrogen of one ring to that of the other. This condition in the case for instance of Malachite Green may be represented thus:—

This theory, which seems eminently capable of extension to other groups of dyestuffs, gives for the first time a clear conception of the function and mode of action of auxochrome groups, since in accordance therewith the latter may be defined as groups capable of becoming part of a quinonoid configuration. Even such obscure cases of colour intensification as the relationship of the quinhydrone to the quinones and of Wurster's colour salts to the quinonimides may possibly receive thereby a simple explanation.† It should be observed that these formulae are not intended to indicate an equilibrium mixture of two forms, but a dynamic condition of the molecule which no single formula can exactly represent.

In the triphenylmethane group the theory would likewise seem to give an explanation of another phenomenon which has also been especially studied by v. Baeyer.‡ This is the remarkable accumulation of basicity in the molecule brought about by the introduction of amido or methoxy groups. Thus it has long been known that the basicity of rosaniline greatly exceeds that of the mono- and di-amidated triphenylcarbinols, and of the ordinary amine bases in general (formation of carbonates, etc.). v. Baeyer has shown that the increase of basicity brought about in triphenylcarbinol itself by introduction of one, two, or three para-methoxy groups is approximately represented by the numerical ratio 6.5 : (6.5)² : (6.5)³. If we accept v. Baeyer's hypothesis of oscillatory quinonoid structure it appears that this high basicity of the dyestuff bases may be due to all the amido groups taking part in turn in the salt formation, so that in the hydrochloride of rosaniline for instance a single chlorine ion is held by three amido groups. In a similar manner we may refer the remarkable acidity of the phenolic hydroxyl groups in phenolphthalein (which is shown by our experiments to be greater than that of the carboxyl group) to the oscillation of the metallic ion in the coloured alkaline salts between the two oxygen atoms, which hence hold it more firmly.

* Ann., 1907, **354**, 164. v. Baeyer in illustrating this theory makes use of the old Graebe formula for quinone. This is obviously unnecessary and is open to the objection that it restricts the employment of the theory to para compounds. Ortho dyestuffs of the general form:

would upon the Graebe type be only capable of this one configuration, whilst upon the Fittig type they would be capable of two:

Many facts relating to the dyestuffs of the azonium group speak in favour of such a wandering of the quinonoid bonds.

† Cf. Willstätter and Piccard, Ber., 1908, **41**, 1458; also Acree, Am. Chem. Jour., 1908, **39**, 534 and 789.

‡ Ber., 1902, **35**, 3020; 1905, **37**, 1158.

This brings us to the consideration of another point, namely, the connection of salt formation with the manifestation of intense colour. Although many coloured bodies are known which are not salts, it has been recognised from a very early date (cf. Witt) that salt formation is frequently accompanied by great intensification of colour. Thus in the triphenylmethane group the quinonimide bases corresponding to Malachite Green, Aniline Blue, Victoria Blue, Doebner's Violet, etc., are all yellow or orange or brownish red of no great intensity. Only on conversion into a salt is the intense colour of the true dyestuff called forth. In the apparent exceptions in which the base has the same intense colour as the dyestuff the base has the structure of a quinonimmonium hydrate to which the same considerations will apply as to the dye-salt itself. V. Baeyer has moreover noted the almost exact correspondence of the absorption spectra of the alkaline salts of the hydroxylated compounds with the acid salts of the amidated compounds. Thus an aqueous solution of the sodium salt of aurine has the same crimson red colour as the hydrochloride of rosaniline. Upon the ordinary formulae for these compounds,

the cause of this analogy is not apparent, since in the first instance the non-quinonoid nucleus, in the second instance the quinonoid nucleus is engaged in the salt formation. This distinction, however, disappears when we regard the Na or Cl ion as oscillating constantly between the two groups, for then both groups may be considered as engaged in the salt formation. In stating his theory v. Baeyer appears to regard this movement of the acid or metallic ion as only a necessary concomitant of the oscillation of the quinonoid bonds, but the question arises whether there are not good grounds for regarding it as the primary cause of the quinonoid oscillation, for otherwise there seems no reason why the latter should not occur also in the case of the free amido or hydroxy compounds. The assumption that this swinging ion is the primary cause of the quinonoid oscillation enables us to arrive at a complete theory of the influence of salt formation upon colour. At the same time it offers a satisfactory compromise to the upholders of the theory of the dependence of colour upon ionic dissociation.

In full accord with the theory here formulated are some observations recently made by P. E. King and myself upon the basic analogues of phenolphthalein. The diamidodiphenylphthalide is not readily obtainable, but the corresponding tetramethyl derivative (the dimethylaniline phthalide):

is easily prepared according to Fischer's method by condensing phthalic anhydride with dimethylaniline in presence of zinc chloride.* We thus obtained it in colourless prismatic crystals which melted at 190°–191° C. It would be expected from the above considerations that just as the addition of alkalis to phenolphthalein calls forth an intense colour formation, so should the addition of acids to the dimethylaniline phthalide. Fischer however states that the salts of this compound are colourless and we find in fact that the base dissolves both in dilute and in strong acids without any production of colour. Nevertheless the formation of intensely coloured salts can be brought about by adopting certain specific conditions. If for instance a fragment of aluminium chloride be added to the alcoholic solution of the base, the solution at once assumes a deep violet-blue colour. That this is due to formation of the quinonoid salt,

and not to any specific action of the aluminium chloride is proved by the fact that the same effect, though less

* Ann., **206**, 83. Cf. also Haller and Guyot, Compt. Rend., **119**, 205.

intense, is produced by adding formic acid or a single drop of hydrochloric acid to the alcoholic solution. The colour disappears on adding more acid, a fact which is exactly comparable to the decolorisation of the alkaline phenolphthalein solution by an excess of caustic alkali. The blue solution is also decolorised on dilution with water. A further analogy to phenolphthalein is exhibited upon etherification. Just as the alkaline salts of phenolphthalein ester are much less prone to hydrolysis (decolorisation by excess of alkali) so also a dyestuff much stabler to water and acids is obtained by conversion of the dimethylaniline-phthalein into its ester. This has been ascertained qualitatively by etherification of the phthalein with dimethylsulphate, although owing to difficulties in finding the proper experimental conditions for complete alkylation, the dyestuff has not yet been prepared in a sufficiently pure state for analysis. This dyestuff is probably identical with that described in Ger. Pat. No. 98,863 of 1897 and obtained by condensation of the half-aldehyde of phthalic acid with dimethylaniline, etherification of the leuco base and oxidation with lead peroxide. The product is described as a dark blue powder which dyes silk and cotton in bluish-green shades.

All these relationships are well explained if we assume that both in the case of the dihydroxy and of the diamido derivatives of the phthalein group the oscillation of the quinonoid bonds renders the molecule especially prone to hydration. This tendency would be augmented when a free carboxylic group was present, since such a group would tend to prevent reversion of the carbinol to the quinonoid type by formation of the stable lactone ring with the carbinol hydroxyl. In the case of the carboxylic esters this lactone formation would occur with greater difficulty since it would necessitate the elimination of alcohol. These considerations explain the occurrence of complete decolorisation of the phthalein salts by alkalies or acids in contradistinction to the more or less partial decolorisation of the ordinary triphenylmethane dyestuffs by excess of these reagents. In the case of the dyestuffs an equilibrium is established and complete decolorisation only effected slowly and with difficulty.

One further point in agreement with v. Baeyer's theory is the fact observed by Green and King that the orange quinonoid esters of phenolphthalein give rise with acids to oxonium salts of a pinkish red colour. The formation of oxonium salts therefore influences the colour in a similar direction to the formation of alkaline salts, though much less intensely. Analogous observations have been made by v. Baeyer upon the methoxy derivatives of triphenylcarbinol, though explained by him in a different manner. In all these cases it appears probable that the deepening of the colour is due to an oscillation of the quinonoid bonds between the two benzene nuclei, this fluctuation being set up by the movement of the acid or basic ion.

We will now consider the bearing of these views upon the case of quinolphthalein. Here, to judge from the behaviour of the compound and its ethers, a condition of things exists which is closely similar to that occurring with phenolphthalein, and this in spite of the fact that a paraquinonoid configuration is impossible. Being disinclined to assume a metaquinonoid structure, Green and King suggested for the alkali salts of quinolphthalein the formula (I), thus representing them as anhydrides of an oxonium hydrate (II):

This formula, although at first sight appearing to explain the need of two hydroxyl groups for the production of coloured salts, does not seem on closer consideration entirely satisfactory, for it gives no adequate explanation for the non-existence of a coloured sodium salt of the monomethyl ether in the form:

Green and King based the above orthoquinonoid formula for the quinolphthalein salts upon the presumption of an analogous configuration to the corresponding acid oxonium salts, to which they proved an orthoquinonoid structure must certainly be assigned:

All doubt with regard to the latter has now been removed by the preparation of the quinonoid ester oxonium salts of the parent compound fluorane and of its homologue.* These simple oxonium salts of fluorane ester for which an orthoquinonoid structure is alone possible, are deeply coloured yellow compounds of considerable similarity to the quinolphthalein oxonium salts, but possessing inferior stability and a less intense colour.

The assumption of a metaquinonoid structure for the alkali salts of quinolphthalein:

is now definitely advocated by R. Meyer, and gains some support from the recent investigations of Hantzsch upon the chromo salts of nitrophenols. Thus the potassium salt of the 4:6-tribromo-3:5-dinitrophenol exists in two forms, a yellow and red form, to both of which Hantzsch assigns a quinonoid structure.† It may also be noted that amongst the meta-substituted derivatives of triphenylcarbinol v. Baeyer has frequently observed the occurrence of coloured salts. Thus both the metadimethoxy- and the metatrimethoxy-triphenylcarbinol dissolve in concentrated sulphuric acid with a deep bluish red colour forming coloured salts which only differ from those of the para series in being decolorised by alcohol.‡ Although v. Baeyer regards these manifestations of colour in the meta series as differing entirely in kind from those in the para series, his grounds for this belief are not very convincing and it would seem conceivable, even without admitting the independent existence of meta quinones, that an unstable metaquinonoid phase might be possible in these compounds. This phase might indeed be rendered more permanent by the oscillation of the quinone structure between the two benzene nuclei. Such a kinetic condition of the molecule would be very analogous to that suggested for the phenolphthalein salts, and hence would explain their remarkable similarity. Opposed to this assumption is however the fact that it necessitates a change of type from ortho- to meta-quinonoid (a change that is to say to a less stable configuration) when the orange red oxonium chloride of quinolphthalein or of its ester is converted by alkalies into the respective violet alkali salts. On the whole it appears that the facts at our disposal may be best reconciled by the assumption for the violet salts of a kinetic ortho-quinonoid structure as represented by the formula:

Department of Tinctorial Chemistry,
University of Leeds.

* Ber., 1908, 41, 1434.

† Ber., 1907, 40, 339. The existence of two series of coloured salts of the nitrophenols might, it would seem, be explained more simply than in the manner suggested by Hantzsch. In a quinonoid nitrophenol salt the double union of the N to the C should render the compound capable of existence in two geometrically isomeric forms:

In each case the Na ion may be regarded not as fixed to the nitro group, but as oscillating between this and the phenolic oxygen. The difference in colour between the two forms may thus be attributed to the longer path which the metallic ion must traverse in the one case compared with the other.

Meeting held at Manchester on Friday, May 7, 1909.

MR. W. H. COLEMAN IN THE CHAIR.

THE ACTION OF CAUSTIC SODA LYE ON COTTON.

BY JULIUS HÜBNER, M.Sc. TECH., F.I.C., AND F. TELTSCHER, PH.D.

The extent to which caustic soda is absorbed by cotton from strong lyes, and the degree of tenacity with which the absorbed soda is retained by the fibre, were first studied quantitatively by J. H. Gladstone (J. Chem. Soc., 5, 17). Gladstone's method of examination consisted in immersing 20 grm. lots of cotton in caustic soda solutions of various concentrations, expressing the liquor and repeatedly washing the material with absolute alcohol. After drying in a vacuum the amount of soda retained was determined either by noting the increase in weight of the cotton, or by washing the soda out with water, evaporating with sulphuric acid, and weighing as sodium sulphate. On steeping cotton in a lye too dilute to produce Mercer's well-known effect and subsequently treating as above indicated, no increase in weight was observed, and Gladstone therefore concluded that soda was not absorbed by cotton from such weak lyes. On substituting the dilute lye by concentrated soda solution capable of producing the Mercer effect it was, however, noted that the 20 grm. lot of cotton increased in weight to 24.4 grms. and "contained an amount of soda which when dissolved out by water, neutralised by sulphuric acid and evaporated in a platinum dish gave 4.8 grms. of sulphate equal to 2.1 grms. of absolute soda."

In a number of experiments performed as just described, Gladstone found that 20 grm. lots of cotton yielded the quantities of sodium sulphate stated in the following table after treatment with lyes of different concentrations.

Experiment No.	Strength of soda solution, sp. gr.	Amount of sodium sulphate.
III.	(25° Tw.) 1.124	grms. 2.70
IV.	do. do.	2.71
V.	do. do.	2.05
VI.	do. do.	3.12
VIII.	(68.5 Tw.) 1.342	4.25
IX.	1.342	4.70
X. (weight of cotton, 12.05 grms.)	1.124	2.00
XII. (weight of cotton, 14.67 grms.)	(?)	3.15

His mode of treating the cotton after immersion in the soda differed in the various experiments. Thus, in No. III. he extracted with absolute alcohol, in No. IV. re-mercerised the cotton used in No. II., in No. V. "ordinary rectified spirits" was used for washing and in Nos. VI., VIII., and IX. hot alcohol of sp. gr. 0.825 (92.5 per cent.) was used, whilst in experiment No. XII. absolute alcohol was used for washing the cotton.

Gladstone attached special importance to experiment numbered XII., although in this case he does not state the strength of the soda used. From the results of these experiments, he concluded that "it appears that lignine is capable of forming a combination with soda, the proportion of the alkali varying with the strength of the solution employed but in no instance exceeding one atom, and that this compound is decomposed by water, being evolved into its original compounds." The formula which he gives to the soda cellulose is $C_{14}H_{20}O_{20}NaO$ which corresponds in modern nomenclature to $C_{14}H_{16}O_{18}NaOH$.

W. Vieweg (Ber., 1907, 40, 3876) determined the amount of caustic soda which "combines" with cotton during

immersion in the solution for 3 hours in the following manner. 3 grms. of cotton wool were immersed in 150 grms. of soda lye of known strength. The cotton was shaken with the solution for one hour and then allowed to remain in it for two hours. 50 c.c. of the residual soda solution were now titrated, the difference indicating the amount of soda taken up by the cotton. With a solution of caustic soda containing 16 per cent. of sodium hydroxide Vieweg obtains a value which corresponds to the formula $(C_6H_{10}O_5)_2NaOH$ and is identical with certain of the results obtained by Gladstone. He states that with solutions containing more than 35 per cent. of sodium hydroxide, the soda cellulose has approximately the composition $(C_6H_{10}O_5)_2(NaOH)_2$.

From the fact that the curve representing the amount of sodium hydroxide taken up by the cotton wool exhibits two horizontal parts, Vieweg concludes that a chemical reaction takes place during mercerisation.

The method adopted by Gladstone seems to lend itself very well for the purpose of ascertaining the amount of soda which cotton absorbs from caustic soda solutions, although on comparing the results it will be found that they differ considerably; Vieweg's titration method is, however, certainly open to objection. Considering the enormous technical importance of mercerisation at the present moment, it seemed of considerable interest to repeat and to continue Gladstone's experiments.

Unfortunately Gladstone gives comparatively few data as to the manner in which the experiments were carried out, and in one experiment only are we informed as to the kind of cotton which he has employed. No description is given as to the treatments which the cotton had undergone previous to immersion in the soda solutions, and no statement is made as to whether the experiments were carried out with one and the same quality of cotton. These are points which may exercise a considerable influence upon the results. In his experiments Vieweg uses cotton wool as employed for medical purposes; this, however, usually contains oxycellulose and is thus of doubtful uniformity. In the investigation set forth in this paper special care was therefore taken to obtain a pure and uniform material for all the experiments carried out. For this purpose a large quantity of a loosely twisted cotton yarn, made from a very fine Egyptian cotton, was boiled twice with sodium carbonate solution in a high pressure kier, thoroughly washed, and bleached with a sodium hypochlorite solution obtained by electrolysis a solution of common salt. The bleaching operation was carefully regulated so as to avoid the formation of oxycellulose, and both boiling and bleaching were performed under the customary technical conditions. The yarn was well washed and transferred to a drying stove in which it remained for seven days at a temperature of about 60° C. After this treatment the cotton contained 6.77 per cent. of moisture and 0.086 per cent. of ash. The yarn was now cut into pieces of about 2 in. in length and 150 samples, each corresponding to 10 grms. of absolutely dry cotton, were weighed out in the stove. These were then carefully wrapped up and used as required in the experiments.

A considerable number of preliminary experiments had to be carried out with a view to ascertain the method which gave the most reliable results.

Gladstone, in Experiment No. VI., states that he used hot absolute alcohol for washing, and that 20 grms. of cotton which had been immersed in caustic soda of 1.124 sp. gr. after having been freed from the soda retained mechanically, yielded 3.12 grms. of sodium sulphate. 10 grms. of the cotton were immersed for 20 hours in 200 c.c. of caustic soda solution of 51.5 Tw.; after pressing out lightly the cotton was transferred to a Soxhlet and extracted with absolute alcohol. The extraction was carried on until the alcohol syphoned from the cotton did not react with phenolphthalein. It was now treated as described by Gladstone (*loc. cit.*) and found to yield 0.043 grms. of sodium sulphate, corresponding to 0.024 grms. of sodium hydroxide.

Eight other experiments in which the cotton was immersed in solutions of various strengths gave similarly low results. Practically all the soda is extracted by hot alcohol from the cotton; it is therefore evident that the

"soda cellulose" is decomposed by hot alcohol and that no reliable results could be expected by this method. Two parallel experiments were now carried out by immersing 20 grms. of cotton as in the first experiment but washing it afterwards with absolute alcohol at ordinary temperature. The cotton containing the soda was placed in glass stoppered bottles and repeatedly shaken with absolute alcohol (about 280 c.c. of alcohol for each 10 grms. of cotton); the alcohol was frequently changed until phenolphthalein produced a very faint pink coloration when added to the alcohol. The washing of the samples occupied about 18 days. One of the washed samples was decomposed with water in the Soxhlet and the water evaporated, the residue treated with sulphuric acid in a platinum basin and the amount of sodium sulphate remaining was found to be 0.7852 grms.

The second sample was incinerated in a platinum basin, the residue repeatedly treated with sulphuric acid, and finally heated until the weight remained constant. The sample gave 0.7897 gm. of sodium sulphate. This result agreeing so well with the one found by decomposition with water, it was decided to employ this method as the more convenient one in all experiments. In carrying out the tests with phenolphthalein the following interesting observation was made. Cotton which still contains free caustic soda gives a very strong reaction with phenolphthalein, whilst cotton which had been freed from all the soda removable by washing with absolute alcohol does not react with phenolphthalein whilst immersed in the alcohol. On removing the cotton from the alcohol and exposing it to the air for a short time moisture is attracted in sufficient quantities to produce decomposition of the soda cellulose; the free alkali then reacts readily with the phenolphthalein.

Gladstone, in his Experiment No. V., used rectified spirit for the washing in place of absolute alcohol, and it seemed therefore of interest to ascertain whether the results obtained by washing with 90 per cent. alcohol would differ appreciably from those obtained when absolute alcohol was employed. For this purpose two lots of cotton (20 grms.) were treated as in the last two experiments and washed with 90 per cent. alcohol. After washing for about 18 days, the alcohol from both samples still showed a distinct alkaline reaction with phenolphthalein. One of the samples was then incinerated and found to yield 0.783 grms. of sodium sulphate; from this it is seen that the weaker alcohol gives a slightly lower result—no doubt due to a slow decomposition of the "soda cellulose." After washing the other sample for five months the alcohol still showed a distinct alkaline reaction. On incinerating this sample it was found to contain much less sodium sulphate (0.3435 gm.) than the sample which had been washed for 18 days. Washing with 90 per cent. alcohol can therefore not be expected to give satisfactory results. One very important conclusion can, however, be drawn from the two experiments, namely, that there is no danger of any interference with the results by minute quantities of water which the absolute alcohol may attract from the air during the operation of washing and during the changing of the alcohol.

Gladstone immersed the cotton one hour in the soda whilst Vieweg shook the cotton for 1 hour with the soda and allowed it to remain in contact for two hours after shaking. Vigorous shaking of the cotton whilst in contact with the soda solution is open to the objection that disintegration of the fibres is unavoidable. The authors therefore prefer immersion of the cotton for a prolonged period with occasional shaking. This has one further important advantage in that slight variations of the temperature during immersion are without appreciable influence upon the results obtained. It remained, however, to be seen whether the amount of soda absorbed by cotton varies much with the time of immersion in the soda solution, because Miller (Ber., 1907, 40, 7902) first drew attention to the fact that if cotton is immersed in soda lyes of high concentrations for a prolonged period, the amount of soda absorbed by the cotton is slightly less than when immersed for a shorter period. In order to ascertain the influence of time a number of experiments were carried out, and the following results obtained.

Strength of caustic soda solution 50° Tw. cotton.

Time of immersion.	Sodium hydroxide absorbed.
	GRMS.
30 seconds	0.269
1 hour	0.253
24 hours	0.250

It will be seen from these results that no objection can be taken to immersion of the yarn in the caustic soda solution for a prolonged period. All the results obtained during the preliminary experiments indicate very much lower absorptions than those recorded by Gladstone and by Vieweg. It became of interest to ascertain Gladstone's method of working. For this purpose it was considered advisable to use litmus as indicator in place of phenolphthalein, on the presumption that this indicator was employed by Gladstone. In the first experiment 20 grms. of cotton were immersed for 20 hours in caustic soda solution of 45° Tw. and washed with absolute alcohol for about two days or until no alkaline reaction could be detected with litmus. This sample again gave a much lower result than that obtained by Gladstone, namely, 1.02 grms. of sodium sulphate from 20 grms. of cotton, but a much higher value than those obtained in the other experiments. In a further experiment the conditions observed in one of Gladstone's experiments were exactly adhered to: 20 grms. of cotton were immersed in 600 c.c. of caustic soda lye of 1.124 sp. gr. (241° Tw. for 1 hour, slightly pressed out and very quickly washed in about 8 changes of absolute alcohol, using for every washing operation about 1 litre of alcohol; after the last washing the alcohol showed practically no alkaline reaction with litmus. The sample was then allowed to remain over night in a tightly stoppered bottle out of contact with the air. On examination of the alcohol which had run out of the cotton it was found to give a very strongly alkaline reaction. The sample of cotton was then incinerated and yielded 2.39 grms. of sodium sulphate. The average amount of sodium sulphate obtained in Gladstone's experiments was 2.35 grms. A further experiment was carried out by immersing the cotton for one hour in 600 c.c. of caustic soda solution of sp. gr. 1.342 (68° Tw.). The washing of the same with absolute alcohol was conducted similarly to the last experiment and on incinerating 4.59 grms. of sodium sulphate were obtained. By employing the same strength of caustic soda, Gladstone obtained on the average 4.475 grms. of sodium sulphate. It has thus been clearly demonstrated in what manner Gladstone obtained his values and further, that his values cannot be accepted as representing the actual amount of caustic soda which is retained by cotton in such a manner that it cannot be removed by washing with absolute alcohol. Having established by means of our preliminary experiment that cotton retains a definite amount of caustic soda which cannot be removed by washing with absolute alcohol, comparative experiments were carried out with a view to ascertain in what manner the strength of the caustic soda solution used in mercerising influences the degree of the formation of the so-called "soda cellulose."

Experiment No. 1.—All the experiments were conducted at ordinary temperature, the caustic soda solutions were prepared from pure caustic soda (99.9 per cent. NaOH) and the strengths of the solutions were ascertained both by means of the areometer and by titration. The time of immersion of the cotton in the soda lyes was 67 hours. The well stoppered bottles were shaken from time to time; the soda was poured off afterwards and each of the bottles was immediately filled with 400 c.c. of absolute alcohol, and well shaken. After two hours the alcohol was poured off and fresh alcohol added to each sample. The washing was now conducted systematically in accordance with the counter-current principle so as to reduce the amount of alcohol necessary to a minimum. Every two hours the alcohol from the sample which had been treated with caustic soda of a certain strength was transferred to the bottle containing the sample which contained the cotton treated with the next higher con-

centration of soda, whilst fresh alcohol was added to the sample treated with the lowest strength of soda. Thus the alcohol on all the samples was changed 4 to 5 times per day.

The alcohol was from time to time tested with phenolphthalein and when free from alkali it was allowed to remain in contact with the sample over night. When no alkali could be detected in the alcohol after this time the sample was removed and immediately incinerated in the manner described under the preliminary experiments. The results of these experiments expressed as sodium hydroxide are given in Table No. 1. The quantities of soda retained by 100 grms. of dry cotton are given.

Experiment No. 2.—The cotton samples were treated with the different strengths of caustic soda lye in gas wash bottles for 67 hours, in such a manner that the bottles were filled with the soda solution right to the top so as to prevent the solution from coming in contact with the air during immersion of the cotton. 10 grms. of cotton were used in each experiment and each of the bottles contained 600 c.c. of caustic soda lye. The soda lye was then pressed out of the cotton as far as possible and the bottles rapidly filled with absolute alcohol. Connections were made between all the bottles in such a manner that the absolute alcohol could be passed through continuously on the counter-current principle. The fresh alcohol entering the bottle containing the cotton which had been treated with the weakest soda lye, was then passed through all the other bottles in such a manner that it ultimately left the bottle containing the cotton which had been treated with the strongest lye. After washing in this manner continuously during seven weeks it was found that the alcohol discharged from the last bottle still reacted alkaline with phenolphthalein. The bottle containing the cotton which had been treated with soda of 80° Tw. was then disconnected and the alcohol coming from the one which contained the cotton treated with a 70° Tw. lye was also found to give a slight alkaline reaction. On disconnecting this bottle, however, the alcohol discharged from the one containing the cotton treated with the 60° Tw. lye was found on testing to be free from soda. The cotton samples were removed from the bottles and incinerated as described under Experiment No. 1. The results are given in Table No. 1.

It will be noticed that the soda has been almost entirely removed during this very thorough and continuous washing from the cottons which had been treated with soda of 1°, 5°, 10°, and 20° Tw.

The values found for the strengths above 20° Tw., although lower, if plotted in a curve clearly exhibit the same characteristics as those obtained in Experiments I. and III. This seems to prove that whilst practically all the soda can be removed by prolonged washing from cottons which have been treated with soda lyes of strengths up to and including 20° Tw., the "soda cellulose" produced by immersing cotton in lyes above 20° Tw. is much more resistant to the action of the alcohol.

It is of interest to further point out that if the amount of sodium hydroxide obtained in Experiment No. I. with the 20° lye is deducted from the amounts obtained with the higher strength lyes, the resultant figures obtained in Experiments Nos. I. and II. are practically identical. Having established in Experiment No. II. that slight decomposition of the "soda cellulose" takes place during this prolonged washing, a further series of experiments (No. III.), similar to Experiment No. I., was undertaken, in which smaller bottles, which were entirely filled with alcohol each time, were used. It had been shown by Hübner and Pope (this J., 1904, 23, pp. 404 *seq.*) that both the dyeing and the shrinkage curve of cotton yarn which had been treated with caustic soda solution rises very rapidly when soda of from between 20° and about 26° Tw. strength is used, whilst it rises more slowly from between 26° and 30° Tw. Maximum shrinkage was obtained with soda of 45° Tw. It was therefore considered of interest to ascertain whether similar results would be obtained as regards the soda absorption. In Experiment No. III. soda of 23° and 26° Tw. was therefore used in addition to the strengths

used in Experiments Nos. I. and II. The results obtained in Experiment No. III. clearly show that the authors have further substantiated the observation made by Hübner and Pope, in that the absorption of caustic soda by cotton rapidly rises if soda lye of between 23° and 26° Tw. strength is used and further that maximum absorption takes place with a lye of about 40° Tw.

From the results obtained in Experiments Nos. I. and III., it will, therefore, be seen that the amounts of sodium hydroxide absorbed by cotton from solutions of caustic soda from 30° Tw. to 80° Tw. are practically identical. Maximum absorption takes place if cotton is immersed in caustic soda solution of about 40° Tw., whilst it absorbs slightly less from stronger solutions.

As regards the exceedingly slow decomposition of the "soda cellulose" during prolonged washing with absolute alcohol, observed in Experiment No. II., attention might be drawn to the behaviour of wool fibres dyed with Naphthol Yellow S. (Hübner, J. Chem. Soc., 1907, 1057). The excess of the Naphthol Yellow can be readily removed by washing the dyed wool fibres in water. It has, however, been shown that if the fibres are repeatedly soaked in distilled water during a very long time, practically all the colouring matter may be removed.

The authors consider themselves justified, therefore, in stating that the results obtained in the experiments brought forward are to be regarded as a correct explanation of the manner in which caustic soda is absorbed by cotton fibres from solutions of different strengths, but that the results of their experiments do not support the suggestion of the existence of distinct chemical compounds or "soda celluloses," which has been advanced by Gladstone and by Vieweg.

Although Vieweg (*loc. cit.*) has attempted to verify Gladstone's results the amount of caustic soda absorbed by cotton from a solution of about 25° Tw. according to Gladstone is much lower than the amount given for the same strength by Vieweg, and further, a much higher concentration (about 68° Tw.) of soda is required according to Gladstone to obtain approximately the same absorption figures which Vieweg has obtained with soda solutions of from about 37° to 50° Tw.

In the third series of experiments the same amount of absolute alcohol was used in every washing operation, and as in the former experiments, the alcohol was always transferred from the cotton treated with the weaker lye to the one which had been immersed in the stronger one. The number of changes of alcohol required to free each of the samples from excess of caustic soda was noted and is given in the "washing curve," and in the last column in the table.

The authors do not attach any great importance to the numbers thus obtained, but it is interesting to note that whilst 33 additional changes of alcohol are required to free the cotton which has been immersed in the caustic soda solution of 30° Tw. as compared with the one which has been treated with a 20° Tw. solution, the difference in the number of changes of alcohol between cotton immersed in the 80° Tw. solution as compared with the 30° Tw. one is also 33.

Preliminary experiments have also been carried out to ascertain whether the washing with absolute alcohol of cotton which has been treated with strong solutions of caustic soda has any influence on the affinity of such cotton for the substantive colouring matters. It was found that cotton which has been treated with caustic soda solution of 50° Tw. if afterwards extracted with hot absolute alcohol in the Soxhlet apparatus, dyes practically the same depth with Benzopurpurine 4B as cotton which has not been treated. In a further experiment, cotton was treated with caustic soda solution of 50° Tw. and washed practically free from excess of soda with cold absolute alcohol. After this the cotton ("soda cellulose") was washed with water until free from soda, when it was found to dye practically the same shade as cotton which has been treated with the same strength of soda and washed free from soda with water without the preliminary washing with absolute alcohol.

This question, as also those of the dyeing of mercerised and ordinary cotton in alcoholic solutions, will be further investigated.

TABLE I.

Grms. sodium hydroxide in 100 c.c.	Degrees Twaddel.	Grms. sodium hydroxide retained by 100 grms. of cotton.			Times washed with absolute alcohol. Expt. III.

DISCUSSION.

Mr. W. H. PENNINGTON thought experience almost conclusively proved that the soda cellulose compound did not exist. He understood that the cotton was dried in a stove for 18 hours and then contained 6.7 per cent. of moisture.

Mr. R. E. CROWTHER was interested to learn that the authors' results did not corroborate Vieweg's results. He himself had spent considerable time endeavouring to corroborate those results, without success. Vieweg further stated that cotton which had been fully mercerised in the ordinary manner absorbed more caustic soda than did unmercerised cotton; he had been able to corroborate this. It seemed to be a rather suggestive fact. There might not be such changes as were at first supposed in the cellulose resulting from mercerisation, but there appeared to be some. Mercerised cotton did not behave in some of its reactions, *e.g.*, acetylation, as ordinary cotton did. Even when the mercerised cotton had gone through the process of being converted into artificial silk it was entirely different. One point mentioned was the loss of the qualities of mercerisation on washing with alcohol. He had come to the conclusion that mercerised cotton, dried with alcohol, behaved much in the same way as ordinary cotton in regard to the absorption of substantive dyes.

Dr. R. ANSPACH inquired whether the decomposition of the alkali-cellulose in the air was perhaps due to the action of carbon dioxide?

Dr. J. BURGER asked if a microscopical examination had been made of the mercerised cotton which had been treated with hot alcohol?

Mr. W. H. PENNINGTON recalled Mr. Hübner's statement that when the soda was washed out by alcohol the cotton dyed practically the same shade as untreated cotton. He wished to know whether that applied to different strengths of caustic soda lye.

Dr. B. W. GERLAND asked whether the authors had taken note of the temperature at which the caustic soda acted upon the cotton?

Mr. HÜBNER, in reply, said that the particular method of drying the cotton had been adopted in order to obtain a perfectly uniform material as regards moisture. It was well known that cotton which had been dried thoroughly at 100° C. absorbed moisture very slowly and that it was exceedingly difficult to obtain uniform absorption. In regard to the absorption of soda by cotton which had been mercerised, this method was suggested by Vieweg to distinguish mercerised from ordinary cotton. There was a distinct difference in the behaviour of mercerised cotton towards reagents as compared with ordinary cotton. Some manufacturers of artificial silk mercerised the cotton previous to dissolving it in ammoniacal cupric oxide. A number of experiments had been made in which mercerised cotton had been washed free from soda, dried, and had been then extracted in the Soxhlet apparatus with absolute alcohol and with other solvents. That which had been extracted with absolute alcohol invariably exhibited less affinity for the substantive cotton dyes than did the untreated material. These experiments were still in progress and he hoped to lay the results before the Society at a later date. Water by itself decomposed the so-called "soda cellulose," but a joint action of both water and carbon dioxide might take place. A microscopical examination of cotton which had been immersed in soda lye and afterwards washed free from soda by treatment with hot absolute alcohol had not been made. The point possessed interest and would be investigated, but he did not expect that the structure of the fibres would differ much from that of ordinary mercerised cotton which had been washed with water after immersion in the soda lye, because the typical changes, *i.e.*, the untwisting, the swelling, *etc.*, of the fibres took place during immersion in the lye. In the preliminary experiments only one strength of caustic soda had been used but that question would be fully investigated. The temperature of the caustic soda solutions was of great importance, and had been taken fully into consideration in the experiments.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—8d. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.
United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs Bourgeois, Paris (3e.).

German.—1 mark each (with full particulars) to Kaiserlich Patentamt, Berlin, Germany.

I.—PLANT, APPARATUS, AND MACHINERY.

PATENTS.

Evaporators for the concentration of liquids. J. W. Macfarlane, Cathcart, N.B. Eng. Pat. 11,088, May 22, 1908.

THE liquid enters the evaporator through the opening, *k*, passes down the first group of tubes, *c*, into the cup, *g*, at the bottom, and returns upwards through the tubes, *b*, the upper ends of which project beyond the upper tube-plate. The tubes are heated by steam introduced through *r*, and the vapour given off collects in the upper dome, *j*, and passes away through *q*. By means of cross baffle-plates the liquid is caused to pass through the various sets of tubes in succession and is finally discharged through *l*.—W. H. C.

Vacuum-pan for evaporating apparatus. G. R. Ray, Manistee, Mich. U.S. Pat. 920,997, May 11, 1909.

THE claim is for a system of vacuum-pans each provided with a steam-belt heater and having a ring pipe extending round each steam-belt and communicating therewith to convey air from the steam-belt to a "vacuum line." The first pan of the series is heated by steam from an external source of supply, and the steam-belt of each succeeding pan is connected with the vapour space of the preceding pan.—W. H. C.

Centrifugal machine. K. Krausch, Darmstadt, Germany. Eng. Pat. 16,034, July 28, 1908. Under Int. Conv., July 29, 1907.

IN centrifugal machines having a perforated drum which has the shape of a truncated cone and from which the

dried materials are discharged, without stopping the rotation, by raising the drum, the claim is for rigidly attaching the outer liquid-collecting envelope to the drum in order to facilitate the discharge of the liquid and to prevent its return to the separated solid matter. The lifting of the perforated envelope is effected by a lifting-plate supported by ball bearings on a collar on the spindle and operated by a lever.—W. H. C.

Centrifugal separator. H. D. Dibble, Mystic, S.D. U.S. Pat. 921,371, May 11, 1909.

THE claim is for a centrifugal machine the drum of which is provided with peripheral outlets for the liquid, these outlets being closed by valves, operated by levers controlled by the weight of the materials in the bowl of the machine.—W. H. C.

Temperature of heated objects; Determining the —. H. Brearley, Sheffield. Eng. Pat. 21,623, Oct. 13, 1908.

A METALLIC salt or mixture of salts having a definite melting point and used in the form of a powder or made into a paint or paste with oil, vaseline, or wax is scattered or painted upon the object the temperature of which is to be determined. If the temperature of the object is

below that at which the salt or salt mixture melts, the latter remains visible as a light-coloured streak. If on the other hand the temperature of the object is higher, the salt mixture melts and can no longer be observed.—W. H. C.

Raising water; Apparatus for —. A. A. Humphrey, London. Eng. Pat. 23,281, Oct. 31, 1908.

WATER from the tank, *a*, flows down the pipe, *b*, into the box, *d*, and draws in air through *c*. The air and water flow down *f*, the air becoming compressed, and enter the rising main, *g*, provided with a foot valve, *h*. The compressed air carries up the water on the principle of an air-lift pump into the overhead tank, *a*, from which a portion returns, as described, through *b*, to compress the air. In order to facilitate the starting of the pump, a valve, *k*, is fixed at about the normal level of the water in the well and remains open until there is a strong rush of water up the pipe, *g*.—W. H. C.

Centrifugal dryer. O. Keefer, Assignor to I. Lichtenstein, New York. U.S. Pat. 922,149, May 18, 1909.

THE materials to be dried are put into the cylindrical cage, 22, formed by the rods, 17, which connect the discs, 16, and which is provided with a door, 20, and is

mounted on a shaft, 12, rotated by the pulley, 13. The cage is covered by a movable hood, 4, and is mounted on a stand, 2, surrounded by a gutter, 3, to carry away the water.—W. H. C.

Condensing and purifying smoke. S. I. Clawson, Salt Lake City, Utah. U.S. Pat. 922,260, May 18, 1909.

The smoke gases are drawn from the flue, 2, through the pipe, 1, into the water-pump, 10, by the suction caused by water issuing from the jet, 4. The smoke gases and water pass down the zig-zag fall-tube, 11, the bottom of which terminates just above the level of the water in the tank, 7. The smoke particles are condensed and collect along with the water in the tank, 7, and the gases pass away to the chimney by the flue, 13. The water in 7, is lifted by the pump, 6, and returned to the water jet.—W. H. C.

Retort for distilling gases and vapours. P. A. Emanuel, Aiken, S.C. U.S. Pat. 922,407, May 18, 1909.

The claim is for a retort mounted on trunnions so that it can be tilted, which is connected at one end to a smoke-stack by a movable connecting piece and at the other end with a movable furnace, the whole being suitably locked together when in operation.—W. H. C.

Calcination; Process of — J. C. Heckman, Allegheny, Pa., Assignor to W. J. Gilmore, Pittsburg, Pa. U.S. Pat. 922,425, May 18, 1909.

The process claimed consists in introducing the substance to be calcined into the furnace in a liquid or diluted condition, so that the furnace is filled to a substantially equal depth at all points. The heating is arranged so that it is practically uniform and continuous over the whole area of the furnace hearth.—W. H. C.

Separating solids from liquids; Centrifugal machine for — A. J. Ericsson, Stockholm, Assignor to Aktiebolaget Separator, Stockholm. U.S. Pat. 921,814, May 18, 1909.

SEE FR. Pat. 392,702 of 1908; this J., 1909, 77.—T. F. B.

Mixtures; Apparatus for obtaining intimate — E. Dor-Delattre, Liège, Belgium. U.S. Pat. 922,863, May 25, 1909.

SEE Eng. Pat. 24,958 of 1907; this J., 1908, 492.—T. F. B.

Deposits; Device for removing — from liquor-receptacles without interrupting the work or altering the level of liquor. Usine Genevoise de Dégrossissage d'Or. Ger. Pat. 209,859, July 27, 1907.

The apparatus is shown in the accompanying figure, and the method of working is as follows:—With the valve, b_1 , open, and the valves, b_2 and b , closed, the deposit produced in the liquor-receptacle, c , collects in the chamber, f_2 . When it is desired to remove the deposit, the opening, o_1 , is closed by the valve, b_1 , and the valve, b_2 , is opened by raising the vessel, f . As the chamber, f_2 , is emptied, air enters through the hollow valve-stem, t_1 , which reaches to above the level of the liquor in c . In order now to again put the vessel, f , into communication with the receptacle, c , without altering the level of liquor in the latter, f_2 is filled with

liquid through r , which is connected with a suitable supply reservoir containing such a head of liquid that there is no difference of pressure on the two sides of the valve, b_1 , which can then be opened.—A. S.

Raising liquids; Means for — H. P. Esping, Nässjö, Sweden. U.S. Pat. 922,870, May 25, 1909.

SEE Eng. Pat. 9283 of 1908; this J., 1909, 590.—T. F. B.

II.—FUEL, GAS, AND LIGHT.

Fuels; Maximum temperatures attainable with ordinary — J. von Ehrenwerth. Metallurgie, 1909, 6, 305–315.

THE author calculates the calorific intensity, or maximum temperature theoretically attainable, of various gaseous fuels, and shows to what extent these temperatures are reduced in practice owing to dissociation of carbon dioxide and steam. Thus, the theoretical calorific intensity of water-gas is 1840°C , or, if 0.7 of the heat produced is used for the preliminary heating of gas and air, 2938° ; whilst the temperatures actually attained are only 1460° and 1940° respectively. From the figures given, it appears that where regenerative heating of gas and air is practicable, the temperatures obtained with water-gas are only slightly higher (e.g., 65°) than those obtained with carbon monoxide (producer-gas); but that without preliminary heating of gas and air, considerably higher (e.g., at least 120°) temperatures can be obtained by using water-gas instead of producer-gas.—A. G. L.

PATENTS.

Anthracite briquettes; Producing — J. F. Lovejoy, Assignor to A. Stein, New York. U.S. Pat. 921,550, May 11, 1909.

THE coal is first heated to between 250° and 350°F . and then mixed at about 240°F . with molten pitch having a melting point of about 160°F . and heated to 240°F . The mixture is thoroughly agitated and then briquetted at a temperature of from 160° to 220°F .—W. H. C.

Coke oven. C. Schroeter, Assignor to J. F. Hill, Chicago, Ill. U.S. Pat. 922,201, May 18, 1909.

THE oven comprises a battery of horizontal retorts, with a combustion chamber beneath the sole of each retort. The space beneath the sole of each retort is divided by a horizontal partition into a combustion chamber and an air chamber beneath it. Vertical burner

pipes, connected to horizontal fuel pipes running along the length of the air chambers, project concentrically through apertures in the partitions so that air is drawn in with the fuel into the combustion chambers. The fuel pipes and air chambers are connected to mains running along the front of the oven, and branch pipes are provided for air and fuel for heating the side walls of the last retort at each end of the oven. The heating gases from the combustion chambers pass around the retorts through chambers filled with chequer-brickwork, and finally pass through downtake flues between the retorts to main flues running transversely beneath the oven.—A. T. L.

Retorts; Vertical —. R. M. Brooke, Halifax, and R. Dempster and Sons, Ltd., Elland, Yorks. Eng. Pat. 16,405, Aug. 4, 1908.

THE principle of the invention described in Eng. Pat. 14,637 of 1906 (this J., 1907, 859) is applied to the heating of vertical retorts. The retorts are arranged in a setting divided into compartments by horizontal partitions, and a separate combustion chamber and regenerator are provided in connection with each compartment. The supplies of secondary air and of producer gas to each combustion chamber, and the exit from each regenerator can be separately controlled. One combustion chamber may communicate with several of the horizontal compartments.—A. T. L.

Gas-furnace; Regenerative —. J. B. Acker, New York. U.S. Pat. 921,322, May 11, 1909.

THE claim is for the provision of a single-furnace chamber beneath each bench of "through" retorts. The furnace has a charging opening in one end wall of the bench and a stoking opening in the opposite end wall. The walls of the furnace slope downwards from the above-mentioned openings to a grate which is provided with a slinking door.—W. H. C.

Air-gas producing plants. J. Holroyd, Gringley-on-the-Hill, Notts. Eng. Pat. 14,110, July 3, 1908.

AIR is blown by a fan, driven by a gas-engine operated by a portion of the air-gas produced, into a carburetting chamber. Within the latter is a vane-wheel having its vanes covered with cotton and having wicks of cotton hanging down from the tips of the vanes. The carburetting liquid is supplied from a store tank by wicks which project into the carburetting chamber and from which the liquid drips on to the vane-wheel. Any excess of liquid drains into a pan beneath the wheel and is again brought into action by the wicks attached to the tips of the vanes.—W. H. C.

Gas; Process of manufacturing —. W. H. Cone, Assignor to the Coal Products and Power Co., Detroit, Mich. U.S. Pat. 922,857, May 25, 1909.

THE process is carried out in a pair of producers. Each producer is provided with a central blast-pipe at its lower end, and with an outlet pipe at the upper end leading into the other producer at about the middle of the height of the fuel column. The blast is admitted to each producer in turn, and the producer-gas formed in one producer passes to the centre of the fuel column of the other producer, and then downwards through the lower part of the fuel column to the blast-pipe, which is now connected by a three-way valve to the gas main. At the same time the raw fuel which forms the upper part of the fuel column is coked, the distillation gases passing downwards with the producer-gas. Subsequently the hot gas from the first producer is passed through this coked fuel to bring it to incandescence, and the currents are then reversed.—A. T. L.

Gas producer, especially for moist combustible materials. J. Pintsch Akt.-Ges. Ger. Pat. 209,387, Aug. 21, 1908

THE invention relates to gas-producers provided with a re-grate both at the top and the bottom, the producer-chamber being surmounted by another chamber in which the moist combustible material is subjected to a preliminary drying operation. The steam and waste

gases pass from the drying chamber to a chimney. According to the present patent, the supply pipe for the gas (e.g., the exhaust gas from the gas-engine) used as drying agent, is provided with a branch which ascends and then leads into the chimney, where it ends in a jet and thus acts as an exhauster, improving the chimney draught.—A. S.

Electric incandescent lamps; Production of tungsten filaments for —. Westinghouse Metal Filament Lamp Co., Ltd., London. From The Westinghouse Metallfaden Glühlampen Fabr., Ges.m.b.H., Vienna. Eng. Pat. 14,942, July 14, 1908.

METALLIC tungsten is prepared by Delépine's method, tungsten trioxide being reduced with zinc dust at red heat, and the resulting product treated with acid to remove the zinc oxide and excess of zinc, leaving the metal behind as a fine mud. After thoroughly washing with water by decantation, the mud is concentrated by evaporation until it acquires a consistency suitable for insertion in a press cylinder, from which the filaments are subsequently squirted. The raw filaments, after being heated to 800 C. for half an hour, in the absence of air, are finished in the usual manner, being raised to white heat, in an atmosphere of hydrogen and nitrogen, by the passage of an electric current.—W. E. F. P.

Electric incandescent filaments; Manufacture of — from tungsten or other difficultly fusible metal. Siemens und Halske Akt.-Ges., Berlin. Eng. Pat. 25,854, Nov. 30, 1908. Under Int. Conv., Dec. 11, 1907.

THE powder of the difficultly fusible metal is coated, galvanically or chemically, with 10 to 20 per cent. of a very ductile metal (such as gold, nickel, or silver) in such a manner as not to destroy the pulverulent character of the product. The coated metallic powder is then worked up by pressing or rolling, without fusion, into a filament from which the added metal is subsequently expelled in a vacuum by the passage of an electric current; or the coated metallic powder may be stamped into a tube of very ductile metal which is then drawn or rolled to the desired form, the encasing metal being afterwards removed by any of the usual methods.—W. E. F. P.

Electric incandescence filaments; Manufacture of — from tungsten and other difficultly ductile metals. Siemens und Halske Akt.-Ges., Berlin. Eng. Pat. 2853, Feb. 5, 1909. Under Int. Conv., Feb. 11, 1908. Addition to Eng. Pat. 4814 of 1907.

IN the process described in Eng. Pat. 4814 of 1907 (this J., 1907, 519), tungsten powder is charged into a tube of ductile metal, such as steel, which is then rolled or drawn into the form of a filament. The improvement consists in inserting a tube of copper or other very ductile metal into the steel tube before the addition of the tungsten powder. When filled, the tube is closed by a screwed or wedged copper stopper, and is then rolled or drawn to a wire of the desired thickness, the external steel covering of which is subsequently removed by means of dilute acid, leaving the tungsten encased in a thin shell of copper. The finished filament is obtained by electrically heating the wire, in a vacuum or suitable rarefied atmosphere, in such a manner as to cause the copper shell to vaporise; or the wire may be so heated as to cause the shell to alloy with the tungsten, thus permitting of a further rolling or drawing process before the final vaporisation of the copper.—W. E. F. P.

Incandescent electric lamp filaments; Manufacture of —, and apparatus therefor. The British Thomson-Houston Co., Ltd., London. From Gen. Electric Co., Schenectady, U.S.A. Eng. Pat. 3951, Feb. 17, 1909.

THE difficulties usually experienced by reason of the sticky nature of the raw filament are obviated by causing the extruded thread to pass over a heated shoot in the special apparatus described.—W. E. F. P.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Petroleum oils: Optical activity of certain crude —. M. Rakusin, Ber., 1909, 42, 1640—1647.

OBSERVATIONS made by Engler (this J., 1908, 932), Jones and Wootton (this J., 1907, 919) and others, have confirmed the author's conclusions that most natural petroleum oils yield dextro-rotatory distillates (this J., 1904, 816; 1907, 678; 1908, 397). Many oils have been found to be polarimetrically inactive, or only slightly dextro-rotatory, whilst an oil from Java examined by Engler (*loc. cit.*) and an oil from Bornco examined by Jones and Wootton (*loc. cit.*) yielded, on distillation, fractions which were slightly laevo-rotatory. With regard to the question of the optical activity of oils yielding optically active distillates, it is pointed out that Zložiecky and Klarfeld (this J., 1908, 16) found a Galician oil to have only a slight dextro-rotation, whilst Marcusson found that an opaque oil from which the dark colouring matter had been mechanically removed was transparent to polarised light. In the author's experiments on treating petroleum oils with fuller's earth, it was found that those of the deepest colour (*i.e.*, the geologically oldest) were thus rendered transparent in polarised light. An opaque sample of Bibi-Eibat oil with a sp. gr. of 0.8800 at 15° C. yielded, after treatment with fuller's earth, a colourless filtrate with an optical rotation of -1.5° (saccharimeter degrees) in a 200 mm. tube. In like manner, an almost black Binagady oil (sp. gr. 0.9270) gave a light yellow product with sp. gr. 0.8573 and optical rotation of -2.3° . In the distillation of crude oil the optical rotation of the distillates increases with their sp. gr., and the author therefore considers that crude oils with a high degree of optical activity are probably derived from zones nearest to those of the parent oil, and that in the latter is possibly to be sought the origin of the optically-active constituents. In the case of the two polarimetrically transparent petroleum oils mentioned above, the optical activity increased during a fractional distillation from $+1.5^\circ$ to $+4^\circ$ and from $+2.3^\circ$ to $+5.8^\circ$ respectively. Contrary to expectation there was not only no racemisation in the distilled fractions, but also none in the residues. The optical activity is thus, as it were, concentrated in

the residue. Alterations in the direction of the rotation (*Drehungsinne*) such as take place in the distillation of cholesterol do not occur in the distillation of petroleum oils. In the author's opinion the optical activity of petroleum oils is to be attributed, not to the influence of terrestrial magnetism, but, as Walden also assumes, to the asymmetrical constitution of the hydrocarbon molecule in the oils.—C. A. M.

Petroleum distillates: Cause of the lubricating capacity of —. K. W. Charitschkoff. Chem. Rev. Fett-u. Harz-Ind., 1909, 16, 132—133.

THE fact that the increase in the b. pt. of the fractions obtained in the distillation of petroleum is accompanied by an increase in their mean molecular weight and iodine values, points to an increase in the proportion of unsaturated hydrocarbons and a decrease in the proportion of saturated paraffins and naphthenes. On these differences is based the method of Nastukoff, which consists in determining the amount of precipitate yielded by the oil on treatment with formalin and sulphuric acid. Gerr also attempted to separate the naphthenes and unsaturated hydrocarbons by the same method, but only succeeded in separating 8 to 10 per cent. of the naphthenes of high b. pt. from the lubricating oil mixture. In the latest methods of concentration in the lubricating oil manufacture (viscosines), there is a preliminary treatment of the oil with sulphuric acid and caustic soda. It has been found, however, in practice that vigorous treatment with acids, and especially with fuming acids (as used by Gerr), impairs the quality of mineral lubricating oils, and renders them more fluid. Whether this is also the case with the highest fractions is uncertain. The suitability of a petroleum oil for the manufacture of lubricating oils depends not only on the behaviour of its unsaturated hydrocarbons, but also on its naphthenes of high b. pt., which are not oxidised and not affected by superheated steam. Until recently it was commonly accepted by manufacturers that the only Caucasian petroleum oil suitable for the production of lubricating oil was that from Balachani. There are, however, many other Russian oils (*e.g.*, those from Bibi-Eibat and Grozni) which yield good lubricating oils when distilled with steam *in vacuo*, although the products have different physical characteristics. For example from a Grozni oil the following fractions were obtained by distillation with superheated steam in a vacuum of $\frac{1}{2}$ atmosphere.

Temperature of steam.	Temperature of fraction.	Yield.	Sp. gr.	Flashing points (Martens).	Viscosity (Engler).
°C.	°C.	Per cent.		°C.	
200	175	20	0.862	118	{ very fluid.
250	175—200	8	0.843	159	{
280	200—225	10.7	0.901	180	3' 2"
320	225—280	26.8	0.921	188	8' 12"

Residue (asphaltum) 32 per cent.; loss 2.5 per cent.

The last fraction was an excellent lubricating oil, which differed from the corresponding fraction from Baku oil in having a high sp. gr. and b. pt. Both of these qualities would be of importance in an oil for lubricating machinery used with steam under high pressure.—C. A. M.

Paraffin wax and ceresin: Quantitative separation of —. J. Marcusson and H. Schueler. Pharm. Zentralh., 1909, 50, 346.

THREE grms. of the material, free from rosin, are dissolved with gentle heat, under a reflux condenser, in 30 c.c. of carbon bisulphide. The solution is cooled to 25° C. and treated with 300 c.c. of a mixture of equal volumes of 96 per cent. alcohol and ether, also at 25° C. The precipitate is collected on a Büchner filter, washed with 25 c.c. of alcohol-ether, transferred to a tared capsule by means of warm benzene, and weighed after evaporating the solvent. The weight of the residue being *a*, the percentage of paraffin wax = $\frac{1}{3}$ (60—*a*). A ceresin which gives less than 50 per cent. of residue under this test, is adulterated; when the residue exceeds 55 per cent. the

specimen is pure. If the amount of residue is between 50 and 55 per cent., the crystalline structure of the portion remaining in the mother liquor, and its refractive power at 90° C. must be determined.—J. O. B.

Acetone reaction. Bardach. See XX.

Petroleum industry of Mexico. Board of Trade J., June 10, 1909. [T.R.]

OIL-PRODUCING lands have been discovered in the State of Vera Cruz, near the Isthmus of Tehuantepec, and the flow of oil in the wells has been of such quantity and quality that a British company have erected a large refining plant at Minatitlan, which is now in partial operation. A certain part of the production is to be fuel oil, and as the same company also work the Tehuantepec National Railway jointly with the Mexican Government, the latter's engines will be supplied with this fuel oil. Large storage tanks have been erected at Vera Cruz and other places to supply the several railways in this part of the country. When this plant is in operation it is expected that the Mexican market for foreign petroleum will disappear.

Great activity continues in prospecting for and developing oil lands, and options have been obtained on extensive tracts of land in the States of Tamaulipas, Vera Cruz, and Chiapas, and the necessary drilling plants have been brought from abroad. Test borings are being made in every direction, and reports of new wells are of frequent occurrence.

The oil well at Dos Bocas, in the northern part of the State of Vera Cruz, is remarkable for the tremendous force of the flow and the enormous output. Since the extinguishing of the fire the paramount problem has been to control the flow and save the oil. Immense earthen reservoirs and dikes have been built, but the oil has overflowed these and spread over the lagoons for a distance of several miles. The well is now under control.

One of the effects of this development in the oil districts of Mexico has been that petroleum has come into use as a substitute for coal as fuel. Formerly the Mexican railways consumed from 120,000 to 140,000 tons of patent fuel drawn from Cardiff and district, but during the latter half of 1908 they converted 50 per cent. of their engines to oil-burners, and so satisfactory and economical has the result been that it is only a matter of the erection of the necessary storage tanks for the use of coal as fuel to be given up altogether. Many industrial enterprises which were formerly coal consumers have changed, and still others are now changing, their boilers in order to use oil. This has affected the importation of coal and patent fuel to the extent of causing a decrease in imports of about 10 per cent. during 1908.

PATENTS.

Fluorene; Process for obtaining — from materials containing it. Ges. für Teerverwertung. Ger. Pat. 209,432, Oct. 13, 1908. Addition to Ger. Pat. 203,312, Feb. 11, 1908.

In preparing the sodium compound of fluorene for the purpose of separating the latter from mixtures containing it, as described in the main patent (see this J., 1908, 99), it is found that the action of sodium on the fluorene is greatly accelerated by the addition of organic bases such as aniline, benzyllamine, or pyridine or its homologues. —A. S.

Sodium compound of indene; Process for preparing a —. Ges. f. Teerverwerthung. Ger. Pat. 209,694, Oct. 13, 1908. Addition to Ger. Pat. 205,465, Feb. 12, 1908 (this J., 1909, 84).

THE sodium derivative of indene can be obtained by the action of metallic sodium on indene or mixtures containing indene at temperatures above 130° C., or in presence of organic bases (e.g., pyridine) at temperatures above 90° C.—T. F. B.

Petroleum; Method and apparatus for distilling crude —. F. Seidenschneur, Charlottenburg, Germany. Eng. Pat. 10,892, May 19, 1908. Under Int. Conv., Aug. 19, 1907.

THE crude petroleum is suddenly vaporised by treating it with superheated steam in a vessel in which a high vacuum is maintained, as described in Ger. Pat. 169,952 (this J., 1907, 87). To avoid the formation of coke and to reduce the loss in distillation, the process is carried out in large shallow vessels or stills in the following manner. The still, which is connected to a vacuum pump, is heated to 100° C. and about 200 kilos. of crude petroleum at the same temperature are run in. Superheated steam at 450° to 500° C. is constantly passed through the still and the temperature is raised to 380° to 400° C. Crude petroleum is then admitted in a continuous stream while the temperature is kept within these limits, until the amount of oil reaches 200 kilos. per sq. metre of the area of the still. The supply of oil is then stopped, and the supply of steam is increased so as to raise the temperature of the still to 420° or 430° C. The quantity of steam used is at least 30 to 40 per cent. of the quantity of oil, and the process is stopped when from 5 to 10 per cent. of the volatile material remains in the still. The steam and oil admission pipes are branched in the still so as to admit steam and oil at several points, and the steam outlets are directed obliquely downwards in front of the oil outlets, so as to direct the oil against the bottom of the still.—A. T. L.

Oil-testing apparatus. Ger. Pat. 209,399. See XXIII.

IV.—COLOURING MATTERS AND DYESTUFFS.

Dyestuffs of the thionaphthene series. P. Friedlaender. Monatsh. Chem., 1909, 30, 347—354.

THE author finds that 3-oxythionaphthene,

behaves in a similar manner to α -naphthol in that it combines with diazonium compounds to form azo-dyestuffs, and, unlike α -naphthol but similarly to indoxyl, condenses with aromatic aldehydes with the production of compounds resembling Baeyer's "indogenides" but containing a sulphur atom in place of the imino-group. The new compounds are therefore termed "thioindogenides." The benzaldehyde compound,

prepared by heating sodium oxythionaphthene-carboxylate with five times its quantity of glacial acetic acid until carbon dioxide is no longer evolved and then warming for a few minutes with a little more than the theoretical amount of benzaldehyde and a few drops of concentrated hydrochloric acid, separates in yellow needles, m.p. 127° C. Similar condensation products are obtained from derivatives of benzaldehyde. Protocatechuic aldehyde yields brownish, orange-yellow needles, m.p. above 280° C., which dye cotton mordanted with alumina dull orange; with iron oxide, coffee-brown; with chromium oxide, brownish-violet; and with tin oxide, bright orange red.

Benzeneazo-3-oxythionaphthene,

prepared in the usual manner from benzenediazonium chloride and oxythionaphthene (carboxylic acid) forms orange-yellow needles melting at 191—192° C. The compound prepared by the use of diazotised *p*-nitraniline forms orange-red needles.—J. C. C.

Lignones; Friedländer's "colour-nomenclature" of —. C. Liebermann. Ber., 1909, 42, 1851—1852.

REFERRING to Bezdzik and Friedländer's recent suggestion (this J., 1909, 468) that the name "lignone" should be used to designate the binuclear *p*-quinones, the author points out that he has already described a number of dyestuffs of the general formula,

(which is now considered more correctly to represent their constitution than that formerly adopted) as "Lignone blues" and this serves to provide relatively simple names for their derivatives. Friedländer's name for "Lignone Blue" would thus be "bis-3:5-methoxyphenylamino-benzolignone" which is much more complicated but, in view of future developments, may be found to be more suitable. Such "lignone" dyestuffs have, however, been known for a long time.—J. C. C.

Preparing benzene sulphochloride. Pummerer. See XX.

PATENTS.

Sulphide colours [dyestuffs]; Manufacture of —. R. B. Ransford, London. From L. Cassella and Co., Frankfurt, Germany. Eng. Pat. 17,352, Aug. 18, 1908.

By treatment of the sulphide dyestuffs derived from indophenols or leucoindophenols with halogen, substitution sometimes accompanied by oxidation takes place and the resulting dyestuffs are distinguished by their fastness to washing, light, and chlorine. The dyestuff to be treated is dissolved in concentrated formic or acetic acid, alcohol, carbon tetrachloride, water, or other suitable solvent and the halogen introduced into the solution; the reaction is controlled by cooling the mixture during the operation.—F. M.

Sulphide dyestuff; Process for preparing a clear red-brown —. L. Cassella and Co. Ger. Pat. 208,109, March 14, 1907.

A DYESTUFF which gives clear, fast, reddish-brown shades, is obtained by melting aminohydroxytolylphenazine (produced by the simultaneous oxidation of *p*-aminophenol and *m*-tolylenediamine) with alkali polysulphides.

—T. F. B.

Azo dyestuff and process of making same. J. and E. Fussenegger, Ludwigshafen, and L. Blangey, Mannheim, Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen, Germany. U.S. Pat. 921,516, May 11, 1909.

CLAIM is made for azo-dyestuffs prepared by diazotising 4:5-disubstituted *o*-nitranilines with β -naphthol. The dyestuff obtained by diazotising 4:5-dichlor-2-nitraniline and combining with β -naphthol is orange-red and is insoluble in water or dilute acids or alkalis.—J. C. C.

Nitrogenous condensation products from aromatic hydroxy- or amino-compounds and aromatic hydrazines; Process for the preparation of —. H. Bucherer and F. Seyde. Ger. Pat. 208,960, Aug. 28, 1906.

CONDENSATION products of aromatic hydrazines with such aromatic hydroxy- or amino-compounds as are capable of forming sulphurous esters, are obtained by the interaction of the components in aqueous solution in presence of a sulphite or sulphurous acid, or by the action of the sulphurous esters of the hydroxy- or amino-compounds on aromatic hydrazines. In many cases the primary condensation product, probably the *N*-sulphonic acid of a hydrazo-compound, undergoes transformation to the corresponding carbazole-*N*-sulphonic acid, from which by heating with mineral acids the carbazole can be obtained. By applying the reaction to various dyestuffs, other dyestuffs of different properties can be obtained. Several examples are given. (See also this J., 1908, 1014).

—A. S.

Anthracene series; Process for preparing a brown red dyestuff of the —. Farbwerke vorm. Meister, Lucius and Brünning. Ger. Pat. 208,969, March 31, 1908.

A BROWN vat dyestuff is obtained by melting with alkali dianthraquinonyl-1:4-diaminoanthraquinone; this again is obtained by heating 1 mol. of 1:4-diaminoanthraquinone or its leuco-derivative with 2 mols. of 2-bromoanthraquinone in presence of cupric acetate.—T. F. B.

Dyestuffs of the anthracene series; Process for preparing blue —. Farbwerke vorm. Meister, Lucius, und Brünning. Ger. Pat. 209,321, April 30, 1908.

SUBSTANCES which dye wool fast blue shades from acid baths are obtained by the sulphonation of symmetrical 1:4-dialkylaminoanthraquinones in presence of boric acid. Two parts of the anthraquinone derivative are heated with 60 parts of fuming sulphuric acid (20 per cent. anhydride) and one part of boric acid, for 4 to 5 hours at 120° C., the mass is poured into water, caustic soda is added, and the dyestuff is salted out.—T. F. B.

Triphenylmethane dyestuffs; Process for preparing red-violet, acid, chrome —. Anilinfarben- und Extrakt-Fabr. vorm. J. R. Geigy. Ger. Pat. 209,535, July 14, 1908. Addition to Ger. Pat. 189,938, Sept. 29, 1906.

THE aldehydes used in the principal patent (see Fr. Pat. 384,979 of 1907; this J., 1908, 497) in conjunction with *o*-hydroxycarboxylic acids for the production of triphenylmethane dyestuffs, may be replaced by the following aldehydes:—*p*-Dimethylaminobenzaldehyde, *p*-diethylaminobenzaldehyde, *p*-methylamino-*m*-tolylaldehyde, *p*-ethylamino-*m*-tolylaldehyde. The dyestuffs give deep red or Bordeaux-red shades from acid baths, changing to red-violet on chroming.—T. F. B.

Azine dyestuffs; Process for preparing —. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 209,536, May 8, 1908.

By treating with acids the azo dyestuffs obtained from diazobenzenesulphonic acid and 2-arylamino-5-naphthol-7-sulphonic acids, azine dyestuffs are obtained which dye wool and silk yellow shades, very sensitive to alkalis; it is found, however, that if these azine dyestuffs are alkylated, the products dye wool and silk clear greenish-yellow shades, very fast to alkalis.—T. F. B.

Anthraquinone derivatives containing nitrogen; Process for preparing —. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 210,019, May 1, 1908.

By the condensation of two mols. of aminoanthraquinones or their derivatives with one mol. of succinic acid, new derivatives are obtained which can be used either as dyestuffs or for the preparation of dyestuffs.—T. F. B.

Nitro-1:8-naphthsultamsulphonic acid and 2:4-dinitro-1:8-naphthsultam; Process for preparing —. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 210,222, July 5, 1907.

By treating 1:8-naphthsultam-2:4-disulphonic acid or its salts with nitric acid, one or both of the sulphonic acid groups can be replaced by nitro groups without fission of the naphthsultam ring, nitronaphthsultam-sulphonic acid and dinitronaphthsultam being produced. The products dye wool clear yellow shades, and form lakes which are suitable for colouring paper, etc.—T. F. B.

Sulphide dyestuffs soluble in water; Process for preparing —. Act.-Ges. f. Anilinfabr. Ger. Pat. 209,850, Feb. 11, 1908.

WHEN solutions of sulphide dyestuffs in sodium sulphite solution are treated with oxidising agents, such as hydrogen peroxide, sodium hypochlorite, or ammonium persulphate, the dyestuff is not precipitated, but the solution changes and becomes much deeper in colour, and does not dye cotton or wool. By evaporating to dryness, products are obtained which dissolve readily in water, the dilute solutions not being precipitated by acids in the cold. The new products are especially suitable for dyeing

leather; their solutions are precipitated by salts of copper, lead, barium, aluminium, etc., the lakes obtained being suitable for colouring paper, etc.—T. F. B.

Isatin derivative containing sulphur; Process for preparing a —. Ges. f. Chem. Ind. in Basel, Ger. Pat. 210,343, Aug. 29, 1908.

A NEW, stable thioisatin is obtained by heating indoxyl with sodium tetrasulphide in alcoholic solution, until a sample of the product, when dissolved in water, gives no precipitate of indigo when treated with air. The alcohol is now distilled off, the residue dissolved in water, and the thioisatin precipitated by addition of hydrochloric acid. It is readily soluble in alkalis, and decomposes without melting above 300° C. When condensed with 3-oxy-(1)-thionaphthene-2-carboxylic acid in xylene solution, it furnishes a bluish-red vat dyestuff.—T. F. B.

Anthracene group; Manufacture of new derivatives belonging to the —. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer and Co., Elberfeld, Germany. Eng. Pat. 10,387, May 13, 1908.

SEE Fr. Pat. 390,157 of 1908; this J., 1908, 1014.—T. F. B.

Azo dyestuffs and intermediate products for use therein; Manufacture of —. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer and Co., Elberfeld, Germany. Eng. Pat. 11,866, June 1, 1908.

SEE Fr. Pat. 391,456 of 1908; this J., 1908, 1148.—T. F. B.

Anthracene derivatives; Manufacture of —. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer and Co., Elberfeld, Germany. Eng. Pat. 18,107, Aug. 28, 1908. Addition to Eng. Pat. 28,765, Dec. 17, 1906.

SEE Addition of Aug. 27, 1908, to Fr. Pat. 372,676 of 1906; this J., 1909, 133.—T. F. B.

Sulphurised [sulphide] dyestuffs; Manufacture of —. A. G. Bloxam, London. From Act.-Ges. f. Anilinfabr., Berlin. Eng. Pat. 20,802, Oct. 2, 1908.

SEE Fr. Pat. 394,832 of 1908; this J., 1909, 305.—T. F. B.

Sulphurised [sulphide] dyestuffs soluble in water; Manufacture of —. Act.-Ges. f. Anilinfabr., Berlin. Eng. Pat. 2290, Jan. 30, 1909. Under Int. Conv., Feb. 10, 1908.

SEE Ger. Pat. 209,850 of 1908; preceding.—T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Fibres from India. Bull. Imp. Inst., 1909, 7, S—14.

(1). *Agave rigida* fibre from Madras. From six-year-old leaves, well-prepared, of good lustre, colour nearly white to pale buff, strength good, staple 3 ft. long. The product was valued at £36 to £38 per ton (Mexican "Sisal" at £34). (2). *Agave Americana* fibre from Madras. From six-year-old leaves, uneven in quality, varying from nearly white and lustrous, to gummy, poor in lustre

and contaminated with greenish pulp. Staple rather short for rope-making. Valued at £27 to £28 per ton. (3). *Furcraea sp.* fibre from Madras. From six-year-old leaves, colour buff to nearly white, fair lustre but a little gummy and stiff. Uneven strength, staple 2 to 3 feet long, therefore poor for rope-making. Valued at £26 to £27 per ton (Mauritius hemp at £24 to £30). (4). *Manila hemp* from Kullar, Madras. Well prepared, pale buff in colour, fair lustre, not so harsh as ordinary Manila hemp, rather resembling plantain or banana fibre. Average length of fibre 4 ft. 3 in. Strength poor compared with ordinary Manila hemp. Valued at £23 to £24 per ton (October, 1908). Well adapted for binder twine manufacture. (5). *Agave* fibre from Assam. Of promising quality but not well cleaned. Colour uneven, fairly lustrous, very good strength, length four feet, but some fibres shorter. Valued at £30 per ton if well cleaned. (6). *Agave sisalana* fibre from Andaman Islands (Port Blair). Buff coloured, well-cleaned, fair lustre, good strength, average length four feet. Contained less cellulose and lost more on hydrolysis and acid purification than E. African sisal hemp. This was probably due to the fibre having been washed in sea-water, since the ash contained 2.9 per cent. of sodium chloride. If this salt were absent, the fibre would be slightly superior to E. African sisal. The sample was valued at about £24 per ton (Mexican "Sisal" at about £25). (7). *Urena* fibre from Nettigandi. Somewhat harsh, greyish fibre, gummy and in parts woody, strength fair but uneven. Fibre insufficiently retted. Resembled "Aramina" fibre from Brazil, and, like it, was decidedly harsher than jute (Bull. Imp. Inst., 1903, 1, 24). Suitable for spinning and mixing with jute. The length of fibre was irregular, varying from 6 ft. to 4 ft. or less. Valued at £12 10s. to £13 (with "medium" jute at £15 to £17 per ton). (8). *Kapok* (seed-floss of *Eriodendron anfractuosum*) from South Arcot District of Madras Presidency, where it is available at 1-9d. to 4-16d. per lb. The sample was clean, but contained a quantity of seeds and occasional fragments of the capsules. Colour light brown, but slightly darker than Javan kapok, very lustrous, resilient, soft and silky. Fibres of poor strength, and 0.7 to 1.0 inch in length, with diameter varying from 0.0006 to 0.0013 inch. Brokers consider it equal to good Javan kapok, and worth about 4½d. per lb. containing seed, but 6d. if fairly free from seed. Care should therefore be taken to remove the seed as completely as possible before shipping.

Table of results of chemical examination:

Silica with Methylene Blue; The combination of —. L. Pelet-Jolivet and N. Andersen. Bull. Soc. Chim., 1909, 5, 540—546.

THE authors have further investigated the blue compound which is formed when hydrated silica is mixed with Methylene Blue (see this J., 1907, 920) and find that the composition of the compound is variable, depending on the concentration of one or other of the constituents and also on the presence of other substances. The difficulty with which the Methylene Blue is extracted from the silica indicates that the dye does not simply adhere to the silica but that there is actual combination.—W. P. S.

Lead chromate; Colouring properties of —. L. Vignon. Compt. rend., 1909, 148, 1329—1331.

TEXTILES may be dyed with lead chromate by immersion first in a solution of a lead salt and subsequently in a solution of a soluble chromate. The lead chromate is precipitated on the fibre which retains a certain quantity

after repeated washing. Textiles can also be dyed by immersion in suspensions of precipitated lead chromate in water; it is remarkable that under these conditions, silk, wool and cotton all behave alike. A good deal of the colour is removed by washing so that to obtain a given shade it is necessary to employ a great deal more colouring matter than when using a soluble dyestuff. Suspensions in liquids other than water do not give the same intensity of colour. The lead chromate is not chemically fixed to the textile but its retention is probably due to adsorption phenomena. The suspension of lead chromate is comparable to some colloidal solutions.—E. F. A.

Yarns and fabrics: Treatment of — by the Agostini process. M. Prudhomme. Bull. Soc. d'Encour., March, 1909.

THESE processes depend upon a chemical reaction which takes place upon the fibre and results in the formation of an insoluble, highly adhesive soap which becomes incorporated with the fibre itself. According to Fr. Pat. 361,772 of 1905 (this J., 1906, 1160), the material to be treated is impregnated with a mixture containing fatty acids, fats or hydrocarbons, and a metallic oxide, the proportions being so calculated that on drying the material, the metallic oxide is converted into an insoluble soap. The author has examined fabrics which have been industrially treated in this manner and finds that they remain supple, acquire a "cloth" handle, and yet are permeable by air and water. The finish is not removed by water or by soaping though in the latter case the lustre is impaired. The processes are applicable to woollen as well as to cotton goods and to the sizing of warps. Tables are given showing the increase in strength and weight of materials after being submitted to the Agostini treatment.—P. F. C.

PATENTS.

Bleaching; Method and apparatus for — and treating cloth, warps, etc. A. J. Boulton, London. From E. D. Jefferson, Lowell, Mass., U.S.A. Eng. Pat. 10,289, May 12, 1908.

FULL details are given of the construction and method of operation of a closed kier, in which cloth, warps, etc., may be bowked and fully bleached without being removed between the several operations. In connection with the kier is a trap and a ball-valve arrangement, by means of which a motive valve is intermittingly and automatically opened and closed, and whereby steam is admitted and the liquors (which have passed from the bottom of the kier into the trap) are "vomited" over the goods in the kier. Water, bleach liquors, and acid may be run into the kier by a suitable arrangement of pipes and valves. Circulation is effected by compressed air, automatically admitted and shut off as in the case of the steam during the boiling operation.—F. M.

Dyeing, washing or bleaching yarns and slubbing; Machinery for —. Brintons, Ltd., and C. Osborn, Kidderminster. Eng. Pat. 4586, Feb. 29, 1908.

THE hanks or skeins are carried on poles supported in one or more cages, the axes of the latter engaging in suitable guides for up and down movement. The cages are raised by lifting bars, provided with cranked and hooked lower ends with racks, the latter engaging during the up movement with pinions on the axes of the cages, thus turning the latter, but during the down movement of the lifting bars the cages fall by gravity. Two sets of cages may be operated by lifting arms from the ends of levers on the opposite sides of a rocking shaft, the latter being actuated by a suitable eccentric, or the rocking motion may be obtained by the employment of a steam or hydraulic cylinder, a rack engaging with a rocking toothed quadrant, being fixed to the piston rod of the cylinder.—B. N.

Dyeing and the like purposes; Centrifugal drum apparatus for —. G. Wörner, Calw, Germany. Eng. Pat. 12,913, June 16, 1908.

THE apparatus may serve as a dyeing machine or as a hydroextractor. The material to be treated is filled into

the cage, which is supported upon the vertical shaft by cones which are attached to the latter. The shaft is driven from below and passes through the bottom of the outer vessel; it may be raised or lowered in its bearings, and firmly fixed to it is a cone, which when the machine is used as a dyeing machine, closes the opening in the bottom of the outer vessel. When it is required to use the machine as a hydroextractor or for the atmospheric oxidation of such dyestuffs as sulphide or indanthrene colours, the shaft is lowered, whereby the cone is withdrawn and the cage may be revolved. The circulation of the air is assisted by a fan fixed to the upper part of the shaft, or by other means. An arrangement of pump, pipes and three-way cocks, whereby the liquors may be circulated in either direction without changing the direction of the pump, is described and illustrated.—F. M.

Dyeing furs, hair, feathers, and analogous material; Process for —. Farbwerke vorm. Meister, Lucius, and Brünig, Ger. Pat. 209,121, March 8, 1908. Addition to Ger. Pat. 149,676, April 2, 1903.

FURS, hair, feathers, etc., are dyed grey to black shades by treatment with *p*-aminotolyl-*p*-hydroxyphenylamine, in presence of oxidising agents such as hydrogen peroxide. The diphenylamine derivative is obtained by reducing the indophenol produced by the simultaneous oxidation of *o*-toluidine and *p*-aminophenol.—T. F. B.

Red dyeings on fibres; Process for producing — fast to light and washing. Farbwerke vorm. Meister, Lucius, and Brünig, Ger. Pat. 209,576, May 16, 1907.

THE oxidation products of thioindigo (see U.S. Pat. 898,738 of 1908; this J., 1908, 1015) are dissolved in solutions of normal alkali sulphites. By treating fibres with this solution, drying, and developing by means of warm, dilute mineral acids, fast red dyeings are produced.—T. F. B.

Discharge effects on union fabrics; Process for producing coloured —. Englische Wollenwaren-Manufaktur (vorm. Oldroyd und Blakeley), Ger. Pat. 208,998, Nov. 12, 1907.

THE cotton in union fabrics is dyed by means of dyestuffs reduced with difficulty (e.g. sulphide dyestuffs) whilst the wool is dyed with readily reduced dyestuffs; the discharge effects are produced by printing on the fabric a discharge paste, preferably free from tannin.—T. F. B.

Thioindigo Red dyeings; Process for discharging —. Kalle und Co. Ger. Pat. 209,122, June 7, 1907. Addition to Ger. Pat. 200,927, Jan. 18, 1907. (See Fr. Pat. 394,558 of 1908; this J., 1909, 241.)

FABRICS dyed with Thioindigo Red are printed with mixtures containing hydrosulphites and anthraquinone, and the leuco-compound is then removed as described in the principal patent; the addition of anthraquinone prevents the re-oxidation of the leuco-compound.—T. F. B.

Reserves under Aniline Black; Production of coloured — by means of mordant dyestuffs. Fabr. de Prod. Chim. de Thanu et de Mulhouse. Ger. Pat. 209,381, June 29, 1907.

COLORRED reserves under Aniline Black are obtained by printing the fabric with a paste consisting of the dyestuff, a chromium salt, ammonia, glycerin or similar substance, a thickening agent, and powdered chalk, steaming, treating with the aniline solution, and developing the black in the usual manner.—T. F. B.

Textile fabrics; Process for treating —. G. Hoinkes, Aussig-on-the-Elbe, Bohemia. Eng. Pat. 10,316, May 12, 1908.

IN the ordinary "crabbling" process, in which the material is sealded with boiling water or rolled on perforated cylinders and steamed, certain fabrics show cloudy or moiré effects, or become glazed. To obviate these defects it is proposed to pass the goods round cylinders, which are heated by steam at from $\frac{1}{2}$ up to 6 atmospheres pressure and are partially immersed in boiling water.—F. M.

Calendering machines. J. P. Bemberg Akt.-Ges., Barmen Rittershausen, Germany. Eng. Pat. 27,978, Dec. 23, 1908. Under Int. Conv., Jan. 8, 1908.

THE characteristic feature of this calendering machine is that the paper and steel rollers are held by bearing rollers and pressing rollers in a central position, and they are prevented from moving laterally by means of a stop. Both paper and steel rollers run at the same peripheral velocity as the bearing rollers. The bearings for the pressing and bearing rollers are arranged to oscillate in order to distribute the pressure evenly. An arrangement is provided to prevent any tipping or tilting of the bearings of the pressure and bearing rollers.—F. SHDN.

Waterproof and fireproof material or fabric. A. Mayhew. London. Eng. Pat. 10,771, May 18, 1908.

FOR producing resilient and inodorous waterproof and fireproof material or fabrics, suitable for scenery, floor-covering, bed-sheeting, cycle and motor tyres, etc., it is proposed to cover knitted or woven vegetable fabrics with a composition made by mixing a solution of glue or gelatin with glycerin, evaporating the mixture until it has the consistency of molasses, and mixing with it a hot concentrated solution of chrome alum or potassium bichromate. The hot mixture is spread, brushed or calendered on to the fabric and allowed to set under the influence of light. Another suitable composition is said to be obtained by acting upon starch with a solution of magnesium chloride.—F. M.

Vacuum drying apparatus. E. W. Strohn, Buffalo, N.Y. U.S. Pat. 921,307, May 11, 1909.

THE apparatus consists of a vacuum chamber within which a number of heating chambers are arranged. The web of material to be dried is wound on a drum at one end of the vacuum chamber and is unrolled and caused to pass by means of guide rolls around and between the heating chambers and finally wound upon a receiving drum situated at the other end of the vacuum chamber. A second web of material is simultaneously wound upon the receiving drum to keep the layers of dried material from touching each other.—W. H. C.

Dyestuffs; Fixation of — on fibre. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 9651, May 4, 1908.

SEE Fr. Pat. 391,388 of 1908; this J., 1908, 1150.—T. F. B.

Printing on textile fabrics; Process for —. L. Caberti, and Manifattura e Stamperia Lombarda, Novara, Italy. Eng. Pat. 7201, April 1, 1908. Under Int. Conv., April 2, 1907.

Sodium peroxide composition for washing and bleaching. Eng. Pat. 1150. See XII.

Objects from cellulose acetate. U.S. Pat. 922,340. See XIX.

VII.—ACIDS, ALKALIS, SALTS, AND NON-METALLIC ELEMENTS.

Sulphuric acid; Concentration of —. H. Friedrich. Chem.-Zeit., 1909, 33, 634. (See this J., 1909, 520.)

THE unsatisfactory point in most systems of concentration is the amount of weak acid (of about 20° B.) obtained by condensing the vapours from the concentrating apparatus. In order to reduce the quantity of this weak acid, the author proposes that the vapours from the concentrating apparatus be passed through a small tower, similar to a Glover tower, down which chamber acid is allowed to trickle, the supply being so regulated that the vapours leaving the tower have a temperature of about 100° C. The acid from the tower is passed to the concentrating apparatus.—A. S.

Caro's acid. R. Willstätter and E. Hauenstein. Ber., 1909, 42, 1839—1850.

CARO'S acid has been regarded from different sides as a dibasic peranhydrosulphuric acid, $H_2S_2O_8$, and as a monobasic sulpho-monoper-acid, H_2SO_5 . The authors have succeeded in preparing acyl compounds of the acid by the action of benzoyl chloride and benzene sulphochloride on the potassium salt. These acyl compounds, $C_6H_5.CO.O.O.SO_3H$, and $C_6H_5.SO_2.O.O.SO_3H$, contain 1 acyl group for each atom of sulphur, and are of an acid character, being obtained in the form of potassium salts, and hence Caro's acid must be sulpho-monoper-acid, H_2SO_5 , for the acyl compounds of peranhydrosulphuric acid (Acyl) $_2S_2O_8$, would not be acids. (See also Ahle, this J., 1909, 363.)—A. S.

Potassium nitrate; Production of — by the interaction of sodium nitrate and potassium carbonate. R. Kremann and A. Zitek. Monatsh. Chem., 1909, 30, 311—340.

IN the authors' experiments to determine the conditions under which the maximum yields of potassium nitrate and of sodium carbonate (as by-product) might be obtained, the salts or mixtures of them were shaken with water in a closed flask and kept in a thermostat at the required temperature until the liquid was saturated. A definite amount of the supernatant liquid was then withdrawn by means of a filter-pipette and analysed. The amount of carbonic acid was found by titration, the potassium and sodium determined in the usual way, and the nitric acid found by difference. Series of determinations were made at 24.2° C. and 10° C., and the solubilities of the various salts involved in the reactions are given in tabular form and expressed graphically by Löwenherz's method (Z. physik. Chem., 13, 459). The results show that the solubility of pure sodium carbonate is reduced by the addition of sodium nitrate, but not constantly, owing to the fact that up to a certain point the deposit contains the hydrate, $Na_2CO_3 \cdot 10H_2O$, but that subsequently this is transformed into the hydrate, $Na_2CO_3 \cdot 7H_2O$. In the case of pure sodium carbonate solutions this change takes place at 31.85° C., but in the presence of a second soluble substance the temperature is lower. Hence at 24.2° C., given a certain degree of concentration of the sodium nitrate, the deposit of sodium carbonate will contain 7 mols. of water of crystallisation. The solubility of pure sodium nitrate decreases, in accordance with the general rule, on the addition of sodium carbonate. On the other hand, the addition of sodium nitrate to a solution already saturated with potassium nitrate increases the solubility of both salts, possibly owing to the formation of a double nitrate. The addition of potassium carbonate to a saturated solution of potassium nitrate causes a fairly rapid reduction in the amount of potassium carbonate dissolved. On the gradual addition of potassium carbonate to a saturated solution of sodium carbonate, the solubility of the latter is increased up to a certain point, after which it rapidly falls. The solution at this point yields, on concentration, a double salt, $Na_2CO_3 \cdot K_2CO_3 \cdot 6H_2O$. In the corresponding experiments at 10° C. the sodium carbonate in the deposit invariably contained 10 mols. of water, and the change observed at

24.2° C. into a salt containing 7 mols. of water did not take place. The solubilities of sodium carbonate and potassium nitrate were reduced to a relatively large extent by the reduction of temperature, whilst the solubilities of potassium carbonate and sodium nitrate were only slightly affected. At the temperatures mentioned sodium nitrate and potassium carbonate cannot co-exist, and saturated solutions can therefore only contain: (1), potassium nitrate, sodium carbonate, and sodium nitrate; (2), the double salt, $\text{KNO}_3 \cdot \text{Na}_2\text{CO}_3$; and (3), the double salt, $\text{KNO}_3 \cdot \text{K}_2\text{CO}_3$. *Technical application.*—In utilising this reaction for technical purposes it is essential that after separation of the potassium nitrate the solution shall give the maximum yield of sodium carbonate. If, after separation of the potassium nitrate, the supernatant liquid contains per 1000 c.c. the corresponding equivalents in grms. of the ions, CO_3 , $(\text{NO}_3)_2$, K_2 and Na_2 , the utilisation coefficients of potassium and sodium may be found by the respective formulae:—

$$U_K = \frac{100(\text{CO}_3 - \text{K}_2)}{\text{CO}_3}$$

and

$$U_{Na} = \frac{100(\text{Na}_2 - (\text{NO}_3)_2)}{\text{Na}_2}$$

At a point, P_2 , representing the stage at which the liquid is saturated with sodium carbonate, potassium nitrate and double salt, the utilisation coefficients of both products are better than at the point, P_1 , (saturation with sodium nitrate, sodium carbonate and potassium nitrate), or than at a point, P_3 , at which the solution is saturated only with potassium nitrate. This is illustrated by experiments of which the following are typical:—

	Solubility in 1000 c.c. of water. grms.				Solubility in 1000 c.c. of water. grms.				Solubility in 1000 c.c. of water. grm.-mols.				Utilisation coefficients.	
	Na_2CO_3	K_2CO_3	NaNO_3	KNO_3	Na_2	K_2	CO_3	NO_3	Na_2	K_2	$(\text{NO}_3)_2$	CO_3	U_K	U_{Na}
P_1 ..	21.7	—	709	282	286	109	123	704	6.22	1.40	5.68	2.05	31.7	8.6
P_2 ..	37.7	2	—	232	164	90	213	142	3.57	1.15	1.14	3.55	67.6	68.0
P_3 ..	7.787	101.49	—	3.154	33.8	586.8	484.4	19.4	0.74	7.52	0.16	8.07	6.8	78.4

In an experiment based on these considerations, 29.5 grms. of sodium nitrate and 24.5 grms. of potassium carbonate were shaken with 50 c.c. of water at 24.2° C., and allowed to stand at the same temperature. The deposit, freed by expression from the mother liquor, consisted of 24 grms. of potassium nitrate (containing 4.5 per cent. of carbonate). This corresponded to a yield of 23.0 grms. of the pure salt (theory: 23.6 grms.). In practice on a large scale the adhering carbonate would be more effectually expressed. The sodium carbonate in the residual liquor may be recovered by adding sufficient sodium nitrate to make the composition correspond with that of a solution at the point, P_1 . The solution at the point, P_2 , contains no nitrate, and the addition of sodium nitrate reduces the solubility of the sodium carbonate to such an extent that it separates out. Whereas at the point, P_2 , the solubility of sodium carbonate is 37.7 per litre, at the point, P_1 , it is only 21.7 per litre. The potassium nitrate cannot separate, for its solubility increases towards the point, P_1 , as is shown in the figures given above. To obtain a solution corresponding to one at P_1 , more potassium carbonate must also be added, and this will react with the excess of added sodium nitrate to form sodium carbonate and potassium nitrate, the former of which separates out, whilst the latter remains in solution. In the above-mentioned experiment 70 grms. of the solution, after separation of the potassium nitrate, contained 46 grms. of water and 24 grms. of solid matter. The difference per litre in the amounts of NO_3 and K between P_1 and P_2 in the table given above, calculated for 46 grms. of water, corresponds to 35.4 grms. of sodium nitrate and 0.6 grm. of potassium carbonate. On adding these quantities to the 70 grms. of the solution, a deposit consisting of sodium carbonate containing 1 mol. of water was obtained. Water corresponding to this amount of

water of crystallisation (1.25 grms.) was therefore added, and the flask shaken for about a day. A deposit weighing 7.07 grms. (theory 7.36 grms.) of anhydrous 99.1 per cent. sodium carbonate was now obtained. Experiments to determine the influence of temperature on the technical application of the reaction showed that at 10° C. the utilisation coefficients were smaller than at about 25° C. It is therefore preferable, in practice, to filter the solution at higher temperatures, say at about 25° C.—C. A. M.

Chlorides; Detection of — in the presence of complex cyanides and other halides. W. Böttger. *Z. anal. Chem.*, 1909, 48, 356—368.

For the detection of chlorides, even in small quantity in the presence of complex cyanides and other halides the following method is given:—0.5 grm. of the mixture is decomposed by boiling for a few minutes with 10 c.c. of 2N sulphuric acid, 20 c.c. of water, and mercuric oxide (3 parts for every part of complex cyanide); the mercury is then precipitated from the cooled solution by hydrogen sulphide; hydrogen cyanide and hydrogen sulphide are expelled by a current of well-washed carbon dioxide, passed through the warm filtered liquid for at least 20 minutes, and silver nitrate is added. In the case of a ferrocyanide, the ferrous salt remaining after this treatment must be oxidised by permanganate, before testing with silver nitrate. In the presence of a bromide, a larger proportion of mercuric oxide, sufficient to react with this also, must be used, and, after driving off the hydrogen cyanide and hydrogen sulphide as above, the bromine ions are oxidised by warming with permanganate and adding alcohol in the usual way, carbon dioxide being passed through the warmed filtrate to gel

rid of the aldehyde and excess of alcohol; when dealing with a ferrocyanide, permanganate must then again be added to the cooled liquid, before adding silver nitrate.

—F. SODX.

Bauxite; Composition of —. H. Arsandaux. *Compt. rend.*, 1909, 148, 1115—1118.

THE author has analysed a number of French bauxites by determining the constituents soluble and insoluble in concentrated hydrochloric acid, when heated on the water-bath for one hour. These minerals were composed essentially of monohydrated aluminium oxide, $\text{Al}_2\text{O}_3 \cdot \text{H}_2\text{O}$, ferric oxide, very nearly anhydrous, titanium oxide, apparently in the form of metatitanic acid, and silica, certainly in the form of a hydrated aluminium silicate, $\text{Al}_2\text{H}_4\text{Si}_2\text{O}_9$. The ferric oxide was found to be completely soluble; sometimes also traces of titanium oxide and silica dissolved; in most cases the aluminium oxide was practically resistant, but in the bauxites rich in silica, appreciable quantities of alumina were soluble. The bauxites were found to contain an amorphous silicate having the composition of kaolinite (halloysite). They may therefore be regarded as rocks more or less argillaceous in character, whilst the extreme type corresponds approximately with a true clay. In the insoluble portion, after allowing for the hydrated aluminium silicate, the molecular ratio of combined water to aluminium plus titanium oxides is generally near unity, but always more or less above it. The higher values for this ratio are found in the more silicious specimens, indicating a tendency towards a higher state of hydration of the aluminium oxide than the monohydrate. In the extreme types of silicate bauxites the combined water of the aluminium oxide approximates to the dihydrate. The bauxites may be

considered as argillaceous rocks graduating towards types poorer in silica and richer in free aluminium oxide in the form of monohydrate. This monohydrate, $\text{Al}_2\text{O}_3 \cdot \text{H}_2\text{O}$, may be regarded as the stable form and the ultimate term of the decomposition of the feldspars.

—J. F. B.

Lead sulphate; Solubility of — J. Schnal. Compt. rend., 1909, 148, 1394—1396.

THE solubility of lead sulphate in water is the same at different temperatures, but equilibrium is reached more rapidly at high than at low temperatures. Pure water dissolves 0.0824 grm. per litre, or 1 part of salt dissolves in 12,135 parts of water. As sulphuric acid is added to the water, the solubility diminishes, till with 1 part of sulphuric acid per 1000, the salt is absolutely insoluble. Lead hydroxide dissolves in water to the extent of 0.1385 grm. per litre; in water containing 0.0265 part of sulphuric acid per 1000, to the extent of 0.0824 grm. per litre, the same solubility as that of lead sulphate in water. The author considers, therefore, that lead sulphate is itself insoluble, but when brought into contact with water it is slowly converted into sulphuric acid and lead hydroxide, which dissolves till the amount of sulphuric acid formed is enough to cause equilibrium in the reaction,

—J. T. D.

Cuprous sulphate. A. Recoura. Compt. rend., 1909, 148, 1105—1108.

CUPROUS sulphate may be readily prepared by the action of dimethyl sulphate on cuprous oxide under anhydrous conditions. In a small flask, provided with an evolution tube dipping under mercury, 2 grms. of porphyrised cuprous oxide and 20 c.c. of dimethyl sulphate are heated at 160° C. with frequent agitation. The oxide turns greyish-white in colour and a copious evolution of methyl ether occurs. As soon as the evolution of gas ceases, the heating must be stopped, otherwise cupric sulphate will be formed by the further action of the dimethyl sulphate. The cuprous sulphate is washed with anhydrous ether and the ether is evaporated in a vacuum desiccator. The product is unchanged by contact with air so long as it is covered by a layer of ether, but oxidises if the latter evaporates in presence of air. Cuprous sulphate is a greyish-white powder, unalterable in dry air but immediately decomposed by water into cupric sulphate and metallic copper. The heat evolved in this dissociation is 5.2 calories, the product being considered anhydrous. In many of its reactions cuprous sulphate behaves like a mixture of nascent copper and cupric sulphate. It oxidises only slowly in moist air, but rapidly if flooded with ether, to form a black substance. When brought in contact with water this product immediately gives a solution of cupric sulphate and a precipitate of a black oxide which shows all the characters of Rose's suboxide, Cu_2O . When heated in the oven at 200° C. until the weight is constant, cuprous sulphate absorbs 1 atom of oxygen and is converted into a mixture of cupric oxide and cupric sulphate. Concentrated hydrochloric acid and ammonia both dissolve cuprous sulphate giving solutions of cuprous salts; glacial acetic acid also dissolves small quantities giving an intense violet solution which rapidly oxidises in the air.—J. F. B.

Thio-oxalates. H. O. Jones and H. S. Tasker. Chem. Soc. Proc., 1909, 25, 159—160.

THE esters of dithio-oxalic acid are readily prepared by the action of alkyl hydrosulphides on oxalyl chloride; the dimethyl, diethyl, and diphenyl esters are crystalline, and show a distinct yellow colour (the diphenyl compound is a bright sulphur-yellow). These esters are decomposed by hot potassium hydroxide solutions into potassium oxalate and alkyl hydrosulphide, but when heated with a concentrated alcoholic solution of potassium hydro-

sulphide a white solid separated, which was found to be potassium dithio-oxalate, $(\text{KSCO})_2$. This salt is white and crystalline, and is very soluble in water, giving a yellow solution, from which it separates in colourless prisms when evaporated on the water-bath. The salt gives intense colours with solutions of certain metallic salts, and precipitates with others; some of these precipitates decompose on heating, yielding the sulphide of the metal. The most striking reactions are those given with solutions of nickel and cobalt salts, the former give an intense magenta colour, the latter a deep brown colour, in both cases so intense as to be visible in solutions containing one part of the metal in 8,000,000 parts of solution. The coloured compound formed with nickel can readily be obtained in small, black, lustrous needles, resembling small crystals of potassium permanganate; these were found to have the composition required by the formula $\text{C}_2\text{O}_3\text{S}_2\text{K}_2\text{Ni}$. Solutions of this salt and the cobalt salt are stable to acids, and the metals are only precipitated very slowly from them by the addition of potassium hydrosulphide or hydroxide.

Potassium monothio-oxalate is prepared by the action of alcoholic potassium hydrosulphide on diethyl monothio-oxalate, $(\text{COSC}_2\text{H}_5 \cdot \text{CO}_2\text{C}_2\text{H}_5)$, and separates slowly in white needles, which contain one molecule of water of crystallisation. This salt is also very soluble in water, but gives a colourless solution; the solution decomposes on addition of acid, and gives colours and precipitates with metallic salts which are very similar to those given by the dithio-oxalate, but the insoluble salts are in this case more readily decomposed. The corresponding acids are unstable, and have not yet been isolated in the pure state.

Utilising furnace gases poor in sulphur dioxide. Borchers. See X.

Sodium sulphate deposit in California. Oil, Paint, and Drug Rep., May 31, 1909. [T.R.]

LARGE deposits of sodium sulphate are found in the lowest portion of the Carriso Plain, which extends along and within the north-east boundary of San Luis Obispo County, California. The lake known locally as Soda Lake, or Salt Lake, in the bed of which this salt occurs, receives the drainage from the Carriso Plain and the adjoining flanks of the bounding ranges, the total catchment basin being somewhat over 525 square miles in extent. The lake includes an area of nearly 3000 acres. It remains practically dry except in extraordinarily wet seasons. A sample of the salt collected at the surface of the lake, near the present evaporation plant, varies from dull to lustrous pure white in colour, and, though more or less granular, may be easily crushed between the fingers. An analysis of the salt made in the laboratory of the U.S. Geological Survey shows it to contain 49.5 per cent. of sodium oxide (Na_2O), 46.12 per cent. of sulphuric anhydride, 1.66 per cent. of magnesium oxide, and 9.27 per cent. of chlorine. The nearest railway station is 15 miles away, across a mountain range, another and more accessible one being 32 miles distant. Until the contemplated railway to San Luis Obispo is constructed, the profitable working of the deposits appears impossible.

Monazite production of the United States. Mining World, June 5, 1909. [T.R.]

THE production of crude monazite sand in the United States during 1908 amounted to 1,521,866 lb., averaging about 25 per cent. monazite. The crude concentrates yielded 422,646 lb. of refined sand, averaging about 90 per cent. monazite and valued at \$50,718, or 12 cts. per pound. Of this production North Carolina yielded 310,196 lb., valued at \$37,224, and South Carolina, 112,450 lb., valued at \$13,494.

The following table gives the production in pounds and value of monazite from 1893 to 1902, inclusive; of monazite and zircon in 1903; of monazite, zircon, adolinite, and columbite in 1904; of monazite, zircon, and columbite in

Titanium oxides; Production of —. F. A. J. Fitzgerald and P. M. Bennie, Niagara Falls, Assignors to General Electric Co., New York. U.S. Pat. 921,686, May 18, 1909.

CRUSHED ilmenite or other titanite iron ore, mixed with powdered carbon, is heated to about 1800° C., at which temperature the iron oxide only is reduced. The resulting sintered mass is crushed and the reduced iron removed by magnetic separation and treatment with acid.

—F. SODN.

Sulphur; Extraction of — from spent iron oxide [used in coal gas purification]. P. E. Williams, Leytonstone. Eng. Pat. 596, Jan. 9, 1909.

"SPENT oxide," which is a mixture of iron sulphide and sulphur, is treated with a strong ammoniacal solution, whereby the free sulphur reacts with the ammonia to form ammonium polysulphide. After filtering, the remaining iron sulphide is converted into ferric oxide and sulphur by exposure to the air, and the resulting mixture is again treated with ammonia. Sulphur is obtained from the ammonium polysulphide solution by boiling, the escaping ammonia being either mixed with the crude coal gas before it passes into the purifying boxes, or recovered in any other suitable manner.—O. R.

Hydrogen trisulphide and hydrogen disulphide; Process for the preparation of pure — and of mixtures of the two. I. Bloch. Ger. Pat. 209,860, Jan. 12, 1908.

CRUDE hydrogen persulphide obtained from inorganic or organic polysulphides is distilled *in vacuo*, and the distillate collected in two receivers, the first being kept at 5°–25° C. (preferably 10–20° C.) and the second at +5° to –60° C. (preferably –10 to –50° C.). The first receiver then contains pure hydrogen trisulphide, and the second, hydrogen disulphide containing a little trisulphide, which can be removed by a second distillation. Mixtures of hydrogen disulphide and trisulphide can be obtained by using a receiver cooled to +5 to –60° C., or two receivers, one kept at 25–50° C. and a second cooled to about –60° C. Hydrogen disulphide can be prepared by distilling hydrogen trisulphide *in vacuo*, and collecting the distillate in two receivers kept at 5–25° C. and +5° to –60° C. respectively. (See also his J., 1908, 748.)—A. S.

Oxygen; Process and apparatus for the extraction of atmospheric —. A. M. Descours-Desaerens. Fr. Pat. 396,889, Feb. 7, 1908.

ATMOSPHERIC air is subjected to a continuous cycle of operations consisting of dissolving it in water under pressure, whereby a gaseous mixture richer in oxygen is obtained in solution, removing the undissolved gas richer in nitrogen, and subsequently diminishing the pressure on the solution, whereby the dissolved gas is again set at liberty. By repeating the process a sufficient number of times, almost pure oxygen is obtained. The apparatus consists of a battery of reservoirs and compressors so arranged that, when the pressure in any one of the reservoirs reaches a certain amount, the undissolved gas is eliminated, while the liquid passes automatically into the next reservoir, where, under diminished pressure, the previously dissolved gas is set free, and the process is then repeated.—O. R.

Sulphuric acid; Manufacture of —. Erste Oesterr. Sodafabrik, and C. Opl. Hruschau, Silesia. Eng. Pat. 20,171, Sept. 25, 1908.

VIII.—GLASS, POTTERY, AND ENAMELS.

Glass; Permeability of — for gases [iodine vapour]. A. Stock and H. Heynemann. Ber., 1909, 42, 1800–1801.

A LEAF of silver foil was sealed up in an ordinary glass flask, which was first evacuated completely. In a second flask a piece of silver foil was also placed, the flask then evacuated as before, but filled with water-vapour at 5 mm. pressure before sealing. Both flasks were then left for 3 months in a closed vessel containing iodine crystals. The silver foil remained perfectly bright in both cases, and after opening the flask and dissolving the foil in pure nitric acid not a trace of residue remained, showing that no iodine had passed through the glass. These results are at variance with those obtained by C. Zenghelis (Z. physik. Chem., 1909, 65, 341).—E. F.

Glass-cutting by means of an electric wire. F. L. Jouard. J. Amer. Chem. Soc., 1909, 31, 654.

THE glass is scratched with a file or on an emery wheel in order to provide a starting point for the crack, and a thin resistance wire is then wound around the part it is desired to crack, the wire being drawn taut and a piece of asbestos paper inserted between the crossed ends to prevent contact. The ends of the wire are connected to a source of electricity, and a current passed through sufficient to heat the wire to dull redness. The crack follows exactly the path of the resistance wire.—A. S.

Silicates, glasses, and glazes; Formation of —. J. W. Cobb. Chem. Soc. Proc., 1909, 25, 165–166.

ON the assumption that a glass can be regarded as formed by the combination and solution of its constituent oxides, the author has studied the process of formation of the glass represented by the formula, $\text{Na}_2\text{O} \cdot \text{CaO} \cdot \text{Al}_2\text{O}_3 \cdot 10\text{SiO}_2$. An investigation on the combination of lime and silica shows that the compounds formed are $2\text{CaO} \cdot \text{SiO}_2$ and $\text{CaO} \cdot \text{SiO}_2$. Lime and alumina interact to form the compounds, $\text{CaO} \cdot \text{Al}_2\text{O}_3$, $\text{CaO} \cdot 2\text{Al}_2\text{O}_3$, and an insoluble calcium aluminat, presumably containing a large amount of alumina.

The general question of chemical interaction between solids was discussed, and the conclusion was drawn that: (1) the temperature of formation of a slag and its fusion point are not identical, nor are they apparently related (in opposition to Bondouard's generalisation); (2) interaction between solids may go far, even to completion, without fusion; (3) from 800 upwards the state of mixed solid particles is one of fairly effective molecular contact, allowing free play to selective chemical affinities.

Porcelain; Preparation of — from its constituents. H. Bollenbach. Sprechsaal, 1909, 42, 332–333.

THE most important ingredient in porcelain is the "clay-substance," $2\text{SiO}_2 \cdot \text{Al}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$. The purest source of this is Zettlitz kaolin, but a week's washing is required to remove alkalinity. Attempts to synthesise clay-substance have hitherto failed, the product being a non-plastic mass yielding bodies which melt at a lower temperature than they would had they been made with the natural clay. In glazes, it is known that the substitution of aluminium hydroxide and silica for kaolin is the best method for obtaining "craquelé" ware, but the author claims to have replaced kaolin by its constituents in glazes free from hair-cracks. In a porcelain made from 28 parts of felspar, 25 of quartz, 45 of Zettlitz kaolin, and 2 of bone-ash, the spar was now replaced by an artificial

frit made from 16 parts of aluminium hydroxide, 7 of potassium carbonate, 10 of potassium nitrate, and 36 of Hohenboeck sand, and the kaolin was replaced by sand and aluminium hydroxide, the mixture being made plastic by a rye-meal paste. The results are said to be identical with the porcelain made from natural sources. Zoellner (this J., 1908, 448) found that a porcelain fired at cone 16 is composed of crystals of sillimanite, $Al_2O_3 \cdot SiO_2$, mixed with strongly-attacked particles of quartz and full of bubbles. A porcelain fired at cone 12 contains partially-attacked particles of quartz, melted spar, and an amorphous silicate which may be anhydrous clay-substance, $Al_2O_3 \cdot 2SiO_2$.—H. H. S.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Portland cement; Water content of set — in the course of hardening. D. Nagy. *Tonind-Zeit.*, 1909, 33, 615.

PORTLAND cement was made into a paste with various proportions of water, shaped into cubes, and the latter were bored after remaining in air and in water for definite periods. The borings were then analysed for hygroscopic water, water of hydration, and carbon dioxide. It was found that set cement lost its hygroscopic water gradually the longer it was kept, both in air and under water. The amounts of water of hydration and of carbon dioxide, on the other hand, in general increased with age, except in the case of set cement exposed to the air, in which the water of hydration reached a maximum after a certain period, and then began to decrease again. This period seemed to lie between 128 and 187 days. Even after 11 months the chemical constitution of set cement was not yet constant, and the author concludes that the volume changes, which take place in consequence of hydration and carbonation, are of a molecular nature and expel the hygroscopic water, thus accounting for the apparent "drying" of cement under water.—O. R.

PATENTS.

Kiln for burning limestone, dolomite, and the like. E. Schmatolla, London. Eng. Pat. 28,549, Dec. 31, 1908.

Is a gas-fired, vertical, shaft kiln, a main gas channel is in direct communication with the gas producer or producers, and intermediate between lower and upper gas channels. The shaft is rectangular in section, with rounded corners, and is divided towards the bottom into two separate chambers by means of a bevelled crossbridge. Four straight gas channels, having openings at their outer ends, cross each other at right angles and communicate with outer or upper gas inlets by means of short flues arranged in the arches of the gas channels, and with the central gas inlet by means of flues in the floors of the gas channels. The arrangement of the central gas channel is such that it is accessible at both ends from the outside through doors, so that it may easily be cleaned, and a series of port holes above the upper gas inlets allows the burning to be watched and any material that may have stuck in the shaft to be dislodged from the outside.—O. R.

Firebrick and the like; Composition of matter for use in — and process of producing the same. L. Houze, Assignor to C. F. Niklaus, R. H. Willey, and A. Brant, Monterey, Cal. U.S. Pat. 921,838, May 18, 1909.

HYDROPHANE, or a similar rock, is roasted, crushed coarsely, and mixed with fireclay; the mixture is moulded and burnt.—A. G. L.

Wood; Process for neutralising solutions used for impregnating —. B. Diamond. Fr. Pat. 396,974, Nov. 3, 1908.

THE waste liquors obtained in the manufacture of cellulose by the sulphite method are made alkaline with sodium carbonate, filtered, and added to the saline solutions used for impregnating wood.—O. R.

X.—METALS AND METALLURGY.

Iron oxide; Melting-point of —. E. J. Kohlmeier. *Metallurgie*, 1909, 6, 323—325.

THE oxide, previously sintered together by a short heat at 1270° C. in an atmosphere of oxygen, was introduced into a platinum crucible placed in an electrically-heated spinel (magnesium aluminate) crucible, which was kept at about 1600° C. until the oxide was completely melted when it was allowed to cool. The melting point of ferrous oxide was determined by the aid of a cooling curve constructed on the basis of the observation of the degree of rate of cooling. A current of oxygen was passed through the platinum crucible during the experiments. Two determinations on different specimens of ferrous oxide gave melting-points of 1565° and 1562° C. respectively, with ill-marked arrest-points at 1350°—1250° and well-defined arrest-points at 1035° and 1028°. The oxides used contained, after sintering, 3—4 per cent. of ferrous oxide and slightly more after melting. The specific gravities after melting, were 5.187 and 5.193; the fused product was strongly magnetic. A similar determination of magnetic iron oxide (Fe_3O_4) gave a melting-point of 1527° C., and an arrest-point at 1350—1250.—A. G. L.

Silicon and its influence on the electrical and magnetic properties of iron. E. Kolben, Runds. f. Technik u. Wirtschaft; through *Engineering*, 1909, 87, 732—733.

THE results of the author's experiments on the influence of silicon on the mechanical, electrical, and magnetic properties of low-carbon iron, are shown in the following table:—

	A.	B.	C.	D.	E.
Percentage of silicon—					
Minimum	0.026	1.07	2.28	—	3.50
Maximum	0.30	1.54	3.15	3.25	3.53
Tensile strength in kilos. (sheets 0.5 mm. thick)	30.8	35.1	47.3	—	61.0
Elongation, per cent.	11.0	7.5	6.0	—	3.5
Electrical resistance, ohms.	0.118	0.287	0.355	0.50	0.595
Increase in resistance per 100° C., per cent.	41.0	19.0	14.0	7.5	2.0
Coefficient of hysteresis.	0.0015	0.0014	0.0010	0.0009	0.000
Hysteresis, watts per kilo.	2.5	2.2	1.65	1.45	1.45
Eddy currents, watts per kilo.	1.3	0.8	0.7	0.6	0.4
Permeability, B for H = 140	17,600	17,300	17,000	16,700	16,400

THE alloys containing 3.5 per cent. of silicon have low temperature-coefficient of electrical resistance, and it is proposed to use alloys of iron containing from 2 to 6 per cent. of silicon and up to 5 per cent. of aluminium for the manufacture of resistances capable of replacing nickel, German silver, and similar alloys. The magnetic properties of iron are, on the whole, favourably influenced by silicon, the watt losses being considerably reduced and the effect of ageing counteracted, whilst the permeability is not much affected. The alloys are however difficult to work, and with 3 per cent. of silicon are very brittle. The brittleness, whilst not of much consequence with respect to the use of the alloys in transformers, would preclude their employment in dynamos.—A. S.

Cyanide solutions; Precipitation of gold from — by carbonaceous matter (in lime). W. A. Caldecott. *Chem. Met. and Min. S. S. Africa*, 1909, 9, 327—330.

EXPERIMENTAL tests on the effect of partly burnt coal in contact with auriferous cyanide solutions showed that it was practically as efficient a precipitant as charcoal, although unburnt coal had little effect. The ordinary lime used in cyaniding, which has been prepared by firing in kilns alternate layers of limestone and fuel, is generally contaminated with traces of partly consumed coal or charcoal, and assuming that only a fraction of one per cent. is present in the lime used, on a large cyanide plant this would represent several pounds of precipitant per day.

with an equivalent loss of gold. If retort lime cannot be procured, it is suggested that the lime should be dissolved in the mill-service water before entering the battery, time being allowed for the removal of impurities by settling. Many millmen, however, consider that much lime in the mill water has a deleterious effect on the plates, besides causing the possible choking up of the pipes leading to the mill.—F. R.

Mercury [in ores]; Volumetric determination of —. W. H. Seamon. Eng. and Min. J., 1909, 87, 1047—1048.

0.5 GRM. of the finely ground ore (200-mesh) is digested with 5 c.c. of concentrated hydrochloric acid for 5—10 minutes at 40° C. and then 3 c.c. of concentrated nitric acid are added and the heating continued for a few minutes at the same temperature, until all the cinnabar is decomposed. Lead is not usually found in mercury ores, but if present, 3 c.c. of strong sulphuric acid are added to precipitate it from solution. As free chlorine must be absent and it cannot be removed by boiling owing to the loss of mercuric chloride by volatilisation, 5 c.c. of strong ammonia are added drop by drop, followed by 25 c.c. of water. The precipitate is filtered off, washed twice with a minimum amount of water, and 2 c.c. of strong nitric acid, which has been exposed to strong light to produce some nitrous acid, are added to the filtrate. When cool, a third of the solution is set aside and the remainder titrated with a standard solution of potassium iodide, using drops of starch paste on a tile for an indicator. When a definite end reaction has been obtained, the reserved portion of the assay is added, and titration continued until a drop added to the starch produces a faint blue coloration. 0.5 c.c. is deducted from the result if the bulk of the liquid is over 50 c.c. Mercuric chloride is employed for standardising the potassium iodide solution, the strength of the latter being 8.3 grms. per litre, 1 c.c. of which is equivalent to 0.005 gm. of mercury. The method is said to be quick and reliable, results agreeing within 0.1 per cent.—F. R.

Antimony alloys; Analysis of —. Nicolardot and Krell. Bull. Soc. Chim., 1909, 5, 559—562.

THE paper deals mainly with the separation of antimony and tin from the other metals contained in various alloys. It is recommended that the alloy be treated with nitric acid, the mixture evaporated to dryness, and the insoluble antimony and tin oxides then collected in a cylindrical filter constructed of porous porcelain. The oxides are washed with dilute nitric acid, dried, reduced to the metallic state by heating at 400° C. in a current of hydrogen, and weighed. The two metals are then separated from each other in the usual manner. Traces of copper which are occluded by the mixed oxides may be deposited electrolytically from the solution of the two metals.—W. P. S.

Calcium alloys as reducing agents; Further experiments with —. O. P. Watts and E. R. Suhm. Chem. News, 1909, 99, 257—259. (See also this J., 1908, 752.)

CONFLICTING results were obtained in the direct comparison of aluminium with the alloys as reducing agents, the action of the latter being too violent in many cases. The authors find that the alloys are distinctly superior to aluminium for the igniting mixture, and are of opinion that this is also the case in all the less violent reductions. The briquetting of the charge was found to be very effective in suppressing undue violence of reaction; and since the alloys richest in cerium and magnesium act with the greatest energy, the authors conclude that those containing only sufficient calcium or magnesium to render them easily pulverisable will be the most serviceable, as well as the cheapest. It was found possible to prevent vaporisation of molybdenum dioxide, during reduction, by causing it to combine with other oxides before the charge attained an extremely high temperature. Attempts to produce solid masses of tungsten and titanium, by various means, were unsuccessful.—W. E. F. P.

Cadmium in soft solders. E. S. Sperry. Brass World, May, 1909; Eng. and Min. J., 1909, 87, 1140.

By adding cadmium to ordinary soft solder, the melting point of the latter is lowered, and its strength increased.

An alloy containing 50 per cent. of tin, 25 of lead, and 25 of cadmium has been found most satisfactory; it melts at 144.5° C., or about 30° lower than the best soft solder (2 of tin to 1 of lead). In preparing it, the metals are melted together in presence of a small quantity of ammonium chloride as flux, and well stirred before pouring. With the present moderate price of cadmium, the cost of the solder is not greatly increased. The new solder is especially useful for soldering Britannia metal, pewter, antimonial lead, etc.—A. S.

Sulphur dioxide; Principles of a process for rendering furnace gases poor in — harmless and useful. F. Borchers. Metallurgie, 1909, 6, 316—319.

THE process is an extension of that of Hünisch and Schroeder (see this J., 1884, 570), and is especially applicable to poor gases containing less than 4 per cent. of sulphur dioxide from roasting-furnaces, and to localities poor in fuel. The process consists essentially in passing the cooled gases up two absorption towers. In the further of these towers the gases meet descending water, which absorbs all except traces of sulphur dioxide. The dilute solution of sulphur dioxide so obtained is passed, repeatedly if necessary, down the first tower, in which it meets the richer gases, and in which it attains a high degree of concentration. The solution so obtained is heated to 90° C., preferably by the hot furnace-gases, which are thus cooled before entry into the towers.—A. G. L.

Platinum industry of the Ural. Ch. of Comm. J., June, 1909. [T.R.]

THE French Ambassador at St. Petersburg reports that the production of platinum in the Ural, which amounted in 1908 to 298 pounds, was 31 pounds less than in 1907, and was obtained from the following districts: Tcherdyn, 14 pounds; Perm, 70 pounds; Verkhotourié, south, 186 pounds; Verkhotourié, north, 25 pounds; Ekaterinburg, south, 3 pounds. The production during 1908 was the lowest for 10 years, and 50 pounds less than the average of the last decade. The restriction of output which has been carried on by producers of platinum with the view of maintaining the price of the metal is the cause of the small production during last year. The mines of Prince Abamelek Lazareff, situated in the Solikamsk district, increased their output by five pounds. It is in the southern part of the Verkhotourié district that the reduction of output has been most marked; the production in the district was 231 pounds in 1907, or 45 pounds more than in 1908. The Nijné-Touryinsk mines, belonging to the Platinum Industry Company, and those of Nijné-Taguilsk in the same district, have also reduced their output. On the other hand in the northern part of the Verkhotourié district the production increased by over eight pounds owing to the installation of a new dredge at the Lialine mines and an increase of activity at the Nicholas-Pavdinsky mines. The mines of Count Chouvalov, in the Perm district, also increased their output by a little more than one pound, but the Sysert mines in the southern district of Ekaterinburg yielded slightly less than in the preceding year.

PATENTS.

Alloys; Metallic —. J. F. Duke, Shortlands, Kent. Eng. Pat. 12,042, June 3, 1908.

THE claim relates to the production of an alloy of the composition:—Copper, 1450; aluminium, 30; nickel, 20 parts. These properties may be slightly modified; thus a slight increase in the nickel content and proportional decrease of aluminium will increase the malleability and ductility of the alloy. The product is easy to work and may be alloyed with gold in all proportions. For general purposes an alloy having the approximate composition: Copper, 1441.50; aluminium, 39.75; nickel, 18.75 parts may be employed.—C. A. W.

Cobalt compounds [and cobalt]; Manufacture of —. The Mond Nickel Co., Ltd., R. Hirtz, and M. D. Cowap, London. Eng. Pat. 13,207, June 20, 1908.

CORALT carbonyls are prepared by heating finely divided cobalt in carbon monoxide under suitable conditions of

temperature and pressure (see this J., 1908, 1017). To extract cobalt from its ores, the latter are first converted into oxide and introduced into a steel tube lined with copper. The tube is heated to 250°–300° C. and hydrogen is passed over the cobalt oxide to reduce it to metallic cobalt. The apparatus is then allowed to cool to 150°–170° C., carbon monoxide is slowly passed through at a pressure of 100–120 atmospheres, and the issuing vapour is cooled to 0° C., whereupon crystalline cobalt carbonyl condenses. Pure metallic cobalt, massive or in the form of plates, is obtained by heating cobalt carbonyl vapour to a suitable temperature.—O. R.

Ores, shale, coal, and the like, more especially iron ores and iron-stone shale; Apparatus for use in subjecting — to the action of heat. J. B. Peat, Redcar, Yorks. Eng. Pat. 17,054, Aug. 13, 1908.

The apparatus is primarily intended for the treatment of iron ores and iron-stone shale by heat, in the absence of air. The lower oxide which results is magnetic and can afterwards be separated by magnetic separation. The ore is fed into a bunker, where it is dried by the heated products of combustion arising from the furnace. Any moisture condensing on the walls is collected and run off through a gutter. The ore discharged from the bunker is carried down an inclined way into a hopper which, under ordinary conditions, is fitted with a removable cover and so rendered gas-tight. From there it is directed by inclined pieces into a series of vertical tubes projecting downwards towards a shoot, where the ore is finally collected and removed through an opening in the bottom. These tubes are heated by the products of combustion of an exterior furnace connected with the apparatus by horizontal flues. To this end, each tube is surrounded by one of greater diameter, so that the hot gases, passing up through the annular space, are carried off and utilised in the manner previously described. Down the whole length of the interior tubes, vertical rods are passed, each of these rods being fitted at the lower end with a cone-shaped disc corrugated on the upper face. By the rotation of these rods a steady passage of the ore into and out of the tubes is assured, and clogging is avoided. The tubes are arranged so as to allow for any expansion in length, their lower ends being capable of moving up and down in stuffing-boxes of fire-clay. The heating effect of the system may be materially increased by collecting the small quantity of gas evolved in the reaction and blowing it in through the bottom of the furnace. If desired, these gases can be utilised in increasing the furnace draught.—C. A. W.

Subjecting materials [sulphide ores] to the action of air or other gases. J. E. Greenawalt, Denver, Colo. U.S. Pat. 921,645, May 11, 1909.

SULPHIDE ores are placed on a bed of porous materials in a furnace and heated, and air is forced upwards through the porous bed into the mass of ore.—W. H. C.

Refractory ores; Process of removing sulphur, arsenic, and other like impurities from —. F. Cotton, Hornsby, N.S.W., Australia. U.S. Pat. 922,088, May 18, 1909.

REFRACTORY ores are first heated and treated with hydrogen under slight pressure to remove sulphur. They are then treated with steam to convert the "base metals" into oxides, the volatile oxides formed being finally driven off by heating.—A. G. L.

Ore-treating furnace. C. C. Medbery, New York. U.S. Pat. 922,609, May 25, 1909.

The furnace is of the rotary kiln type, and comprises two oppositely inclined parts arranged one above the other, so that the upper or charging end of the furnace is immediately above the lower or discharging end. The furnace is provided with regenerators for heating the air and gaseous fuel. A receiving hearth for the molten minerals is arranged at the discharging end of the furnace, and is heated by the combustion products after these have first passed through one of the regenerators. A. T. L.

Separation of metals. R. D. Divine, Chicago, Ill. U.S. Pat. 921,372, May 11, 1909.

THE claim is for the process of separating the oxides of lead, antimony and zinc. The mixture of oxides is mixed with oil-cake and sodium carbonate and heated sufficiently to reduce the oxides to the metallic state and to volatilise the reduced zinc.—W. H. C.

[Steel] plate; Ballistic —, and method of treating armour or deck plates. S. S. Wales, Munhall, Pa., Assignor to Carnegie Steel Co., Pittsburg, Pa. U.S. Pats. 921,924 and 921,925, May 18, 1909.

BALLISTIC armour or vault steel plates are claimed, containing carbon, 0.20–0.35 per cent.; manganese, 0.25–0.35; nickel, 3.5–4.0; chromium, 1.25–1.75, and vanadium, less than 1 per cent. Or, nickel, less than 3.75, and vanadium, less than 1 per cent. Or, an unspecified quantity of nickel, besides chromium, less than 2, and vanadium, less than 1 per cent. Or, finally, nickel, 2.5–5.0 per cent., chromium, 1–2, and vanadium, less than 1. The steel plates are first given a fibrous structure by heat treatment, and are then hardened by heating them to above 875° C. and suddenly cooling them. The plates are finally annealed by heating to 350°–700° C. and cooling slowly.—A. G. L.

Ferro-nickel and nickel-steel; Process of making —. F. R. Carpenter, Denver, Colo. U.S. Pat. 922,388, May 18, 1909.

COPPER-NICKEL-IRON sulphide ores are given an oxidising roasting to oxidise nickel and iron, and then a chloridising roasting to render the copper soluble in water. After leaching out the copper, the residue, which is in the form of "blue billy" or "purple iron ore," and which contains practically all the nickel of the ore and little or no copper, is smelted to ferro-nickel or nickel-steel.—A. G. L.

Copper ores; Process for the lixiviation of —. O. Frölich. Ger. Pat. 209,324, Jan. 29, 1908.

IN processes for the lixiviation of copper ores, where rapid circulation of the liquor is effected by means of a pipe, with open ends, in which a screw rotates (see Ger. Pat. 163,409; this J., 1906, 379), or by Siemens' method of blowing in air at the bottom of a pipe with open ends, it is customary to use finely-divided ore. According to the present patent, the ore is used in relatively large lumps, so that only the liquor is circulated instead of liquor and ore-slime as when finely-divided ore is employed.—A. S.

Voltaic arcs; Process for producing long — Centralstelle für Wissenschaftlich-Technische Untersuchungen Ges.m.b.H., Berlin. Eng. Pat. 2216, Jan. 29, 1909. Under Int. Conv., Feb. 1, 1908.

THE process relates to a method of forming steadily burning long voltaic arcs, without the assistance of magnetic or other blowing. Air is introduced into an air chamber, and passes from the latter into the reaction vessel, which encloses the arc, through a number of perforations or through the pores of the vessel, in order to secure a uniform distribution of the gas.—B. N.

Furnaces; Electric — A. Voelker, Bonn, Germany. Eng. Pat. 28,276, Dec. 28, 1908.

THE furnace is provided with two electrodes, *d* and *e*, through the middle of which pass two adjustable prismatic poles, *h* and *i*. A prismatic electric connection, *m*, of smaller cross-section, is adapted to slide in prismatic cavities in the poles, in order to vary the effective heating length of the connection, and at the same time prevent the formation of an arc between the poles. In a modified form, the heating connection is made stationary by placing it on the bottom of the furnace, and the prismatic poles are made to slide on the connection. In a third form, the poles are placed vertically, the upper one being fixed, whilst the lower is movable and directly attached to the heating connection. The lower pole normally closes the

bottom of the furnace, but may be lowered for permitting the electric connection to engage in the plastic mass in the furnace.—B. N.

Cell for electrolytic or other purposes. H. S. Blackmore, Mount Vernon, N.Y. U.S. Pat. 922,079, May 18, 1909.

THE receptacle, used as the cell, contains an electrode, composed of a metallic carbide or acetylide and a binder, together with an opposite electrode and a body of electrolyte.—B. N.

PATENTS.

Ores [electrically]; Process of reducing — F. J. Tone, Niagara Falls, N.J. U.S. Pat. 921,183, May 11, 1909.

REFRACTORY ores, or compounds of elements, which at the temperature of reduction are subject to losses by volatilisation, are mixed with a reducing agent, and heated to a reducing temperature within the reaction zone of an electric arc furnace. The maximum temperature of the charge is kept at a point which practically prevents loss by volatilisation. The products are removed, as they are formed, by causing them to descend out of the reaction zone along an electrically heated resistance conductor, the upper end of which constitutes the lower electrode of the furnace, and the fused products are collected in a lower receiving space.—B. N.

Nickel ores; Process of treating — A. G. Betts, Troy, N.Y. U.S. Pat. 923,005, May 25, 1909.

THE ore is smelted so as to obtain an alloy containing nickel, copper, and a considerable proportion of iron. This alloy is refined electrolytically, using as electrolyte a solution containing both iron and nickel salts. A cathode deposit is obtained consisting of 3 parts of iron and 1 part of nickel, and copper or other metals are recovered from the anode slime.—A. T. L.

Furnace; Electric smelting — C. E. Wilson, Hood River, Oreg. U.S. Pat. 921,325, May 11, 1909.

THE furnace comprises a melting receptacle or crucible, the inner walls of which slant inwards toward the bottom. On the top of the melting receptacle is placed a water-cooled jacket or cover, having suitable openings formed therein. A screw conveyor leads to one of the openings, and a hopper, in which the material is placed, is secured above the screw conveyor. Tubes are arranged over a number of the openings, and a valve over one of them, a second set of tubes, slightly larger than the first, being arranged to slide up and down upon the outside of the first named. Electrodes pass through the tubes into the receptacle or crucible, rings being clamped to the upper ends of the electrodes and the rings clamped to the outer tubes. By means of a movable carriage, chains secured to the carriage and eyes formed with or secured to the rings, the electrodes may be moved up or down, or entirely removed from the receptacle or crucible. An open-hearth furnace is placed above the crucible at one side,

and a shoot leads from the furnace to the valve for conveying steel from the open-hearth furnace to the receptacle or crucible.—B. N.

Tin or allied metals: Electrolytically coating with—
J. C. Beneker, Waukegan, Ill., Assignor to The Meaker Co., Chicago, Ill. U.S. Pat. 921,043, May 18, 1909.

The solution employed contains approximately 25 parts of sodium hydroxide, 15 parts of sodium thiosulphate, 10 parts of stannous chloride, and 200 parts of water.
B. N.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

Mixed glycerides: Occurrence of—*in natural fats.*
J. Klimont and E. Meisels. Monatsh. Chem., 1909, 30, 341-346.

The fats examined by the authors were those of the domestic goose and turkey. The goose-fat had a sp. gr. of 0.9270 at 15° C., a saponification value of 193.3, and an iodine value of 70.1. On repeated recrystallisation from a mixture of acetone with a little chloroform, it yielded a crystalline powder (m. pt. 59° C.), which resembled tristearin and tripalmitin in appearance. The liberated fatty acids melted at a little above 55° C., and had a neutralisation value of 209.3. They consisted of stearic and palmitic acids in a proportion corresponding to 1 mol. of the former to 2 mols. of the latter (theoretical neutralisation value 210.4). The authors regard the fat as dipalmitostearin. The turkey-fat, examined in the same way, was a soft, granular, pale yellow fat with the following analytical characteristics: Sp. gr. at 15° C., 0.912; m. pt. 27 to 28° C.; saponification value, 193.6; and iodine value, 71.7. By repeated recrystallisation from a mixture of acetone with a little chloroform, a substance showing a constant m. pt. of 59 to 60° C. was obtained. From the mother liquor an oil with properties coinciding with those of triolein, was isolated. The substance of m. pt. 59 to 60° C. had a saponification value of 203.9, and contained fatty acids melting at 54 to 55° C., and having a neutralisation value of 209.7. The authors regard this fat also as a dipalmitostearin. Hansen (this J., 1902, 553) isolated a similar mixed glyceride melting at 55° C. from beef-fat, whilst Guth (this J., 1903, 427) prepared two dipalmitostearins synthetically. The authors suggest that the mixed glycerides isolated by them from these fats may be identical with one or both of the synthetical preparations. In experiments to determine whether mixtures of triglycerides could be obtained with constant m. pts., the authors purified synthetical tristearin and tripalmitin by repeated recrystallisation until they melted at 71° C. and 65° C. respectively. The pure triglycerides were then melted together in equal proportions, and recrystallised from acetone. The first crystals melted at 60° to 61° C., and on further crystallisation their m. pt. was gradually raised to 66° C., which was the highest point that could be reached. This product had a saponification value of 194.1, corresponding to a mixture of about 70 per cent. of tristearin and 30 per cent. of tripalmitin.

These results showed that the products obtained from goose-fat and turkey-fat were not mixtures of tristearin and tripalmitin, but definite compounds. The experiment also corroborates the statement frequently made that from natural fats containing both tristearin and tripalmitin it is impossible to isolate a pure tristearin by crystallisation (cp. also this J., 1909, 182).—C. A. M.

Porpoise oil. F. Hart. Chem.-Zeit., 1908, 32, 819.

Like most cetacean oils, porpoise oil from *Dolphina phocaena* is yellowish and has a fishy odour. It has the following characters:—Sp. gr., 0.9302 at 15° C.; increase of temperature by Maumene's test, from 25° to 86° C. free fatty acids, in terms of oleic acid, 1.39 per cent. iodine value (Hübl), 109.3; saponification value, 222.2 (Hehner value, 91.04; saponification value of insoluble fatty acids, 203. At the normal temperature, the insoluble fatty acids are semi-fluid. On adding a few drops of strong sulphuric acid to a solution of the oil in chloroform a pale violet blue colour is produced, changing to dark red. On adding strong hydrochloric acid to the oil, pale pink colour is given, passing to dull orange-yellow.
—J. O. B.

Petroselinic acid: a new oleic acid. E. Vongerichten and A. Köhler. Ber., 1909, 42, 1638—1639.

Oil obtained from parsley seeds yielded a deposit of needle-shaped crystals on crystallisation from a mixture of alcohol and ether. These crystals melted at 32° C. solidified at 16.5° C., and had a refractive index of 1.461 at 40° C., a saponification value of 191.2, and an iodine value of 84.3. In these values and in elementary composition they agreed closely with the theoretical figures for olein. On saponification they yielded a fatty acid which the authors termed *petroselinic acid*. It gave the following analytical values:—M. pt., 33°—34° C.; solidification point, 27° C.; sp. gr. at 40° C., 0.8681; refractive index at 40° C., 1.4533. Its elementary composition agreed with the formula, $C_{17}H_{33}O_2$, and it was thus isomeric with oleic acid. It yielded an amid crystallising in white needles (m. pt. 76° C.). Its lead salt dissolved with difficulty in cold alcohol and ether, but was readily soluble in hot ether, and its barium salt crystallised in anhydrous needles. It gave an "elaidic" acid meltin at 48° C., a dibromide, which was a heavy oil readily soluble in alcohol and ether, and a "stearolic" acid meltin at 54° C. (m. pt. of ordinary stearolic acid, 48° C.). Oxidation with alkaline potassium permanganate it yielded a dihydroxystearic acid melting at 122° C. The "stearolic acid," examined by Barch's method, gave a ketonic acid (m. pt. 80° C.), and the oxime of this acid, decomposed by Beckmann's method, yielded lauric acid, undecylamine, and pimelic acid. From these results the author concludes that the double linkage comes between the twelfth and thirteenth carbon atoms, and that the new acid has the structural formula, $CH_3.(CH_2)_{10}.CH:CH.(CH_2)_4.COOH$.

PATENTS.

grease, and other substances; Filters for —. G. G. Scurfield, Carlisle. Eng. Pat. 8228, Apr. 18, 1908.

filtration of the oil, etc., is accelerated by a preliminary treatment with steam. In the special method claimed, the steam is generated in, or admitted into, the receiving chamber below the filter-bed. Part of it is made to pass through the filter-bed and thus heat the unfiltered oil, whilst the remainder is condensed in the receiving chamber and creates a partial vacuum. The filter-bed is constructed of one or more plates perforated with holes enlarged on the side on which the filtering medium (felt, flannel, etc.) rests. To facilitate leaning, the bottom plate of the filter-bed is made to rest upon a loose S-shaped support, the upper perforated plate being fixed by means of screws, etc.—C. A. M.

Process of separating — from other liquids, and apparatus therefor. F. Nowotny, Bernburg, Germany. Eng. Pat. 24,237, Nov. 11, 1908.

The mixture is cooled to the temperature at which it requires its greatest density, so that the oil is expelled by the contraction, without the necessity of suction. In the type of apparatus claimed for carrying out this process, the liquid is passed through a vessel divided by partitions into a series of communicating chambers and cooled by means of a cooling liquid circulating in the opposite direction through a system of pipes in the vessel. Intermediate partitions separating the chambers are clear of the bottom so that the liquid can pass underneath, whilst the other partitions are provided with siphon tubes near the top. In separating oil from water of condensation, it is essential to prevent the entrance of steam under pressure into the separating chambers. For this purpose the liquid may be first passed into a cooling chamber the communication between which and the separating vessel is controlled by means of a valve and out.—C. A. M.

Apparatus for use in manufacturing —. A. J. Boulton, London. From E. Fischer, Dresden, Germany. Eng. Pat. 23,698, Nov. 5, 1908.

This apparatus, intended to reduce the time of boiling in the manufacture of rosin soap in solid form, consists of a vessel divided by a horizontal partition into a boiling chamber and an overflow chamber above it for the froth. The two chambers are connected in such a way that the cooled froth is conducted, without interruption, round the whole of the boiling chamber. By constructing the overflow chamber with corrugated walls the cooling surface may be increased and the return flow of the oil accelerated, notwithstanding the simultaneous heating of the material.—C. A. M.

Sodium peroxide composition for washing and bleaching purposes; Process for producing —. Firm of F. Gruner, Esslingen, Germany. Eng. Pat. 1150, Jan. 16, 1909. Under Int. Conv., Feb. 28, 1908.

THE sodium peroxide is made into a paste with a non-combustible chlorine substitution product of the paraffin series, such as carbon tetrachloride. Advantages claimed for this preparation are that it sinks in water, and is slowly and uniformly decomposed, and does not, when brought in contact with linen or other organic substances, tend to produce combustion. The carbon tetrachloride also assists in the detergent action. The action of the free alkali formed in the decomposition with water may be more or less neutralised by adding to the paste sodium bicarbonate, boric acid, or the like.—C. A. M.

(A.)—PIGMENTS, PAINTS.

PATENTS.

Paint and varnish removers. J. M. Wilson, Montclair, N.J., and H. A. Harris, New York, U.S.A. Eng. Pat. 10,043, May 8, 1908.

CLAIM is made for a paint remover which dries very slowly and on evaporation leaves soft but tenacious films with

little affinity for underlying surfaces. It is obtained by mixing together wax or a solid hydrocarbon or hydrocarbons, with a solvent, e.g., alcohol, preferably methyl alcohol, that will remove dried films of linseed oil and shellac, and a thickening agent (other than wax) such as "various oxy-compounds" of cellulose (nitrocelluloses, acetylcelluloses, etc.). Or the mixture may contain phenol, which promotes the formation of the soft tenacious film, and the beeswax and paraffin wax omitted or added in small proportion as desired. A preparation for which special claim is made consists of approximately 20 to 30 parts of methyl alcohol, 3 to 5 parts of colloid mixture (say, 92.5 per cent. of solvent, with 7.5 per cent. of nitrocellulose), 1.5 to 2.5 parts of phenol, and 1 part each of beeswax and paraffin wax.—C. A. M.

Sublimed white lead; Method of manufacturing—L. S. Hughes, Joplin, Mo., U.S.A. Eng. Pat. 16,520, Aug. 5, 1908.

SEE FR. Pat. 392,990 of 1908; this J., 1909, 98.—T. F. B.

(B).—RESINS, VARNISHES.

Pwé-nyet (black wax of Burma) and certain Indian dammars, D. Hooper, Agric. Ledger, 1908—1909, [3], 31—50.

THE wax is obtained from the nests of a stingless Indian dammar bee, *Trigona laeviceps*, and possibly other dammar bees. The best quality from Moulmein is a light yellow mass wrapped in leaves. It melts between 70° and 80° C., and is only partially soluble in the usual organic solvents. The specimen examined had the following characters:—Moisture, 3.2 per cent.; ash, 0.3 per cent.; soluble in alcohol, 86.2 per cent.; in ether, 72.2 per cent.; in light petroleum spirit, 79.3 per cent.; acid value, 28.3; ester value, 23.9; iodine value, 137.1. The portion soluble in alcohol is an amber-coloured resin, m. pt. 90°—100° C.; the part insoluble in alcohol and other volatile solvents is white and brittle, m. pt. 190°—200° C. The soft resin contains some fragrant volatile oil; it gradually loses this, becoming less aromatic and brittle. Inferior samples give results differing somewhat from the above. In order to trace the botanical source of the material, the dammar resins of several typical *Dipterocarpaceæ* and of a *Canarium* have been examined. The results are thus expressed:—

Kind of dammar.	Solubility in alcohol.	Acid value.	Ester value.	Iodine value.
	Per cent.			
<i>Dipterocarpus</i> resin	96.2	16.0	29.0	117.7
<i>Hopsea</i> "	74.4	33.3	34.8	92.3
<i>Vateria</i> "	57.3	35.4	46.1	62.2
<i>Shorea</i> "	56.0	38.8	81.0	52.5
<i>Canarium</i>	17.4	7.1	36.5	44.0

Pwé-nyet appears therefore to occupy a position between *Dipterocarpus* and *Hopsea* resins. Among the *Dipterocarpaceæ* resins, the iodine value decreases with the solubility, while the acid and ester values increase.—I. O. B.

PATENTS.

Resin and turpentine; Process of extracting—G. Walker, New York, Assignor to H. T. Varyan, Toledo, Ohio, U.S.A. U.S. Pat. 922,369, May 18, 1909.

TURPENTINE and other volatile substances are first distilled from the wood at a temperature insufficient to injure the resin, e.g., by means of a current of steam under reduced pressure at a temperature below the boiling point of turpentine. The residual wood is then dried, and the resin extracted from it by means of a neutral volatile solvent. Special claim is made for the use of neutral distillates of low boiling point from "hard-wood" tar as solvents for this purpose.—C. A. M.

Shellac substitute; Process for the preparation of a—J. J. Bischoff, Ger. Pat. 209,217, May 20, 1906. Addition to Ger. Pat. 206,447, May 8, 1906.

INSTEAD of oleine as mentioned in the main patent (th J., 1909, 251), other fatty acids, animal or vegetable oil fats, or waxes, or mineral oils, soluble in alcohol, may be added to alcoholic solutions of copal resins for the production of shellac substitutes.—A. S.

(C).—INDIA-RUBBER, &c.

Rubber of Sapim Jemmani from British Guiana, Bull. Imp. Inst., 1909, 7, 1—7.

TWO series of samples were examined. *Series A* consists of six samples from six different trees, growing on Fo Island and on the Lower Essequibo River, and a seventh sample obtained from trees in the Pomeroon district. The first six samples were received in the form of biscuits and of scrap (lace rubber). The seventh sample was in ball form. All the samples were inclined to be weak, tearing easily when stretched. The analytical results obtained together with a commercial valuation (Fine Para, 3s. 5½ per lb.), are given in the following table:—

	No. 1.	No. 5.	No. 6.	No. 7.
	Per cent.	Per cent.	Per cent.	Per cent.
Moisture	2.3	1.7	6.8	19.2
Dry rubber—				
Caoutchouc	87.1	87.9	89.8	89.3
Resins	2.8	3.6	3.7	4.2
Protein	5.8	4.0	4.9	2.5
Insoluble impurity	4.3	3.6	1.0	4.0
Ash	1.38	0.82	1.99	1.18
Value of scrap, per lb.	2s. 10d.	2s. 8d.	3s.	—
Value of biscuits or ball, per lb.		3s. 6d.		2s. 6d.

Note.—Nos. 2, 3, and 4 were not analysed, but were valued 2s. 8d. per lb. in the form of scrap, and 3s. 6d. per lb. in the form of biscuits or ball.

Series B consisted of samples from the N.W. district, British Guiana, and comprised:—(1) Three blocks scrap rubber, (2) two balls of rubber, (3) eight samples scrap. Analytical values, and commercial valuation are given in the following table:—

	No. 1.	No. 2.	No. 3.
	Per cent.	Per cent.	Per cent.
Moisture	2.6	8.4	1.1
Dry rubber—			
Caoutchouc	89.6	88.0	92.4
Resins	2.5	2.6	2.0
Protein	4.5	4.6	2.8
Insoluble impurity	3.4	4.8	2.7
Ash	1.26	1.13	0.69
Commercial value per lb. ..	2s. 4½d.	2s. 5d.	2s. 4½d.

A sample of rubber from the same species, exhibited at Olympia in September, 1908, was found to be much superior in physical properties to the above samples, and the analytical figures obtained were also better, viz.:—Moisture, 0.7; caoutchouc (in dry rubber), 94.4; resin 1.8; protein, 3.2; and ash, 0.6 per cent. This sample was valued at 4s. 3d., fine Para being 4s. 3½d.

These results indicate that the rubber of *S. Jenmani* should, if carefully prepared, realise satisfactory prices on the market. In tapping experiments it was found the nine trees averaging 57.6" in girth, tapped four times within 16 days, gave an average yield of 8.33 oz. of dry rubber per tree. The latex of *S. pauciflorum*, Hemsl., is said to be of no commercial value.—E. W. L.

Balata from British Guiana, Bull. Imp. Inst., 1909, 7, 7—8.

A SAMPLE of balata, from *Mimusops balata*, of guaranteed purity, was found to have the following composition:—Moisture, 1.9; gutta, 49.7; resins, 44.0; protein, 3.8; and ash, 0.6 per cent. The sample was valued at 2s. 2½d.

in London. The latex of the "Bastard Bullet" tree yielded, when coagulated by dilution and addition of alcohol, a pink, brittle, resinous substance, which on analysis was found to contain:—Resins, 70.6; and ash, 6.7 per cent., the residue being a white, friable powder quite unlike the gutta of true balata. This latex should therefore not be mixed with true balata latex.—E. W. L.

PATENTS.

India-rubber compound, and process of manufacturing same. F. G. d'Almeida, Rio de Janeiro. Eng. Pat. 11,949, June 2, 1908. Under Int. Conv., Jan. 28, 1908.

INDIA-RUBBER is dissolved in heavy tar oil, and the solution mixed with the other ingredients enumerated, in the following proportions:—India-rubber, 100; commercial brimstone, 36; heavy tar oil, 27; Portland or other suitable cement, 21; potash or rectified soda, 2; and sand, stone dust, and the like, $1\frac{1}{2}$ parts. The mixture is passed between rollers heated to 90° C., in order to render it perfectly homogeneous and drive off the volatile products from the heavy tar oil, and is then formed into prisms or blocks of the required shape. These are subjected to a pressure of 180 to 300 tons per sq. m., and are finally vulcanised by heating for from 5 to 8 hours at a temperature of 130° to 150° C. The composition is known as "vulcanina."—E. W. L.

Filling compositions intended for addition to rubber and other gums; Manufacture of —. Rütgerswerke Act.-Ges., Berlin. Eng. Pat. 14,859, July 13, 1908. Under Int. Conv., Oct. 11, 1907.

XIV.—TANNING, LEATHER, GLUE, SIZE.

Lactic acid in pine liquors; Formation of active —. W. Eitner. Gerber., 1909, 35, 127—128.

THE author has investigated this somewhat common phenomenon with a view to discovering the origin of the lactic acid fermentation, which produces abnormal swelling of the hides in the liquors, and a dark and horny leather. It is suggested that the ferment must originate either from the air or the water employed and the author has examined three waters used in a tannery where this trouble was experienced. One of these (the general supply for the tannery) was a spring water, whilst the other two were pond waters used when there was a scarcity of the spring water. This was generally in winter when the trouble was usually found to be more severe. Bacteriological examination of the waters showed that while the spring water and one of the pond waters were almost free from injurious ferments, the other pond water contained a large number of lactic acid-producing micro-organisms. A pure culture of this micro-organism introduced on to fresh pine-bark, produced fermentation in a few days, in a cool room. It is stated that the action is more severe at low temperatures, and that warming decreases the rate of fermentation.—S. H.

Tannin of the bark of Eucalyptus occidentalis [mallet bark]. J. Dekker. Arch. néerland. sc. exact. et nat., 1909, [2], 14, 50—80. Chem. Zentr., 1909, 1, 1707—1708.

By extracting the finely powdered bark of *Eucalyptus occidentalis* with 96 per cent. alcohol, a light brown substance is obtained, from which by dissolving in absolute alcohol and fractionally precipitating with ether, mallet-tannin can be isolated (see this J., 1905, 743). It is a brown, non-hygroscopic powder, easily soluble in water and methyl and ethyl alcohols, forming colloidal solutions; slightly soluble in acetone and ethyl acetate, insoluble

in ether, benzene, petroleum ether, and saturated sodium chloride solution. It has the composition, $(C_{19}H_{20}O)_n$, and yields an acetyl derivative, $C_{38}H_{28}O_{17}(C_2H_3O)_{10}$, and a benzoyl derivative, $C_{19}H_{15}O_{12}(COOC_6H_5)_5$. A 1 per cent. solution reduces silver nitrate solution and Fehling's solution on boiling, and gives a voluminous brown precipitate with a 0.5 per cent. solution of gelatin; with ammonia and with sodium hydroxide, a red coloration is produced. By boiling with 2 per cent. hydrochloric acid, mallet-tannin is converted into malletto-red, $C_{37}H_{30}O_{22}$, small quantities of gallic acid being also formed. Malletto-red is an amorphous cinnabar-red powder, insoluble in water and benzene, and slightly soluble in ether. It yields an acetyl-derivative, $C_{37}H_{35}O_{22}(C_2H_3O)_{15}$, and when distilled with zinc dust gives small quantities of a crystalline substance, probably diphenyl, melting at 70° C. Malletto-tannin yields small quantities of gallic acid and phloroglucinol when heated with zinc dust and sodium hydroxide; and pyrogallol and other phenols on destructive distillation.—A. S.

Tannin; The composition of —. L. F. Iljin. Ber., 1909, 42, 1731—1735.

THE author has prepared tannin white and free from ash by employing the methods of purification proposed by Walden (this J., 1899, 181), and by Rosenheim and Schidrowitz (Chem. Soc. Trans., 1898, 73, 882), and also by fractionally precipitating commercial tannin by sodium chloride from its aqueous solution or by chloroform from its solution in a mixture of alcohol, ethyl acetate, and ether. The purity was gauged by the rotatory power, the highest value obtained being $+76.5^{\circ}$. From the analyses of the various samples the author draws the conclusion that none of them corresponds with digallic acid which Nierenstein (Ber., 1908, 41, 78, 3015) considers to be identical with tannin. Tannin gives compounds with phenylhydrazine which are being examined.—J. C. C.

PATENTS.

Material of the nature of leather, and manufacturing same from hides. D. Reddan, Fitzroy, Victoria, Australia. Eng. Pat. 10,201, May 11, 1908.

THE hair of the hide is removed by the action of a solution of lime, and the hide is then well fleshed, rinsed in cold water and placed in a bath of dilute caustic soda and soft soap. It is subsequently worked, on a fleshing barrel, in a warm solution of alum, arsenic, soft soap and caustic soda, and is left in this solution for about four hours. After this treatment the hide is rinsed in cold water, dried, and then dressed with a soft rubber dough of the following composition:—India-rubber, 1 lb.; reclaimed rubber, 1 lb.; "Atmold" (infusorial earth), 2 oz.; "Nantusi" (a mixture of about 30 per cent. by weight of powdered sulphur, with about 70 per cent. of paraffin wax and a quantity of bees' wax and tallow), 4 oz.; "hypo carbon-black," 8 oz.; and "Vulcanine" (a mixture of sulphur and litharge), 8 oz. The atmold is said to act as a preservative against the action of heat, moisture, and oxidation. "Nantusi" is designed to prevent cracking under the influence of the sun. The rubber dough is worked into the hide by passing the coated hide between calender rolls, revolving at unequal speeds, a thin coating of the rubber being left on the surface of the hide, which is afterwards submitted to a temperature corresponding to 40 lb. pressure of steam for 10 minutes or more, either between the plates of a press, or wrapped between layers of canvas round a drum. In the latter case the drum and wrappings are covered with a steam and waterproof oilcloth. An alternative composition for the rubber dough may be employed, viz., reclaimed rubber, 2 lb.; sulphur, 8 oz.; zinc oxide, 7 oz.; lampblack, 1 oz.; and the following baths may be used for colouring the hide before calendering:—*Dark brown bath*: potassium permanganate, 1 lb.; eosin, 4 oz.; water, 2 galls. *Light tan bath*: copper sulphate, 2 lb.; water, 2 galls. *White bath*: arsenic, 1 lb.; potassium cyanide, $1\frac{1}{2}$ lb.; water, $1\frac{1}{2}$ to 2 galls. *Red bath*: eosin, $1\frac{1}{2}$ lb.; potassium permanganate, 4 oz.; water, 2 galls. *Black bath*: copper sulphate, 1 lb.; water, 2 galls.—E. W. L.

Leather product and process of making same. H. Mackay, El Paso, Texas. Eng. Pat. 2504, Feb. 2, 1909.

ORDINARY sole leather is soaked in water until it becomes thoroughly pliant, then allowed to become semi-dry, and is next given a coating of boiled linseed oil, the oil being applied upon the grain side only of the leather. The leather is then immersed in a liquid prepared by mixing 8 oz. of Portland cement and 2 oz. of bonax with sufficient water to make the consistence of the liquid equal to that of milk. When this mixture has permeated the pores of the leather (this takes 24 hours, or more), the latter is removed from the bath, dried, a coating of linseed oil is applied on both sides, and when the oil has dried, the leather is rolled and "finished." It is claimed that the treatment considerably increases the durability of the leather.—W. P. S.

Compound of proteids and amines; Thermoplastic —. B. B. Goldsmith, New York. U.S. Pat. 922,133, May 18, 1909.

THE claims are for a process consisting in the addition of an amino-compound, such as naphthylamine, to an albuminoid, and the subsequent heating and compressing of the mixture, and for the thermoplastic compound thus produced.—E. W. L.

Hide-tanning machine; Automatic —. C. J. Glasel, South Boston, Mass., Assignor to L. Behre, Hanover, Germany. U.S. Pat. 922,415, May 18, 1909.

XV.—MANURES, &c.

Chili saltpetre, calcium saltpetre (calcium nitrate) and nitrolime (crude calcium cyanamide); Comparison of the manurial value of — for the sugar beet. J. Urban. Z. Zuckerind. Böhm., 1909, 33, 535—547.

THE experiments have been carried out during two years. The manurial value of nitrolime for the beet is satisfactory, especially in years of abundant rainfall, but is not equivalent to that of Chili saltpetre. In 1906, a wet year, its value was expressed as 85.6 per cent. of that of Chili saltpetre, whereas in 1907 it was only equivalent to 75 per cent. of Chili saltpetre. The effect on the sugar content of the beet was not marked; in 1906 this was 0.35 per cent. higher, in 1907 0.18 per cent. lower than in beets manured with Chili saltpetre. It is necessary to apply nitrolime a week or more before the seeds are sown. An adverse property of nitrolime is the difficulty of distributing it by hand. Calcium saltpetre was found in 1907 to have a manurial value slightly higher than that of Chili saltpetre (111:100), and the beets contained on the average 0.16 per cent. more sugar. Nitrogenous manures lower the percentage of sugar when the soil has no lack of nitrogenous constituents, but markedly increase it when the soil is deficient therein.—E. F. A.

Ammoniacal manures; Action of —. P. Ehrenberg, Landw. Versuchstat., 1908, 69, 259; Biedermann's Centr., 1909, 38, 302—303.

As the result of his experiments, the author is of the opinion that the assimilation of nitrogen by plants from ammoniacal manures is governed chiefly by the acid reaction of the soil, this acidity increasing as the plant takes up nitrogen from the ammonium salt owing to the liberation of the acid radical of the salt. The addition of calcium carbonate to neutralise the natural acidity of the soil is not sufficient to yield a good crop, especially in the case of plants which do not grow well on acid soils, as the continual formation of acid as the plant absorbs nitrogen tends to inhibit the growth of the plant.—W. P. S.

Lime and magnesia; Influence of the relative proportions of — on the growth of plants. L. Bernardini and G. Corso, Staz. sperim. agrar. ital., 1908, 41, 191; Biedermann's Centr., 1909, 38, 304—305.

FROM the results of the experiments recorded, it is seen that the ratio of lime to magnesia in soils is of considerable

influence on the growth of plants. In the case of rye the best results are obtained when the ratio is as 1 to 1; for wheat, 2 to 1; and for beans, 3 to 1. These results were obtained by experiments on plants growing in nutrient solutions and in pots.—W. P. S.

Colloidal manganese oxide solutions; Action of — in biochemical oxidations. B. Sjöllema, Chem. Weekblad, 1909, 6, 287—294. Chem. Zentr., 1909, 1, 1718.

IF a solution of manganese sulphate or manganese acetate be treated with a solution of Rochelle salt, and then hydrogen peroxide and dilute sodium hydroxide solution added, a colloidal solution of manganese oxide is obtained, which retains its dark brown colour for several weeks. This solution, both before and after dialysis, gives the different reactions characteristic of oxydases, e.g., it produces a blue coloration with fresh guaiacum tincture and with a solution of *p*-phenylenediamine hydrochloride. A colloidal manganese solution produced by adding hydrogen peroxide to potassium permanganate and subjecting the product to dialysis against water, behaves in a similar manner. The manganese solution rapidly decomposes hydrogen peroxide, with effervescence, but hydriodic acid is not oxidised by it. The author suggests a closer investigation of biochemical oxidations, especially those occurring in plants, which contain considerable quantities of manganese; probably manganese plays an important part also in oxidations in soils.—A. S.

Nitrates from the atmosphere. Eyde. See VII.

PATENTS.

Phosphatic chalk; Treatment of —. J. Gathy. Fr. Pat. 396,358, Nov. 16, 1908. Under Int. Conv., Nov. 20, 1907.

THE ground phosphatic mineral is introduced into water in a suitable vessel and subjected to the action of an excess of sulphur dioxide, whereby calcium carbonate is converted first into sulphite, and finally into bisulphite, which is soluble in water. The insoluble residue, rich in phosphate, is then separated by filtration or decantation, and calcium sulphite is recovered from the solution by boiling under diminished pressure.—O. R.

Calcium cyanamide; Process of granulating powdered —. A. d'Ereole. Fr. Pat. 396,403, Nov. 17, 1908.

POWDERED calcium cyanamide is spread out over a convenient surface, rapidly and uniformly moistened with pure water, or with certain solutions, and finally quickly spread into very thin layers and agitated until it is perfectly dry. Suitable solutions are those of sodium, magnesium, manganese, zinc, iron, aluminium, and calcium salts in water. Instead of mineral salts, solutions of gum or gelatin, with or without the addition of alum or aluminates, may be employed.—O. R.

Fertilisers; Production of —. O. F. Carlson, Stockholm. Eng. Pat. 21,590, Oct. 12, 1908.

SEE Fr. Pat. 395,197 of 1908; this J., 1909, 320.—T. F. B.

XVI.—SUGAR, STARCH, GUM, &c.

Diffusion waste waters [Sugar]; Return of the —. C. Pfeiffer. Deutsche Zuckerind., 1909, 34, 437—438.

THE author advocates the separate return of the draining water and press water to the battery. In this method of working, the press water is pumped into the last diffuser whilst the battery is receiving a fresh charge; the amount of draining and fresh water subsequently pumped into this diffuser suffices to drive all the press water into the penultimate diffuser. Owing to the fact that no press water is left in the last diffuser, an accumulation of sugar, salts, and organic non-sugar in the waste water is avoided, and hence, the waste water can be returned to the battery continuously. Again, this method insures a more complete extraction of the sugar, since the water poorest in sugar (i.e., the mixture of draining and fresh water) comes in contact with the nearly exhausted slices in the last diffuser,

whilst the press water of higher sugar-content comes in contact with slices which have been less completely extracted. Moreover, the sugar obtained by this method of working is of high purity.—L. E.

Sugar; Adsorption of — by animal charcoal. R. O. Herzog. *Z. physiol. Chem.*, 1909, **60**, 79—84 (Compare this J., 1909, 535).

The experiments described in this paper were carried out in connection with an investigation on tanning processes (this J., 1908, 347). Purified blood charcoal was used as adsorbent, and preliminary experiments showed that (1), adsorption of dextrose is practically complete in half an hour; (2), the charcoal does not cause catalytic oxidation of the sugar; (3), a reversible equilibrium exists between the sugar adsorbed and that left in solution. From experiments in which 100 c.c. of solutions of various sugars of approximately $\frac{1}{2}$, $\frac{1}{4}$, and $\frac{1}{10}$ normal concentrations and 5 grms. of animal charcoal were used, the following values for the constants, k and n , of the equation $C = kB^n$ were deduced (C and B represent the amounts of sugar adsorbed and left in solution respectively).

Sugar	k .	n .
Dextrose	0.766	0.474
Lævulose	0.338	0.539
Galactose	0.916	0.694
Sucrose	0.106 (?)	0.127
Maltose	1.142	0.133
Lactose	1.138	0.135

It is noteworthy, that in the cases of the monoses, the values for k and n differ very considerably, whereas, with the bioses, they differ very little. Hence it is probable that in the case of bodies of relatively small molecular weight, the constitution is of prime importance in connection with adsorption; on the other hand, the experiments with the bioses appear to indicate that similarly constituted substances of high molecular weight present approximately coincident adsorption curves. Experiments were also made in which 3 grms. of charcoal and approximately $\frac{1}{4}$ -normal solutions of sugars were used. The results obtained agreed fairly well with those calculated from the equation $\frac{C}{m} = kB^n$, in which m represents the quantity of adsorbent. The results obtained also agreed fairly well with those calculated from an equation of Freundlich who found that with variable quantities of adsorbent (m), and constant quantities of (originally) dissolved substance, (A), and solutions of constant volume, the adsorbed quantity (C), can be calculated from the equation $\lambda = \frac{1}{m} \log \frac{A}{A-C}$, in which λ is a constant.

—L. E.

Sugars; Compounds of benzidine with — and a method for isolating lævulose. O. Adler. *Ber.*, 1909, **42**, 1742—1746.

The author describes the preparation and properties of didextrose-benzidide, diarabinose-benzidide, and dimaltose-benzidide. These compounds are obtained by heating benzidine with dextrose, arabinose, and maltose respectively, in solution in 96 per cent. alcohol. They reduce copper and bismuth salts on heating in alkaline solution; they are decomposed by sulphuric acid, benzidine being split off in the form of insoluble sulphate. Lævulose does not yield a crystalline substance with benzidine when treated as above described, and the benzidine reaction may therefore be utilised for removing dextrose from mixtures of this sugar and lævulose; to effect this separation the author adopted the following mode of procedure:—The alcoholic solution of the mixture of dextrose and lævulose was heated for 3 hours on the water-bath under a reflux condenser with a quantity of benzidine equivalent to the total quantity of sugar (1.8 parts of hexose correspond to 1.84 parts of benzidine). Two-thirds of the alcohol was then distilled off, and the residue was allowed to stand for 12 hours. The didextrose-benzidide which separated, was filtered off and washed

with a small quantity of absolute alcohol; the filtrate was concentrated as far as possible on the water-bath, and again allowed to stand for 12 hours. The substance which separated was filtered off and washed with a very small quantity of absolute alcohol. The filtrate was evaporated, the residue being taken up with a moderate quantity of water; the bulk of the excess of benzidine and any tar were thus precipitated. This precipitate was macerated with water in order to extract lævulose, filtered off under pressure and washed with water. The filtrate was treated with sufficient sulphuric acid to precipitate the benzidine still present, and to decompose any didextrose-benzidide remaining in solution; after standing for a short time, the solution was filtered, the filtrate thus obtained containing lævulose with only a slight admixture of dextrose. The process is applicable to urine, but in this case, an alcoholic extract of the urine, purified as far as possible, must be used.

—L. E.

Mannose, arabinose, xylose, and hydrolysed lactose; Determination of —. R. O. Herzog and F. Hörth. *Z. physiol. Chem.*, 1909, **60**, 152—154.

The authors have carried out determinations with the pure sugars according to Kjeldahl's proposals (*Z. anal. Chem.*, 1896, **35**, 344). 30 c.c. of Fehling's solution and 30 c.c. of the sugar solution were placed in an Erlenmeyer flask of about 150 c.c. capacity, and made up to exactly 100 c.c. with water. A current of hydrogen was then led through the solution, and the latter heated for exactly 20 minutes in a boiling water bath. The reduced cuprous oxide was collected on asbestos in a Soxhlet filter-tube, washed with hot water, alcohol, and ether, oxidised to cupric oxide in a current of air, and weighed. The experimental results for different concentrations of the sugars are given in four tables, and from them four other tables were constructed, of which the following is a combination:—

Weight of sugar.	Weight of copper.			
	Hydrolysed lactose.	Mannose.	Arabinose.	Xylose.
mgrms.	mgrms.	mgrms.	mgrms.	mgrms.
15	—	34.6	35.0	34.4
20	42.2	44.5	45.2	44.0
25	51.6	54.0	55.5	53.5
30	61.3	63.8	66.2	63.5
35	70.9	73.5	76.2	72.7
40	80.5	83.0	86.5	82.5
45	90.0	92.6	96.6	92.3
50	99.6	102.3	107.0	101.7
55	109.3	112.0	117.2	111.5
60	118.9	121.5	127.3	121.0
65	128.5	130.7	137.5	129.5
70	138.0	140.0	146.6	137.6
75	147.7	148.9	156.2	146.0
80	157.3	158.0	165.5	154.3
85	166.7	166.0	175.0	163.4
90	175.4	174.2	—	172.6
95	183.3	182.2	—	182.0
100	191.2	190.5	—	191.4
105	199.5	198.7	—	—

The lactose was hydrolysed by heating 50 c.c. of a 1 per cent. solution with 1 gram. of concentrated sulphuric acid for 4 hours on a boiling water bath, the evaporated water being occasionally replaced; the solution was then cooled, neutralised, and made up to 250 c.c.—A. S.

Manurial value of Chili saltpetre, calcium saltpetre, and nitrolime for the sugar beet. Urban. *See XV.*

XVII.—BREWING, WINES, SPIRITS, &c.

Maltases of maize; Influence of the reaction of the medium on the activity of the —. R. Hueie. *Compt. rend.*, 1909, **148**, 1121—1123.

It is known that the activity of enzymes depends very closely on the reaction of the medium, and that whilst maltase is most active in faintly acid media, it is completely paralysed by the presence of an organic acid

equivalent to 0.2 per cent. of sulphuric acid. The various maltases of different varieties of maize studied by the author (this J., 1909, 254, 431) behave differently in this respect, some showing their maximum activity in distinctly alkaline media, others acting best in neutral or very faintly acid media. This is another point in favour of the specific difference of the various maltases studied. The reaction of the medium has no influence on the temperature relationships of the various maltases. These temperature relationships, which serve for the classification of the maltases, have no connection with the behaviour of the enzymes towards basic or acid media. The maltases which show their maximum activity in media very slightly alkaline to methyl orange are those of the yellow maize of the Landes, "King Philipp" and "Auxonne." These maltases behave like the amylase of malt, but they are still capable of hydrolysing maltose when the reaction is distinctly acid. The optimum alkalinity for these varieties corresponds to 1 c.c. of *N* 10 acid per 100 c.c.; they are paralysed by acidities equal to 0.019–0.029 per cent. of sulphuric acid. The maltase of the early white maize of the Landes, shows a maximum activity when 1–3 drops of *N* 10 potassium hydroxide are added to 10 c.c. of the medium; the addition of acid is distinctly unfavourable. In the case of "Cuzco red" and "Cuzco white" maizes, on the other hand, the maximum activity is exerted when the natural alkalinity of the medium towards methyl orange is neutralised or even when 2–3 drops of *N* 10 acid per 10 c.c. are added in excess.

—J. F. B.

Bulgarian ferment (yoghourt); Action of — on various sugars. G. Bertrand and F. Duchéck. *Compt. rend.*, 1909, 148, 1338–1340.

THE Bulgarian ferment (yoghourt) when grown in milk hydrolyses lactose and converts the monosaccharides formed into a mixture of *d* and *l*-lactic acids, in which the former predominates. The action has now been studied on several sugars contained in a fluid consisting of malt extract to which has been added 1 per cent. of Chapoteau's peptone and 3 per cent. of calcium carbonate. This was sterilised at 120° C. and maintained at 32° C. with an active culture of the ferment. Yoghourt is totally without action on arabinose, xylose, sorbose, maltose, sucrose and mannitol, but attacks dextrose, mannose, levulose, galactose and lactose. The products are the same in each case; mainly *d* and *l*-lactic acids, a small proportion of volatile acids (formic and acetic acids) and some succinic acid. The mixture of lactic acids is inactive, however, and it is suggested that when grown in milk the organism, after the decomposition of the lactose, cause the *l*-lactic acid to disappear more rapidly than *d*-lactic acid, whereas in the artificial nutrient medium, it attacks malt peptone preferentially to lactic acid. The Bulgarian ferment contains neither invertase nor maltase.—E. F. A.

Ferment action; Influence of boric acid on —. H. Agulhon. *Compt. rend.*, 1909, 148, 1340–1342.

ENZYMES, with the single exception of that of the castor oil seed, have their action only very feebly affected by the presence of boric acid. Some enzymes are even rendered more active by certain proportions of the acid, and invertase in particular is most active in presence of a considerable quantity, but it is well known that the maximum activity of this enzyme is exercised in presence of acid. Boric acid is not a sufficiently strong acid to render pepsin active.—E. F. A.

Lager beers. J. Grant. *J. Inst. Brewing*, 1909, 15, 376–386.

LAGER beer, the name originally given to Bavarian beers, is now applied to most of the beers brewed by the decoction system and stored in the cold or lager cellars. In addition to the ordinary lager beers there are a number of others consumed on the Continent, the chief of which are:—"Schenk" or winter beers, decocted in winter, and rapidly fermented, for immediate consumption. They usually come into condition in 3–7 weeks, and being brewed from a very light-gravity wort, they are not very stable.

"Bock" beers formerly occupied a position intermediate between the "Schenk" and the ordinary lager beers but are now usually brewed of a higher gravity, 21–26 lb., for export trade. These are brewed for spring consumption and from an extra strong wort. The "White beers" vary greatly according to the locality; they are characterised by a very pale colour, decided acid flavour, and richness in gas which causes them to foam strongly. The well known Berlin "white beer" is brewed from two parts of wheat malt and one part of barley malt. The Belgian spontaneous fermentation beers are also of interest; they are brewed in three strengths from equal parts of barley malt and raw, crushed wheat; they are very dextrinous and take 2–5 years to come into proper condition. Of the true lager beers there are four recognised types. The Bavarian or Munich beers possess a light to dark-brown colour, they are lightly hopped and are characterised by their palateness, sweet taste and malt flavour. Their gravities range from 18.2 to 22 lb. for light beers and from 22 to 26.7 lb. for export beers. The Bohemian beers are light-yellow to greenish-yellow in colour. They taste somewhat sharp, dry and wine-like, with a prevailing bitter flavour of hops; their gravities range from 15.1 to 16.6 lb. for the light and from 16 to 18.6 lb. for the heavy. The Vienna lager beers come midway between the Bavarian and the Bohemian in colour, hop-flavour, and taste; their gravities vary from 15.1 to 19.7 lb. for the light and from 19.7 to 22.8 lb. for the heavy or export beers. Most of the common beer in Vienna is brewed at a gravity of 19.7 lb. The American lager beers generally follow the German rather than the Austrian type. The author describes the methods of mashing, the two-mash and the three-mash decoction systems, the methods of fermentation and cellaring. The beers are run into the lager casks containing a considerable quantity of fermentable extract; the temperature of the cellar ranges from 32° to 41° F. Some beers are treated with "Krausen" taken from normally fermenting beers, but this is never used when the beers are to be carbonated. The average composition of lager beers is given in the following table:—

	Water	Carbon dioxide.	Alcohol, by weight	Extract.	Acidity (as lactic acid).	Ash.
	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.
Ordinary lager ..	90.000	0.196	3.890	5.794	0.151	0.305
Carlsberg lager ..	90.000	0.193	4.270	5.286	0.149	0.309
Export lager ..	89.000	0.209	4.410	6.292	0.160	0.321

—J. F. B.

Grape musts; Variations in the proportion of dextrose and levulose in —. P. C. Mestre. *Ann. Chim. analyt.*, 1909, 14, 185–187.

RESULTS are given showing that whilst about equal quantities of levulose and dextrose are present in musts obtained from healthy, ripe grapes, the quantity of dextrose is always less than that of the levulose when the grapes have been attacked by insects or fungi. The ratio of the sugars to one another in such musts is similar to that in musts which have been partially fermented.—W. P. S.

Acetic aldehyde in wine; The action of — on some of the other constituents. A. Trillat. *Bull. Soc. Chim.*, 1909, 5, 546–555.

THE acetic aldehyde present in wine and brandy results from the oxidation of the alcohol under the influence of atmospheric oxygen; the aeration of the wine, the presence of micro-organisms, the age of the wine, etc., are factors which govern the quantity of aldehyde present. The free aldehyde which is formed disappears gradually; it combines with the colouring matters of the wine to form a more or less insoluble precipitate, and also combines with the alcohol to give acetals which in their turn are con-

verted into colouring matters. A portion of the aldehyde is also oxidised to acetic acid which forms esters contributing to the quality of the wine. The aldehyde and acetal also in course of time polymerise or are converted into bitter substances.—W. P. S.

Wine; The presence of inositol in — and its detection.
G. Perrin. Ann. Chim. analyt., 1909, 14, 182—183.

INOSITOL occurs in all natural wines and its presence may be used as a criterion for distinguishing between pure and artificial wines, the latter being free from this substance. It may be detected by treating 200 c.c. of the wine with basic lead acetate and a few drops of an alcoholic solution of tannin, filtering the mixture, removing the excess of lead from the filtrate by hydrogen sulphide, treating the filtrate from the lead sulphide with animal charcoal, and evaporating the clear liquid to a volume of about 10 c.c. Two drops of this liquid are then mixed on a piece of platinum foil with one drop of silver nitrate solution, evaporated to dryness, and the residue cautiously carbonised; a red coloration is produced if inositol be present. Or, a few drops of the concentrated liquid may be evaporated with a drop of nitric acid; after charring the residue, a drop of ammonia is added, and the evaporation repeated, when a red coloration appears.—W. P. S.

Citric acid fermentation by Citromyces. E. Buchner and H. Wüstenfeld. Biochem. Zeits., 1909, 17, 395—442. (Compare this J., 1909, 538.)

THE mechanism of the formation of citric acid from dextrose is of great theoretical interest, since, owing to its branched carbon chain, this acid cannot be formed from the sugar by a simple oxidation process. Comparative experiments with different *Citromyces* showed that *C. citricus* (original race) gives the highest yield of citric acid, and this organism was used in the subsequent experiments. The fermentations were carried out at the ordinary temperature. Apart from the sugar, a decoction of beans (white or green) was found to be the best nutrient medium from the point of view of citric acid formation. To obtain a high yield of citric acid, addition of calcium carbonate is indispensable, the nitrogen-content of the medium should be low, and the fermentation should be carried out in a shallow dish. By cultivating *C. citricus* in 100 c.c. of a decoction of white or green beans (containing 0.02 per cent. of nitrogen) to which 5 grms. of calcium carbonate and 6.5—12.8 per cent. of dextrose had been added, for 57—66 days, yields of citric acid, of 43—56 per cent. of the weight of sugar consumed, were obtained. Experiments in which a bean decoction containing 0.025 per cent. of nitrogen was used, showed that an abundant citric acid formation does not occur until most of the nitrogen has been assimilated; the residual nitrogen-content remains fairly constant owing to equilibrium between assimilation, on the one hand, and proteolysis of older portions of the hyphae, on the other. Besides citric acid, carbon dioxide is the only metabolic product formed in appreciable quantity; in absence of calcium carbonate, the proportion of carbon dioxide is increased at the expense of the citric acid. If fermentation, carried out at first under normal conditions, is subsequently continued *in vacuo*, small quantities of ethyl alcohol are formed. With regard to the mechanism of the citric acid formation, experiments showed that it is improbable that this acid is synthesised from oxalic and acetic acids, or that it is formed by decomposition from the protoplasm of the *Citromyces*. It may be that parasaccharinic acid or a derivative of this acid, or, broadly, a body closely related to the sugar group and perhaps related to the cell membrane carbohydrates of high molecular weight, is an intermediate product in the citric acid formation. Such a substance has not been detected, however; mannitol was the only reserve substance found in the *Citromyces*. Attempts to effect the citric acid fermentation with expressed juice, or with acetone permanent preparations of *C. citricus*, were unsuccessful. Since the formation of citric acid from sugar only involves a partial oxidation of the latter, the citric acid fermentation is not advantageous to the *Citromyces* from the point of view of energy production, and the acid is of little value as a protection against other organisms.

The citric acid formation is not a necessary accompaniment of the growth of the organism. From the fact that a considerable formation of citric acid does not occur until the nitrogen-content of the nutrient medium has been much reduced, it may be supposed that the *Citromyces*, weakened by deficient nitrogen nutrition, have lost the power of consuming citric acid rapidly and completely, or it may be that with deficient nitrogen nutrition, the organisms no longer possess those enzymes which effect the further oxidation of the citric acid.—L. E.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(A.)—FOODS.

Flour bleaching. H. Snyder. Univ. of Minnesota Agric. Exp. Stat., Bull., 1908 [111], 101—143. (See also this J., 1909, 377.)

THE bleaching of flour is a natural process and takes place when flour is stored in thoroughly ventilated warehouses; this bleaching is due to the action of light and air upon the colouring matter of flour which is an unstable organic compound mechanically associated, as an impurity, with the fat and gluten. With natural ageing and bleaching there is a slight improvement in bread-making value. The colouring matter of flour is also acted upon by a number of chemical reagents such as chlorine, sulphur dioxide, and traces of nitrogen peroxide, but none of the methods proposed for bleaching flour, except the use of minute amounts of nitrogen peroxide as generated by the discharge of electricity in the air, has survived the experimental stage. Air containing from four to eight parts of nitrogen peroxide per 100,000 parts will effectually bleach flour and there is left in the flour a quantity of nitrogen as nitrite-reacting material amounting to less than one part per million of flour. The fats from bleached and unbleached flour milled from the same wheat are identical as far as the iodine value, nitrogen content, and heat of combustion are concerned; the glens from the two flours are identical in physical properties, and show the same index of refraction. The nitrogen peroxide used in small amounts in the electrical bleaching of flour exerts no chemical action upon the flour other than upon the colouring matter; it appears to be a carrier of oxygen without itself entering into chemical combination with the flour. The nitrite-reacting material in flour seems to be in physical rather than chemical combination; when the flour is heated, the nitrite-reacting material imparted by bleaching is expelled. When the bleaching gas is brought into contact with sand, with which it cannot unite chemically, the same amounts of nitrites are absorbed as in the case of flour. In tests where different quantities of gas were used, it was found that the amount of nitrite-reacting material left in the flour increased with the amount of gas used up to a certain point, and that when a larger excess of the gas was employed, there was permanently retained in the flour no more than when less of the gas was used. Breads made from bleached and unbleached flours when baked in a badly ventilated gas oven contained the same amount of nitrites; when the breads were baked in an oven out of contact with the combustion gases, nitrites were absent. Bread cannot contain any appreciable amount of nitrite-reacting material as the carbon dioxide and organic acids produced during bread-making decompose nitrites. In fifteen digestion experiments with men, no difference was observed in the digestibility of breads from bleached and unbleached flours: the bleaching of the flour did not exert any influence on the amount of nutrients absorbed and digested. Artificial digestion experiments with pepsin solution gave similar results. Nitrites are produced as a result of the combustion of all fuels and organic substances containing nitrogen; flour exposed to wood smoke for a few minutes will contain more nitrites than when electrically bleached. Smoked bacon, ham, etc., contain larger amounts of nitrites than does bleached flour. A kerosene lamp will produce in one hour 0.00027 gm. of nitrite-nitrogen. Nitrites are present in air, rain-water, and many drinking

waters, and are found in vegetables such as celery, lettuce, and spinach; they are a normal constituent of saliva and, with nitrates, are often found in milk where the cows have been liberally fed on roots. In bread-making tests of commercially bleached flours, no difference was observed between the breads produced from the bleached and unbleached flours milled from the same wheats, except that the bleached flours produced a whiter bread and also showed a tendency to produce larger sized loaves.—W. P. S.

Milk; Determination of dirt in —. G. Fendler and O. Kuhn. Z. Unters. Nahr. Genussm., 1909, 17, 513—526.

In the process recommended, 100 c.c. of the milk are submitted to centrifugal action in a tube, the lower end of which is constricted. The dirt collects in this narrow portion of the tube, and, after the milk has been poured off, is treated with 15 c.c. of 10 per cent. ammonia; at the end of 30 minutes, water is added, and the contents of the tube are again submitted to centrifugal action. The sediment is then collected on a filter, washed successively with water, alcohol, and ether, dried at 100° C., and weighed. The authors consider that any milk which yields more than 1 mgrm. of sediment per 100 c.c. of milk is to be considered as being dirty.—W. P. S.

Cacao beans; The theobromine content of —. A. Kreutz. Z. Unters. Nahr. Genussm., 1909, 17, 526—528.

It is shown that about one-half of the theobromine present in cacao beans is in the free state and can be extracted directly by means of chloroform; the remainder is present in a combined form and only goes into solution in chloroform after the cacao has been subjected to hydrolysis (heating with dilute sulphuric acid). The fat is extracted together with the theobromine and the two may be separated by treatment with cold carbon tetrachloride (see this J., 1909, 215).—W. P. S.

Formic acid; Determination of — in fruit juices. F. Schwarz and O. Weber. Z. Untersuch. Nahr. Genussm., 1909, 17, 194—197.

From 25 to 50 grms. of the juice is distilled with steam under pressure until 250 c.c. of distillate have been obtained. This is titrated with *N*/10 sodium hydroxide solution, evaporated to dryness, and redissolved in water. This aqueous solution is then oxidised by boiling with an equal volume of a solution of 12 grms. of potassium bichromate, 30 c.c. of strong sulphuric acid, and 100 c.c. of water. After cooling, the mixture is again distilled, as before, and the distillate titrated. The difference between the two titrations gives the equivalent of formic acid, which has been destroyed by the oxidising mixture, whereas acetic acid is unaffected. A Kjeldahl flask with a long neck is most suitable for these distillations.—J. O. B.

Benzoic acid; Detection of — in alimentary products. A. Jonescu. J. Pharm. Chim., 1909, 29, 523—525.

The material is suspended in water, acidified with sulphuric acid, and distilled with steam. The distillate is shaken with ether, the ether extract is evaporated, and the residue taken up with warm water. To 1 c.c. of this aqueous solution, 1 drop of a 10 per cent. solution of 3 per cent. hydrogen peroxide and 1 drop of a solution of ferric chloride (1 part of solution of sp. gr. 1.280:9 of water) are added. The tube containing the mixture is then immersed in boiling water. In the presence of benzoic acid, which will have been converted into salicylic acid by the hydrogen peroxide, the characteristic violet colour-reaction will appear on the surface of the liquid. The tube is then withdrawn and allowed to cool. The absence of phenolic bodies and saccharin in the original material, must be ensured. The presence of 0.25 grm. of sodium benzoate in 500 c.c. of milk is readily detected by this method.—J. O. B.

Coking test. [Its proposed extension to the testing of foods, etc.] O. Bimler. Z. anal. Chem., 1909, 48, 372—375.

NON-VOLATILE organic substances, when heated in a covered platinum crucible, as in the "coking" of a sample of coal, yield definite amounts of coke, of more or less

characteristic appearance. Starch, for example, gives more than twice as much coke as dextrin, although these two substances have the same empirical formula. It is proposed, therefore, to utilise this property as furnishing an additional means of ascertaining the purity of foods and other organic materials.—F. SOPN.

Action of Bulgarian ferment (yoghourt) on various sugars. Bertrand and Duchéck. See XVII.

Sodium benzoate as preservative for foodstuffs; Use of —. Food Inspection Decision No. 104. U.S. Dept. of Agriculture.

In consequence of the report of the "Referee Board" (see this J., 1909, 215), no objection will be raised under the Food and Drugs Act to the use of sodium benzoate in food, providing that each package or container is plainly labelled to show the presence and amount of benzoate. Food Inspection Decisions 76 and 89 are amended accordingly.

PATENTS.

Aerated waters; Manufacture of —. A. J. Harries and R. W. C. Palmer, London. Eng. Pat. 6641, Dec. 15, 1908.

The waters are aerated under a high pressure, say 250 lb. per sq. inch, in the usual way and are then charged into storage vessels for sale under a pressure of about 10 lb. per sq. inch. The reduction in pressure is effected by passing the aerated water through a reducing valve arranged in a conduit between the high-pressure reservoir and the storage vessels. The gas accumulating in the reducing valve is returned to the aerating machinery by means of a pump, the charging of the storage vessels being suspended during the action of the pump.—W. P. S.

Curing process [for meat, etc.]. A. J. Boulton, London. From The Electric Meat Curing Co., Cleveland, Ohio. Eng. Pat. 23,183, Oct. 30, 1908.

The meat is placed in a tank containing strong brine and a current of electricity is passed through the brine, the electrodes being placed in porous cups situated at each end of the tank. The brine is cooled by circulating it through the tank and an outside tank, the latter containing a coil through which a cooling liquid is passed. The production of chlorine and sodium hydroxide about the electrodes is prevented by the use of a switch by means of which the direction of the current may be altered from time to time, or by the employment of an alternating current.—W. P. S.

Milk; Processes of treating — to produce a solid therefrom. G. V. Frye, Lexington, Ohio, U.S.A. Eng. Pat. 5133, March 6, 1908.

(B.)—SANITATION; WATER PURIFICATION.

PATENT.

Refuse and sewage; Conversion of — into manure. Soc. Générale des Engrais Organiques, Paris. Eng. Pat. 25,958, Dec. 1, 1908. Under Int. Conv., Dec. 4, 1907.

The process relates to the manufacture of a manure in the form of a fine powder. The refuse or sewage is delivered into a pit from which it is carried by means of a conveyor to a second pit. From this pit a bucket elevator raises the refuse and discharges it on to a third conveyor which delivers it to the grinding mills. Workmen draw the refuse from the conveyor to the hoppers of the mills, or automatic devices may be employed for this purpose. Any excess of refuse over the capacity of the mills is conducted back again to the first pit. The ground

material from the mills is conducted to a mechanical screening device which delivers the ground and sifted manure into transport trucks.—W. P. S.

XIX.—PAPER, PASTEBOARD, &c.

Bamboo and rice straw; Cellulose pulps from —. T. Knösel. *Wochenbl. Papierfabr.*, 1909, 40, 1603—1604.

PAPER pulp of high quality is now being manufactured in Brazil from bamboo, and the author has procured some of the raw material in use there, for treatment by his own process. The stems, having walls 15 mm. thick, were split and broken up prior to digestion, the oldest and hardest of the knots having been previously cut out. The material soon became softened under the chemical treatment and it was then readily reduced to a clean pulp by means of a wooden stirrer. The unbleached pulp had a brownish-yellow colour, with long, fine and strong fibres suitable for strong wrapping papers. It was easily bleached and then possessed a pure white colour and a silky lustre. On drying, it turned yellow when exposed to the light, presumably because suitable arrangements for thorough washing were not available. The yield amounted to 62 per cent. of air-dry, bleached cellulose. The author has also treated rice straw in a similar manner. This yields to the digestion process far more readily than bamboo and gives an extremely long fibre. The pulp could not be bleached quite white, owing to the presence of a fine brown dust in the material; the yield was 50 per cent. The author considers that both these materials would be capable of affording a cheap and important supply of high-grade pulp.—J. F. B.

PATENTS.

Size composition and method of making the same. C. K. Mills, London. From A. W. Harrington Co., New York, U.S.A. Eng. Pat. 9652, May 4, 1908.

A SIZING material suitable for use by paper-makers is made according to the following process. Rosin and soda ash are boiled in water and allowed to cool, when glue and starchy material which has been boiled in water, are added whilst hot. When cold, glycerin, formaldehyde, and Russian petroleum are added. Cassava can be used instead of the starchy material, and other natural oils in place of the Russian oil.—F. SHDN.

Cellulose acetate; Manufacture of objects from —. A. Schloss, Assignor to Fürst Guido Donnersmarck'sche Kunstseiden und Acetatwerke, Sydowsane, Germany. U.S. Pat. 922,340, May 18, 1909.

THE cellulose acetate is dissolved in formic acid and the solution is then introduced into an aqueous precipitating bath.—W. P. S.

Non-inflammable plastic substances [celluloid substitutes]; Process for the manufacture of transparent or opaque—, and apparatus therefor. S. Assadas, Lyons, France. Eng. Pat. 9982, May 7, 1908. Under Int. Conv., May 8, 1907.

SEE Fr. Pat. 387,537 of 1907; this J., 1907, 873.—T. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, & EXTRACTS.

Medicinal bark from the Ivory Coast; New —, and its alkaloid. E. Perrot. *Compt. rend.*, 1909, 148, 1465—1467.

IN 1897, A. Chevalier discovered a tree growing on the Ivory Coast, the bark of which was recommended by the natives as a febrifuge. The tree belongs to the family of the *Rubiaceæ*, but its exact botanical characters have not yet been determined, so the author calls it provisionally *Pseudo-cinchona africana*, A. Chev. The bark appears to contain a considerable quantity of an alkaloid. This has been isolated in the form of long needles, soluble in

alcohol, but insoluble in ethyl acetate and ether. A study of the physical and chemical characters of the alkaloid is in progress. Preliminary physiological experiments indicate that it possesses therapeutic value.—A. S.

Pirus toringo, Sieb.; Constituents of the bark of —. Y. Hirose. *Ber. der Pharm. Ges. von Japan*, Yaku-gazanehi, 1909, 1.

IN Japan the bark of *Pirus toringo*, N.O. *Rosaceæ*, is used for the preparation of a yellow lacquer, obtained by boiling this bark with potassium carbonate solution and precipitating the extract with alum solution. The lacquer is termed "Dzumi." The powdered bark is also used for adulterating powdered liquorice, gentian, etc. From the alcoholic extract of the bark, a glucoside, in white, glistening, acicular crystals, has been isolated, which, when recrystallised from methyl alcohol and acetone, has the composition $C_{21}H_{26}O_6 + 2H_2O$. The melting-point of the hydrated product is 135° — 137° , that of the anhydrous, about 240° . On hydrolysis, the glucoside, which has been called *toringin*, is split up as follows:— $C_{21}H_{26}O_6 + H_2O = C_{13}H_{16}O_4 + C_6H_{12}O_6$. The product, $C_{13}H_{16}O_4$, is identical with chrysin; the osazone of the separated sugar has the melting-point, 204° . From the mother-liquor of *toringin*, quercetin (*pirusquercitrin*) is obtained in yellow needles of melting-point 174° — 176° . It yields on hydrolysis quercetin and rhamnose.

Cubebin. E. Mameli. *Gaz. chim. ital.*, 1907, 37, II., 483—506; 1909, 39, I., 477—493, 494—508.

PURE cubebin prepared from specimens of different ages and origins has the composition, $C_{20}H_{26}O_6$. It melts at 132° C., and has the rotatory power, $[\alpha]_D = -45.45$ in chloroform. It contains two hydroxyl groups and its other reactions indicate that it has the constitution represented by the formula, $CH_2O_2C_6H_5[C_6H_3(OH)_2]C_6H_3O_2CH_2$. By the action of dehydrating agents on cubebin, *cubebinic ether*, $C_{20}H_{18}O_5$, is formed. An almost quantitative yield is obtained by the action of hydriodic acid on a cold solution of cubebin in excess of glacial acetic acid. The reaction product is poured into water, and the precipitate is purified by crystallisation from alcohol. *Cubebinic ether*, $CH_2O_2C_6H_5[C_6H_3(OH)_2]C_6H_3O_2CH_2$, m. pt. 78° C., $[\alpha]_D = +23.04^{\circ}$ in chloroform, forms fine white silky needles soluble in alcohol, benzene, acetic acid, and chloroform. It contains no hydroxyl or carbonyl groups, does not decolorize bromine water or potassium permanganate solution, and is not affected by hydrogen peroxide. When reduced with alcohol and sodium, it yields a monohydric, primary alcohol, *cubebinol*, $CH_2O_2C_6H_5[C_6H_3(OH)]C_6H_3O_2CH_2$. *Cubebinol* crystallises in white silky needles, m. pt. 92° C., $[\alpha]_D = +34.81^{\circ}$ in chloroform, soluble in chloroform, benzene, ether, pyridine, acetic acid, alcohol, toluene, and petroleum spirit. It yields an acetyl derivative, m. pt. 71° C., $[\alpha]_D = +23.12^{\circ}$ in chloroform, and a benzoyl derivative, m. pt. 154° — 155° C., $[\alpha]_D = -21.68^{\circ}$ in chloroform.—A. S.

Adrenaline reaction; A new characteristic —. S. Fraenkel and R. Allers. *Biochem. Zeits.*, 1909, 18, 40—43.

ADRENALINE solution when warmed with iodine acid or with potassium di-iodate and dilute phosphoric acid, gives a fine rose-red coloration, or an eosin-red colour in the case of very dilute solutions. 1 part of adrenaline in 300,000 of solution can be detected by this reaction. In carrying out the test, the adrenaline solution is mixed with an equal volume of N/1000 potassium di-iodate solution and a few drops of dilute phosphoric acid, and heated to incipient boiling. The red colour changes to brown on addition of ammonia. The red colour reaction depends upon the addition of iodine to the adrenaline molecule, and the authors hope to base a quantitative method upon it. The reaction is characteristic of adrenaline. (See also this J., 1908, 1082.)—A. S.

Camphor; Points of difference between natural, artificial and synthetic —. W. Lohmann. *Ber. deutsch. Pharm. Ges.*, 1909, 19, 222—230.

THE melting point is of no practical value in distinguishing natural from synthetic camphor, especially if monoxidised

camphene, borneol, or isoborneol be present in the synthetic product. The optical rotation of alcoholic solutions forms the best test, synthetic camphor being optically inactive, whereas natural camphor is markedly dextro-rotatory, so that in a mixture of the two, the amount of natural camphor present might be determined polarimetrically. The statement in text-books that artificial camphor does not give a syrupy liquid when titrated with an equal quantity of chloral hydrate, such as natural camphor affords, is erroneous. Pure synthetic camphor behaves exactly like natural camphor towards chloral hydrate. Probably the error has arisen from the presence of pinene hydrochloride in the synthetic camphor employed. Since borneol melts at 208°C ., camphene at 50°C ., and pure synthetic camphor at 175°C ., it would be possible to have a mixture of the three with the correct m. pt. Consequently small fractional sublimations should be made, and the melting points of the products determined: also the amount of unsublimable matter should be weighed. The presence of pinene hydrochloride as an adulterant of either natural or synthetic camphor is readily shown by heating with twice its weight of calcium hydroxide, free from chlorine, until all the camphor has volatilised. The residue is then treated with hot water filtered, and tested with silver nitrate reagent after acidifying with nitric acid. No opalescence should be evident. In the discussion, Stephan stated that for the celluloid industry (the largest consumer of camphor), it is absolutely necessary that the synthetic product should be free from chlorine. This is readily proved by a modification of Beilstein's test with a copper oxide bead. When the camphor is burned on copper wire and the wire is introduced into a Bunsen flame, the colour should be pure blue with no trace of green. Borneol and isoborneol are readily determined in synthetic camphor by the acetylation method, but if considerable quantities of these impurities are present, the sample should be diluted with xylol or with rectified turpentine oil, the acetyl value of which has been previously determined. The determination of the borneols is then easy. When camphor has been purified by recrystallisation from alcohol, the presence of a mere trace of the solvent will materially lower the melting point. Apart from this, the determination of the melting point affords a good indication of the purity or otherwise of artificial camphor. For celluloid manufacture, it is also important that the camphor should be free from all traces of acid, and its content of ash should in no case exceed 0.02 per cent.—J. O. B.

Pinene; *New method of hydration of* ——. P. Barbier and V. Grignard. Bull. Soc. Chim., 1909, 5, 512—526.

THE method described previously (this J., 1908, 90) is modified by the addition of 100 c.c. of acetic anhydride to the hydrating mixture, this addition being made in order to diminish the concentration of the water in the mixture. The experiments carried out with the modified process show that α -pinene is transformed into terpineol, small quantities of other substances being formed when the temperature of the reaction is raised. β -Pinene is hydrated almost completely in one operation, the disappearance of the pinene being correlative with the formation of fenchyl alcohol. As the pinene is hydrated, the residue left consists of a purer pinene than the original, a number of other hydrocarbons being the first to be acted upon. Hydrocarbons, which are hydrated less rapidly than α - and β -pinene, can be isolated by repeating the hydrating operation, and in this way the authors have separated from French pinene the following substances:—An impure hydrocarbon boiling at 150° – 152° C.; a camphene melting at 42° C.; and a saturated liquid hydrocarbon boiling at 157° – 160° C. W. P. S.

Perfumes of the violet; Synthesis of —, G. Merling and R. Welde. *Annalen*, 1909, **366**, 119—216.

The authors have succeeded in synthesising ironone (the odoriferous principle of the violet) which they term β -ironone (the perfume of which is even purer than that of the natural product) and also a new isomeride, termed

α -irone which has a perfume closely resembling that of β -irone or the natural product.

These compounds differ from α - and β -ionone only in the position of the cyclic double linking. The long side-chain is introduced by condensing acetone with the appropriate cyclic aldehyde (a cyclogeraniol) and the remarkable fact has been discovered that only those aldehydes of this class furnish compounds having the odour of violets in which the aldehyde group is adjacent to the methyl or the *gem*-dimethyl group; further the intensity of the perfume increases with the number of methyl groups adjacent to the aldehyde group. The starting point for these syntheses is isopropylidenacetoneacetic ester which when condensed with sodium acetoacetic ester yields ethyl isophoronecarboxylate (or ethyl δ -ketocyclogeraniolcarboxylate):—

When this is reduced with sodium and alcohol, three pairs of *cis-trans*-isomeric hydroxy-acids are produced, of which two pairs belong to the class of δ -hydroxydicyclogeranic acids or, as the authors call them, δ -hydroxy-cyclogeraniolcarboxylic acids. These four stereoisomeric acids can be converted one into the other at will. By elimination of water the acids furnish Δ^3 -cyclogeranic acid.

which exists in two stereoisomeric modifications, and by reducing δ -chlorocyclogeranioladienecarboxylic acid (one of the products of the action of phosphorus pentachloride on ethyl isophoronecarboxylate), Δ^4 -cyclogeranic acid, also existing in two stereoisomeric forms, is produced.

In the same reaction are also obtained the Δ^3 - and Δ^2 -cyclogeranic acids, the aldehydes of which yield α - and β -ionone respectively when condensed with acetone. The Δ^3 - and Δ^4 -acids are converted into the corresponding aldehydes as previously described (Merling, this J., 1908, 767), and by condensation with acetone give α - and β -irone respectively. For the mass of experimental detail reference to the original paper must be made.—I. C. C.

Benzene sulphonic-chloride; Preparation of —. R
Pummerer. Ber., 1909, **42**, 1802—1804.

The author has found that under suitable conditions (low temperature and large excess of chlorosulphonic acid), a yield of over 60 per cent. of the theoretical quantity of benzene sulphonie-chloride can be obtained by the direct action of chlorosulphonic acid on benzene. 400 c.c. of chlorosulphonic acid are cooled to -15°C . in an enamelled vessel of $\frac{1}{2}$ -litre capacity provided with an agitator, and then 78 grms. of benzene are added gradually in the course of 3—4 hours, the mixture being kept cooled and well agitated. The reaction product is allowed to flow in a thin stream on to ice, the temperature not being permitted to rise above 20°C . The mixture of benzene

sulphonic-chloride and sulphobenzide which separate is extracted with ether, the ethereal solution dried with sodium sulphate, concentrated, and the sulphobenzide precipitated by addition of petroleum ether. From the solution, after evaporation of the solvent, the benzene sulphonic-chloride (b. pt., 144° – 145° at 17 mm.) is recovered by distillation *in vacuo*; yield, 70–80 grms. With 10 times the quantities mentioned, the crude oil obtained can be freed from sulphobenzide by direct distillation *in vacuo* and a much better yield of benzene sulphonic-chloride obtained, viz., 1100 grms. or 62 per cent. of the calculated quantity.—A. S.

Acetone; Reaction [for the detection] of —. B. Bardach. Chem.-Zeit., 1909, 33, 570.

For the detection of acetone, 1 c.c. of a 3 per cent. solution of peptone is added to about 5 c.c. of the clear and nearly neutral liquid, and then Lugol's solution (4 grms. of iodine, 6 grms. of potassium iodide, and 100 c.c. of water), until an intense red-brown colour is obtained. On now adding 3 c.c. of ammonia, a dark brown coloration is produced which lasts about ten minutes (unless too little iodine be present), and in about an hour a precipitate separates, from which most of the liquid is poured off, the remainder, containing the precipitate, being acidified with hydrochloric acid. The development of a crystalline precipitate indicates the presence of acetone; but if the liquid become quite clear and remain so for an hour and a half, acetone may be regarded as absent. 0.01 per cent. of acetone is readily detected, and even smaller quantities with the aid of a microscope. The reaction is common only to compounds containing the group, $\text{H}_3\text{C}\cdot\text{CO}\cdot\text{C}$, and may, therefore, be used for the detection of acetone in the presence of alcohol. The value of the test is not affected by the colour of the solution to be examined.—F. SODN.

Ketones and aldehydes; Compounds of — with acids. A. Shukow and F. Kassatkin. J. Russ. Phys.-Chem. Ges., 1909, 41, 157–166. Chem. Zentr., 1909, 1, 1760–1761.

On adding the calculated quantity of camphor to cooled anhydrous nitric acid, a colourless viscous liquid is obtained, from which on continued cooling, long needles of the compound, $\text{C}_{10}\text{H}_{16}\text{O}\cdot\text{HNO}_3$, separates. This melts at 24°C . is easily soluble in alcohol, ether, petroleum spirit, and acetone, and deliquesces when exposed to the air. Another compound, $(\text{C}_{10}\text{H}_{16}\text{O})_2\cdot\text{HNO}_3$, melting at 2°C ., can be obtained by mixing solutions of nitric acid and camphor in petroleum ether. The compound, $\text{C}_{10}\text{H}_{16}\text{O}\cdot\text{H}_2\text{P}_2\text{O}_7$, is obtained in large crystals melting at 3°C . by heating a mixture of molecular proportions of camphor and phosphoric acid. On leading hydriodic acid gas into a solution of camphor in petroleum ether, reddish-brown crystals of the compound, $\text{C}_{10}\text{H}_{16}\text{O}\cdot\text{HI}$, m. pt. 29° – 30°C ., separate. A colourless compound of hydrochloric acid and camphor, m. pt. $4\cdot2^{\circ}\text{C}$., which decomposes in the air, is produced by the action of hydrochloric acid gas on powdered camphor. A liquid compound, which does not solidify at -35°C ., is also produced by the action of nitrogen trioxide on camphor. Compounds of nitric acid with benzophenone, benzaldehyde, naphthol, and methylonylketone were also prepared. (See also Ger. Pat. 206,695; this J., 1909, 383.)—A. S.

hydrocyanic acid; Formation of — by the action of nitric acid on phenols and quinones. A. Seyewetz and L. Poizat. Bull. Soc. Chim., 1909, 5, 489–492.

HYDROCYANIC acid is produced by the action of boiling nitric acid on a considerable number of phenols and quinones, or on compounds containing a phenol or quinone group in their molecule. The quantity of hydrocyanic acid produced by the reaction varies with the phenol or quinone employed; it is large in the case of simple monod poly-phenols and diminishes as the molecule becomes more acid. Resorcinol yields about 5.8 per cent. of hydrocyanic acid. The formation of this acid is always accompanied by the production of nitrous acid and the authors find that if substances be added which prevent the production of nitrous acid, such as urea, aniline,

etc., hydrocyanic acid is not formed. Further, considerable quantities of hydrocyanic acid are yielded by heating certain phenols with nitrous acid. (See also this J., 1909, 219.)—W. P. S.

Oilate and stearate of mercury. D. B. Dott. Chem. and Druggist, 1909, 74, 785.

MERCURIC oleate prepared by the B.P. method was found to contain 23.13 per cent. of mercury, when analysed by the method in which the mercury is reduced with hypophosphorous acid, washed, dried, and weighed. By treating the same preparation with hot nitric acid, adding hydrochloric acid to the solution, evaporating the liquid nearly to dryness, taking up the residue with water, and determining the mercury in the form of sulphide, the amount of that metal found was 22.27 per cent. The lowness of the result was attributed to the difficulty of complete extraction of the mercury. On the other hand, the reduction method with hypophosphorous acid tends to give results somewhat too high, and it is therefore advisable to heat the product of the reduction in order to volatilise the mercury, and then weigh any non-volatile residue. Mercuric stearate is more stable and generally more satisfactory in its properties than the oleate. A suitable method of preparing it is to dissolve 20 parts of commercial stearic acid in a boiling solution of $3\frac{1}{2}$ parts of sodium hydroxide in 140 c.c. of water. To this solution is added hydrochloric acid until a slight permanent oily layer separates, and this layer is then dissolved by the addition of just sufficient sodium carbonate solution. The solution is now mixed with a hot solution of $18\frac{1}{2}$ parts of mercuric chloride in about 70 parts of hot water, and the precipitate washed till free from chloride, dried below 100°C ., and powdered. A sample thus prepared yielded, on reduction with hypophosphorous acid in the presence of alcohol, 24.28 per cent. of mercury.—C. A. M.

PATENTS.

Therapeutic compounds [mercury derivatives of phenylarsonic acids]; Manufacture of —. H. S. Wellcome, London, and M. Barrowcliff, Dartford. Eng. Pat. 12,472, June 10, 1908.

MERCURY derivatives of phenylarsonic acids are obtained by heating these acids or their substitution products or derivatives or their salts (e.g., aminoazo or azoxy compounds), with mercuric oxide, mercuric or mercurous acetate, or other mercury salts. The derivatives thus formed combine with acids and with bases to form salts. The following substances, together with their salts and acetyl derivatives, and the salts of the acetyl derivatives, are claimed:—3-oxymercury-4-aminophenylarsonic acid, $\text{NH}_2\cdot\text{C}_6\text{H}_3(\text{HgOH})\text{AsO}(\text{OH})_2$; 3,5-dioxymercury-4-oxyphenylarsonic acid, $\text{C}_6\text{H}_2\text{O}_6\text{AsHg}_2$; 3-methyl-4-amino-5-oxymercuryphenylarsonic acid, $\text{C}_7\text{H}_{10}\text{O}_4\text{NAsHg}_2$; 3-methyl-4-oxy-5-oxymercuryphenylarsonic acid; 3,5-dioxymercury-4-oxy-1'-methylazobenzene-4'-arsonic acid; 3,5-dioxymercury-4-aminophenylarsonic acid.—T. F. B.

Therapeutic compounds [Salts of dibromobenzenic acid]; Manufacture of new —. P. A. Newton, London. From Farbenfabrik, vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 17,132, Aug. 14, 1908.

CLAIM is made for the manufacture and medicinal use of the calcium, magnesium, and strontium salts of dibromobenzenic acid. All these salts are white powders almost insoluble in water and alcohol.—F. SHDN.

Salt; Preparation of alimentary, ferruginous —. C. Millet and L. Massi, Paris. Eng. Pat. 23,917, Nov. 7, 1908.

10 GRMS. of a 10 per cent. solution of pure hydrochloric acid are added to 1 kilo. of sea salt, and 1 gm. of ferric oxide or of a ferric salt is thoroughly incorporated and kneaded with the acidified mixture for about one hour. The excess of free acid is afterwards neutralised by adding 40 grms. of tricalcium phosphate to each kilo. of the ferruginous salt mixture.—O. R.

Phenolphthalein compounds. Knoll and Co., Ludwigshafen on Rhine, Germany. Eng. Pat. 27,095, Dec. 14, 1908. Under Int. Conv., Dec. 21, 1907.

THE esters of phenolphthalein with carbonic acid, the middle or higher fatty acids, or with substituted aromatic acids may be used as aperients in place of phenolphthalein or its diacetate, dibenzoate, or dibenzenesulphonate. They are prepared by the usual methods of treating phenolphthalein with the halogenides, anhydrides, or esters of the acids. The preparation of the following esters is described:—The di-isovalerate, dibutyrate, salicylate, and carbonate.—T. F. B.

Lactic acid; Process of manufacturing —. P. M. Justice, London. From C. H. Boehringer Sohn, Nieder-Ingelheim on Rhine, Germany. Eng. Pat. 7094, March 24, 1909.

IN decomposing concentrated solutions of calcium lactate with sulphuric acid, a stiff paste is produced, which is exceedingly difficult to work up. It is found that a more or less thin paste is formed if concentrated lactic acid be added to the acid used for decomposition, or the lactic acid solution may first be added to the calcium lactate solution. Or the calcium lactate solution may be evaporated to dryness, and then treated with lactic acid and sulphuric acid. For example, 300 litres of calcium lactate solution of 10° B., coming from the fermentation process, are evaporated to 50 litres; 50 kilos. of a 50 per cent. solution of lactic acid are added, and then decomposition is effected by means of sulphuric acid. The lactic acid solution thus obtained is of 50 per cent. strength. —T. F. B.

Vanilla beans; Process of extracting essences and tinctures from —. E. M. Howell, New York, U.S. Pat. 921,251, May 11, 1909.

RAW ground vanilla beans, contained in a suitable closed vessel (the length of which is about $3\frac{1}{2}$ times its diameter), are treated with dilute alcohol which, by means of a jacket surrounding the lower part of the vessel, is heated until the temperature of the top layer is about 100° F. The column of solvent and beans is then cooled to the ordinary temperature, the liquid portion percolated through the ground mass, and the percolate returned to the vessel to complete the extraction.—J. C. C.

Sulphuric acid esters of the terpene series; Process for preparing acid —. Chem. Fabr. von Heyden A.-G. Ger. Pat. 208,790, March 29, 1908.

ACID sulphuric esters of terpene alcohols are formed in good yield by treating the alcohols with methylene sulphate, thus,

Peru balsam and formaldehyde; Process for obtaining a preparation, soluble in water, from —. O. Boerner. Ger. Pat. 208,833, July 28, 1906.

GASEOUS formaldehyde is led into a solution of Peru balsam in alcoholic alkali, which is warmed during the treatment. The product is soluble in water and in ammonia solution.—A. S.

Aloin and ferric compounds; Process for the preparation of compounds, soluble in alkali, from —. A. Dieffenbach and R. Meyer. Ger. Pat. 208,961, May 6, 1908.

A SOLUTION of aloin in aqueous ammonia or potassium hydroxide solution is treated with a ferric salt, preferably a basic salt, and the dark brown solution is evaporated under diminished pressure.—A. S.

Aromatic hydroxyalcohols; Process for preparing tertiary —. P. Hoering and F. Baum. Ger. Pat. 208,962, July 22, 1908.

By treating aromatic hydroxycarboxylic esters or their alkali salts with excess (two or three molecular proportions) of alkylmagnesium halides in ethereal solution in the cold, tertiary hydroxyalcohols are obtained: they are

isolated by treating the reaction product with dilute acids, extracting the ethereal solution with alkali, and precipitating by means of carbon dioxide. The preparation of *o*-amylolphenol, $HO.C_6H_4.C(OH)(C_2H_5)_2$, isopropylol-*m*-cresol, and *m*-isoamylolcresol, are described.—T. F. B.

Oxalic acid; Process for the preparation of — Oxidation of carbohydrates with nitric acid. A. Naumann, L. Moeser, and E. Lindenbaum. Ger. Pat. 208,997, June 4, 1907. Addition to Ger. Pat. 183,022, Aug. 1, 1905.

ACCORDING to the main patent oxalic acid was produced by the oxidation of sugar with nitric acid in presence of vanadium compounds, the latter acting as oxygen-carrier (this J., 1908, 183). It is now found that other carbohydrates such as starch, dextrin, gums, or cellulose which has been treated with sulphuric acid, may be used in place of sugar.—A. S.

Formic acid from formates; Process for the preparation of —. D. Strauss. Ger. Pat. 209,418, June 2, 1907.

THE claim is for the decomposition of formates by hydrofluoric acid for the production of formic acid. In the case of sodium formate, sodium fluoride is obtained as a valuable by-product, which may be sold as such, or may be decomposed with quicklime, with production of caustic soda and calcium fluoride, the latter being then treated with sulphuric acid to regenerate the hydrofluoric acid.—A. S.

Guanidine; Process for preparing —. C. Ulpiani, Portici, Italy. Ger. Pat. 209,431, Oct. 16, 1907.

DICYANODIAMIDE is converted almost quantitatively in guanidine by means of *aqua regia*. 500 c.c. of hydrochloric acid (sp. gr. 1.16) and 200 c.c. of nitric acid (sp. gr. 1.384) are added to a solution of 100 grms. of dicyanodiamide in 500 c.c. of water, and the solution is evaporated to about one-fifth of its original volume at a temperature of 60–65° C.; on cooling, practically pure guanidine nitrate crystallises out, the yield being about 90 grms.—T. F. B.

Alkylene-iminosulphonic acid salts; Process for preparing —. Chem. Fabr. von Heyden A.-G. Ger. Pat. 209,502, Feb. 19, 1908.

THE salts of aminosulphonic acid readily condense with aldehydes to form the salts of alkylene-iminosulphonic acids, $R.CH:N.SO_3M$, where R represents hydrogen, a carbon-containing radical, and M a metal or other acid-forming radical. The preparation of the methylene-iminosulphonates of sodium and ammonium, and barium ethyldeneiminosulphonate, are described in detail.—T. F. B.

Alkylloxymethyl ethers of aromatic hydroxy-compounds; Process for the preparation of —. P. Hoering and F. Baum. Ger. Pat. 209,608, May 2, 1907.

ALKYLOXYMETHYL ethers are produced by the action of halogenomethylalkyl ethers of the general formula $X.CH_2.O.R$ (X=halogen, R=alkyl) on alkali salts of phenols or their substitution products, polyhydric phenols or their monoalkyl ethers, aromatic hydroxyaldehydes, or aromatic hydroxycarboxylic acids.—A. S.

Hydroxyaldehydes and hydroxycarboxylic acid esters of organomagnesium compounds; Process for producing reactions between —. P. Hoering and F. Baum. Ger. Pat. 208,886, June 9, 1907.

AROMATIC hydroxyaldehydes or hydroxycarboxylic acid esters which cannot be satisfactorily treated according to Grignard's reaction, are converted into the corresponding alkylalkoxyalkyl ethers by the action of chloroalkyl ethers on their alkali salts. The alkylalkoxyalkyl ethers are then treated in the usual manner with alkylmagnesium halides, and the products treated with hydrolysing agents in order to remove the alkylalkoxyalkyl group. (See preceding abstract.)—A. S.

Aromatic aldehydes containing at least one hydroxyl group adjacent to the aldehyde group; Process for preparing —. Kalle und Co. Ger. Pat. 209,910, Jan. 9, 1908.

By condensing α -isatin derivatives with aromatic compounds which contain the grouping, $-(CH_2.CO)-$ or $-CH_2.C.OH-$, dyestuffs are formed which give coloured addition products with alkali hydroxides; by further treatment with alkali, these are decomposed, anthranilic acid or a derivative being eliminated, and an o -hydroxy-aldehyde formed. Thus, 1-hydroxy-2-naphthaldehyde is obtained from β -naphthol, 2-hydroxy-1-naphthaldehyde from α -naphthol, 2,6-dihydroxybenzaldehyde from resorcinol, and 1-hydroxy-4-methoxybenzaldehyde from monomethylresorcinol ether.—T. F. B.

serum capable of neutralising the action of typhus aggrassinæ; Process for the preparation of a —. Chem. Fabr. auf Actien, vorm. E. Schering, Ger. Pat. 209,816, May 3, 1907.

TYPHUS cultures are cultivated on liquid nutrient media, and the filtered solution, which contains a considerable quantity of the so-called aggrassinæ, is used in the customary manner for the preparation of an anti-aggrassinæ serum.—A. S.

dine, resorcinol, and formaldehyde; Process for preparing a condensation product from —. N. Weiss and A. Horowitz, Ger. Pat. 209,911, Dec. 1, 1906.

RESORCINOL (50 grms.) is dissolved in water (150 grms.), and iodine (8 grms.) is slowly added to the solution warmed to 50°C .; the solution is kept at 50°C . until it becomes yellow, when it is heated at 70°C . for five minutes. A 40 per cent solution of formaldehyde (9 grms.) is now added in two portions, and the brick-red mass thus formed is maintained at a temperature of 60°C . for a further period. The product is an odourless crystalline mass containing no free iodine, and 3.87 per cent. combined. It is of value as a dry antiseptic.

—T. F. B.

glycerol esters; Process for preparing mixed —. V. Vender, Ger. Pat. 209,943, April 27, 1906.

GLYCEROL acid esters of glycerol or polyglycerol, which contain α -hydroxyl-groups (especially the acetic or formic esters) are nitrated by means of sulphuric-nitric acid mixtures containing more nitric acid than sulphuric acid. It is stated that pure nitroacetin is obtained in good yield by nitrating acetin by this process. Mixtures of nitroacetin and nitroglycerin are obtained also from mixtures of acetin and glycerol, if the ratio of nitric acid to sulphuric acid is increased in proportion to that of acetin to glycerol. Nitroformins can also be obtained by the above process from formins.—T. F. B.

phthaliminoacetyl catechol ethers; Process for preparing —. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 209,962, April 9, 1908.

PHALIMINOACETYLCATECHOL ethers are readily formed by the condensation of phthalimino-fatty acid chlorides with catechol ethers in presence of aluminium chloride. Phthaliminoacetoveratrol and α - and β -phthalimino-p-nitrophenylveratrols are described in the specification.

—T. F. B.

lecithin from the seeds of lupins and the like; Process for obtaining —. H. C. Buer, Ger. Pat. 210,013, March 21, 1908.

LEICITHIN and similar seeds are freed from the skin, dried, extracted with hot 96 per cent. alcohol. The extract is evaporated to about 30–50 per cent. of its original volume, or until its alcohol content is not more than four-fifths that of the dissolved matter; it is then treated with water until its alcoholic strength is 80 per cent., and allowed to stand for a long time. The tinous mass of lecithin which is precipitated, is separated from the alcoholic solution which contains the bitter principles, and freed from all traces of fatty substances by agitation with 96 per cent. alcohol.—T. F. B.

Lecithin, fatty oil, and cholesterol; Process for the production of —. C. A. Fischer, Berlin. Eng. Pat. 11,597, May 28, 1908. Under Int. Conv., May 28, 1907.

SEE Fr. Pat. 390,683 of 1908; this J., 1908, 1176.—T. F. B.

Methylsuccinic acid; Alkyl esters of —. R. Berendes, Assignor to Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pat. 921,944, May 18, 1909.

SEE Fr. Pat. 395,447 of 1908; this J., 1909, 490.—T. F. B.

Aryl-alkyl-para-aminophenol. P. Rehlander, Charlottenburg, Assignor to Chem. Fabr. auf Actien vorm. E. Schering, Berlin. U.S. Pat. 922,040, May 18, 1909.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Development with diaminophenol; Correction of errors of exposure in —. A. and L. Lumière and A. Seyewetz. Bull. Soc. Franç. Phot., 1909, 25, 180–184.

IN developing negatives by means of diaminophenol in presence of sodium sulphite, contrasts can be diminished, and consequently under-exposed plates improved, either by increasing the proportion of sulphite in the developer, or by diluting the normal developer with water or with a 5 per cent. solution of sodium sulphite, the last method producing the best results. In developing over-exposed plates, contrasts may be increased either by adding sodium bisulphite or, preferably, potassium bromide to the normal developer. It has not been found possible to devise a method of correcting development similar to that worked out for pyrogallol (see this J., 1909, 109 and 627.—T. F. B.

PATENTS.

Colour screens for photography; Method of manufacturing —. G. S. Whitfield, Watford, Eng. Pats. 9044, April 25, 1908, and 9693, May 4, 1908.

A FILM of collodion or other vehicle is mounted on a suitable support of glass, etc., and dyed with an aqueous or alcoholic solution of one of the required colours. A protective coating of indiarubber, gutta-percha, bitumen, or paraffin wax, is then applied to cover a portion of the coloured film in the form of small spots; this is preferably done by spraying a solution of the protective agent in naphtha, etc., on the film by means of an aerograph spray or similar device. The dyestuff is now removed from the uncovered portions of the film by dissolving or bleaching, and these are then dyed with a second colour, and a further series of spots of the protective agent applied to the film. This treatment is repeated with as many colours as required (usually three), and the protective coatings are finally removed, the result being a screen composed of a number of small adjacent areas coloured with the different colours used.—T. F. B.

Developing panchromatic sensitive surfaces in non-actinic light; Process for —. R. Krayn. Ger. Pat. 209,937, Oct. 4, 1907.

It is found that photographic emulsions which have been colour-sensitised by dyestuffs capable of being decolorised by acids (*e.g.*, pinachrome), entirely lose their sensitiveness towards non-actinic light after a brief treatment with dilute acids: when dried, or when treated with alkalis, their colour sensitiveness returns. It is proposed, therefore, to treat exposed colour-sensitive emulsions for 10–20 seconds, in the dark, with an acid solution, *e.g.*, a 0.5 per cent. solution of sulphuric acid and then to develop them in an acid developer (*e.g.*, ferrous oxalate) in ordinary red light, or to treat them with the acid developer in the dark before exposing them to red light.

—T. F. B.

Coloured images; Process for producing — by bleaching-out. H. Stobbe. Ger. Pat. 209,993, Sept. 20, 1907.

The dyestuffs of the group known as "Fulgides" (anhydrides of the fulgemic acids, obtained by condensing certain aldehydes and ketones with esters of itaconic and terecaonic acids) are decolorised by the action of light, especially in presence of ether, chloroform, gelatin, collodion, etc.; their sensitiveness is further increased by iodine, nitrobenzene, phenol ethers, and essential oils, decolorisation being complete in less than one minute in some cases. It is proposed to utilise these "fulgides" for the production of coloured prints; for example, a red and a yellow "fulgide" and a dicyanine or pinacyanol may be applied to paper, which is sensitised by phenetol and exposed under a suitable negative. After removing the sensitisers by benzene, the prints are stable in light for a short time by treating them with a gum or resin, which delays further bleaching of the dyestuff. —T. F. B.

XXII.—EXPLOSIVES, MATCHES, &c.

Nitrocelluloses and smokeless powders. Ignition points of —. G. Finzi. Gazz. chim. ital., 1909, 39, I., 549–553.

In the author's first experiments, a test-tube containing 0.1 gm. of the explosive, dried at 50° C., was immersed in a paraffin bath at 100° C., and the temperature of the bath raised at the rate of 5° per minute. Numerous experiments showed that the ignition point of stabilised nitrocellulose powder varies from 185° to 187° C., and is not influenced by the nitrogen-content (11.55 to 13.44 per cent.) or by the method of stabilising (with water or with sodium carbonate solution). The ignition-point is lowered by heating more slowly, by compressing the wet powder, or by gelatinising the product. If the gelatinisation be effected with an ester, *e.g.*, ethyl acetate or nitroglycerin, then the ignition point of the gelatinised explosive is lower, the higher the nitrogen content. Small quantities of acid cause a considerable depression of the ignition point. A sample of nitrocellulose taken after the first boiling and containing a quantity of acid equivalent to about 0.2 per cent. of sulphuric acid had an ignition point of 124–125° C., whilst another sample containing only the merest trace of acid ignited at 165°–175° C.; in these tests the temperature was raised 5° per minute.

In the case of samples containing acid, the ignition point is raised by heating more slowly; for instance with the samples mentioned the respective ignition points were 132°–138° and 175°–178° C. when the temperature was raised 2° per minute. Tests of nitrocelluloses which have not been stabilised or were of inferior stability did not yield concordant results. Some tests were also made with smokeless powders. The results are summarised in the following table:—

Explosive.	Nitrogen content, per cent.	Ignition point with rise of temperature of	
		5° per min.	2° per min.
		°C.	°C.

PATENT.

Gunpowder; Manufacture of —. G. Trench and Lynn-Smart. Eng. Pat. 8358, April 15, 1908.

An explosive mixture is obtained by combining with gunpowder (100 parts), potassium or ammonium perchlorate (5 to 20 parts). The incorporation is carried out under edge runners in the wet condition. By the addition of perchlorate, the strength and regularity of the explosive force are said to be increased. (Reference is directed to Eng. Pats. 1939 of 1865, 1375 of 18, 9190 and 25,838 of 1898, and 20,216 of 1903; this J., 1898, 872; 1900, 71; 1904, 836).—G. W. McD.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS.

Hempel gas-burette; Modification of the —. J. F. Spence. Ber., 1909, 42, 1786–1787.

The four-way cock shown in the figure is substituted for the ordinary stopcock of the burette. Its object is to expel completely the air in the connecting-tube between the burette and the pipette. Either of the tubes, *a* or *b*, can be connected with the burette, or with the side-tube, *d*, but *c* cannot be connected with the burette. Either of the tubes being connected with the pipette, the liquid is drawn over till it fills the tube, *d*, and the connection between pipette and burette is then made. The other tube in the cock can be similarly used in taking a sample of gas.—J. T. D.

PATENT.

Lubricating] *Oil-testing apparatus.* S. v. Kapff. Ger. Pat. 209,399, May 6, 1909.

In this apparatus the oil to be tested is placed in a chamber in which a vertical spindle is rotated, the lower end of the spindle bearing with a definite pressure on a corresponding friction-surface fixed on the bottom of the chamber. In order to exert pressure on the spindle, this is enlarged at the lower end, and on the enlargement rests a cylindrical piece surrounding the spindle, and provided at its upper end with two projections on which rests the arm of a lever which can be loaded as desired. The cylindrical piece does not rotate.—A. S.

INORGANIC—QUALITATIVE.

Thio-oxalates. Jones and Tasker. See VII.

INORGANIC—QUANTITATIVE.

Mercury cathode; Use of the — [in zinc electro-analysis]. W. Böttger. Ber., 1909, 42, 1824—1839.

EXPERIMENTS on the separation of zinc from solutions of zinc sulphate are described. Before cutting off the current the author adds sodium acetate to the liquid in suitable excess. The zinc amalgam is then washed, first repeatedly with water, then with alcohol and ether successively. The ether which remains after removing the bulk with a pipette is mopped up with filter paper and the amalgam then dried by passing over it a current of air for at least 10 minutes. Blank experiments show that no loss of mercury occurs in this process. From 5 to 0.001 grm. of zinc as sulphate was dissolved in 10 to 30 c.c. of water to which 4 drops of strong sulphuric acid were added; the liquid was then electrolysed in an apparatus like a small weighing bottle, with a platinum rod sealed through the bottom, a current of 0.5 to 1 ampères being used by preference. The operation takes from 30 to 45 minutes for the actual electrolysis; when this is finished, 10 c.c. of 2*N*-sodium acetate solution is added. From 50 to 62 grms. of mercury were used; the cathode, which had an exposed surface of 6.6 to 15 sq. cm. The screw-shaped anode was placed 2 cm. above the cathode and made 500—800 revolutions per minute. The alcohol and ether may be replaced by ethyl alcohol for washing the amalgam. The results are very accurate, the error never exceeding 0.7 mgrm. of zinc when proper precautions are taken. (Compare *J.*, 1909, 545, 546).—E. F.

Nitric acid; Determination of — gravimetrically, by Busch's method. P. Pooth. Z. anal. Chem., 1909, 48, 375—376.

It is recommended that the solution of "nitron," used for the determination of nitric acid by Busch's method (*J.*, 1905, 291, 638), should not be made up in unnecessary quantity and should be kept in stoppered bottles, protected from the light. Also, the sulphuric acid may be replaced by hydrochloric acid, the maximum proportion being 100 c.c. of *N*/1 acid for every 0.1 grm. of nitrate, and, in this way, accurate results may be obtained in the presence of alkaline-earth metals.—F. SODX.

Copper oxalate; Precipitation of — in analysis. F. A. Jooch and H. L. Ward. Amer. J. Sci., 1909, 27, 448—458.

In connection with the volumetric estimation of copper by the oxalate method, Peters has shown (this *J.*, 1901, 1) that from solutions of copper sulphate, the precipitation of the metal by oxalic acid is practically complete when the volume of liquid is not too great, and the amount of copper present exceeds a certain minimum, the latter varying with the concentration and the quantity of precipitant used. Not only is copper oxalate appreciably soluble in oxalic acid, but, if the amount of copper present is small, supersaturation of the liquid occurs,

no precipitate being formed until sufficient copper is added to make the total exceed the required minimum, when practically the whole is precipitated. It is thus evident that for the complete precipitation of small as well as large amounts of copper by this method, the supersaturation of the liquid must be prevented, and the normal solubility of copper oxalate reduced to a minimum. With this end in view, the authors have experimented with solutions of copper sulphate and nitrate, and studied the effect upon the precipitation, of variations in the temperature, time of standing, quantity of precipitant used, and degree of concentration of the liquid. Precipitations were also made in the presence of varying quantities of nitric acid, sulphuric acid, acetic acid, and alcohol; and it was found that the most satisfactory medium consisted of a 50 per cent. acetic acid solution of the copper salt containing 5 to 10 per cent. of nitric acid. The addition of 4 grms. of oxalic acid to 100 c.c. of this liquid precipitated the copper completely, the presence of the nitric acid rendering the filtration more effective without influencing the solubility of the precipitate.—W. E. F. P.

Chromium, iron, aluminium, and zinc; Separation of — from each other. E. Pozzi-Escot. Bull. Soc. Chim., 1909, 5, 558—559.

THE solution containing the four metals is heated to boiling and treated with a strongly alkaline solution of sodium hypobromite. The ferric hydroxide precipitated is collected on a filter, dissolved in hydrochloric acid and re-precipitated by means of sodium hypobromite. After washing, the ferric hydroxide is again dissolved in hydrochloric acid and precipitated with ammonia in the usual way. The united filtrates, containing the aluminium, chromium, and zinc, are acidified with hydrochloric acid, boiled to expel the bromine, and the aluminium is then precipitated by the addition of ammonia. The filtrate from the aluminium hydroxide is acidified, boiled after the addition of a little alcohol, and the chromium is precipitated with an excess of ammonia. The zinc is finally thrown down as zinc sulphide in the filtrate from the chromium hydroxide.—W. P. S.

PATENT.

Uric acid in urine; Estimation [determination] of —. R. Weiss, London. Eng. Pat. 9726, May 5, 1908.

URIC acid in urine can be estimated by a process of titration with a standard solution of iodine in potassium iodide and an indicator such as carbon bisulphide. The titration is carried out in a glass tube sealed at one end,

and fitted with a cork or stopper, and provided with marks. The tube is filled to these marks with the indicator and a standard solution of iodine. Urine is added, followed by shaking till the carbon bisulphide is completely decolorised. From the amount of urine added, the amount of uric acid present can be ascertained.

— F. SUDS.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Polyhydric alcohols: Oxidation of — by a peroxylase system. E. de Stoecklin and E. Vulquin. *Compt. rend.*, 1909, 148, 1404–1406.

Iron tannate and hydrogen peroxide (this J., 1909, 111, 327) do not oxidise polyhydric alcohols effectively; but a solution of quinhydrone, to which ferric sulphate or chloride has been added in such quantity that the solution contains 1 mgrm. of iron per c.c., is much more active in this direction. The author calls this solution iron quinhydrone; and small quantities of it convert relatively large amounts of polyhydric alcohols to reducing sugars, both aldoses and ketoses. Glycol thus yields glycollic aldehyde; glycerol gives glyceric aldehyde and dihydroxyacetone; mannitol yields mannose and a substance giving the reactions of a ketose; dulcitol gives a ketose, and in all probability an aldose also; and sorbitol yields sorbose, the amount of material not being enough to allow of search for an accompanying aldose.—J. T. D.

Acetylation: Acids as accelerators in —. A. E. Smith and K. J. P. Orton. *Chem. Soc. Proc.*, 1909, 25, 166.

The speed of acetylation of *s*-tribromophenol in the presence of sulphuric, perchloric, and orthophosphoric acids has been measured. Whereas in acetic acid and chloroform solution, acetic anhydride has no perceptible action on *s*-tribromophenol at the ordinary temperature, even after keeping for several weeks, in the presence of perchloric and sulphuric acids, acetylation takes place very rapidly. Orthophosphoric acid (or phosphoric oxide) comes far behind as an accelerator. When the quantity of acid is small, the rate of the reaction is approximately proportional to its concentration. Comparing gram-molecular proportions, perchloric acid is about 2.5 times as effective as sulphuric acid. Chloroform is the medium in which acetylation is the most rapid, but acetic acid is only slightly inferior. Benzene and acetone are unfavourable to acetylation. A comparison of pyridine, acids, and sodium acetate as accelerators of acetylation by acetic anhydride, shows that both the two former are far superior. Pyridine is approximately as effective as perchloric acid and therefore superior to sulphuric acid.

Trade Report.

German chemical industry in 1908. *Chem.-Zeit.*, 1909, 33, 542–543, 551, 559, 566.

THE German chemical industry in 1908 participated in the general depression and was also adversely affected by foreign legislation, specially by the new English Patent Law, with its provision for compulsory working of patents. This necessitated the erection, in many cases, of branch works in England. It is hoped that an agreement will be arrived at between Germany and the United States in order to obviate a similar effect following the proposed new American Patent Law. The demand of the large colour works for acids and other heavy chemicals was considerably less than usual, and the prices of acids were forced down to a level at which the cost of production was no longer covered. Even at the reduced prices the production of sulphuric and hydrochloric acids could not be disposed of. The prices of nitric acid and ammonium sulphate fell in accord with the lower price of sodium nitrate. The market for soda products, especially caustic soda, was also unsatisfactory, although the price was maintained at about the same level as at the end of 1907. The potash industry, which depends mainly upon the export trade, suffered owing to the crisis in the United States and also owing to difficulties

attending the entry of new works into the Syndicate and the renewal of the agreement which expires at the end of 1909. The sales of crude potassium salts have not kept pace with the increase of the number of works and the sales of concentrated potassium salts have retrogressed. With regard to the by-products, the price of bromine increased somewhat, in consequence of a provisional agreement with American producers, that a magnesium chloride increased by 10 per cent.; the prices of calcium chloride and Stassfurt Glauber salt were somewhat lower, and the price of "bitter salt" fell almost to the level of the cost of production. The price of bleaching powder also fell, and is not likely to rise again owing to the unsatisfactory condition of the paper and textile industries. Increased home and foreign competition caused a reduction of the prices of phosphates and superphosphates. The home demand for ammonium sulphate showed no appreciable increase, but the exports were larger. A decreased production of coke, and hence also of ammonium sulphate is anticipated in 1909. It is probable that the reduced prices of sodium nitrate and ammonium sulphate are due partly to the introduction of the new nitrogenous fertilisers prepared from atmospheric nitrogen. The German producers of "Stickstoffkalk" have combined to form a syndicate. The trade in pharmaceutical chemicals was not so good as in 1907. The dyestuffs industry experienced a bad year; for the first time the exports showed a decrease, this being almost entirely due to diminished imports from the United States, China, and Japan. The trade in mineral colours was exceptionally bad, the exports being considerably less than in 1907. The ceramic colour industry had to meet increasing English competition. The industry of varnishes and lac-colours was satisfactory in the first half of the year, but the sales diminished considerably during the latter half, owing in some measure to the depression in the building trade. The price of oil of turpentine and its substitutes, linseed oil, shell and rosin all fell considerably, but the high prices of copals were maintained. In consequence of new commercial treaties, German exports of varnishes, especially to Switzerland, suffered considerably, and new branch works have been erected or existing ones enlarged, in Switzerland and Austria. The figures relating to the petroleum industry were as follows:—crude petroleum imports, 35,252 metric tons (26,944 in 1907); refined petroleum or mineral illuminating oil, consumption, 1,015,469 (993,719); imports, 1,016,331 (995,214); petroleum lubricating oils, imports, 216,887 (226,609) metric tons. The preparation of lubricating oils in Germany from the crude petroleum from Hanover has made great progress, and the German product now competes with foreign oils. The reduction of the abnormally high price for fats which began at the end of 1907 went on up to the end of February, 1908, after which the prices remained firm. The soap industry suffered from the competition of cheap washing powders. The trade in scented toilet soaps, which already has to meet severe foreign competition, would be seriously prejudiced by the proposed Government spirit monopoly and the increased tax on spirit. In most cases it would not be possible to raise the price sufficiently to cover the increased tax. Not only would the domestic trade suffer, but the export trade would probably, to a large extent, be lost. The German glycerin industry made considerable progress in 1908, owing, on the one hand, to the convention established in the spring to regulate the sale of refined glycerol, and, on the other hand, to the introduction of fat-hydrolysing processes into many works. Whilst previously the German demand for crude glycerin was met almost exclusively by imports, much larger quantities are now produced in Germany. The exports of matches diminished steadily, whilst large quantities were imported, especially from Belgium, at extremely low prices. The paper industry had a very unsatisfactory year. In the porcelain industry those firms producing articles for export to the United States suffered most, although sales were also even in the home market. Exports of cement from Germany diminished by 25 per cent. in 1908. The figures (in metric tons) for the German iron and steel industry in 1907 (in brackets) and 1908, were as follows:—production

on of pig-iron, 11,813,511 (13,045,760); consumption, 205,745 (9,020,196); imports (in terms of pig-iron), 4,244 (1,066,789); exports (in terms of pig-iron), 352,010 (5,092,353). The production of zinc, which amounted to 205,000 tons in 1907, increased by about 900 tons, Germany thus taking first place among the zinc-producing countries. The consumption amounted to 185,000 tons, and both imports and exports increased. Attempts to form a syndicate of the German, Belgian, and English zinc producers, had not come to a satisfactory issue at the end of 1908. The production and exports of copper showed a slight decrease; the imports increased from 157,585 to 188,095 metric tons, and the consumption from 160,217 to 188,095 metric tons. In the case of tin, the imports increased and the exports decreased. The exports of lead rose from 74,973 to 77,218, and the exports from 27,708 to 29,988 metric tons. The price of aluminium is considerably owing to the largely increased production.

—A. S.

Japanese trade in 1908. E. O. James. Chem. and Drugg., June 12, 1909.

THE annual return of the foreign trade of Japan has just been published; imports and exports combined show a falling-off of 112,377,084 yen when compared with the figures of 1907. Imports were again in excess of exports, the difference during the year being 58,011,789 yen. The following are the principal chemical imports:—

In consequence of the general depression in trade the import of aniline colours shows a decrease in 1908 of 808,072 kin against that of 1907. The total imports were 4,615,771 kin, drawn from the following sources: Great Britain, 55,353 kin; France, 55,798 kin; Germany, 3,718,959 kin; Belgium, 14,524 kin; Switzerland, 701,363 kin; Holland, 68,566 kin; and other countries, 1,318 kin. The trade in colours and dyes being closely connected with the Japanese export trade, more particularly as regards the spinning and weaving industries, its rise and fall much depends upon the state of those industries. Alizarin colours showed a slight increase, the figures for 1908 and 1907 being respectively 124,950 kin and 121,451 kin.

The output of sulphate of ammonia is still limited, the monthly output of various companies being 20 tons from the Osaka Gasworks, 10 tons Nagoya Gasworks, 10 tons Tokyo Gasworks, 5 tons Osaka Seimei, and 180 tons from the Government Ironworks. The Japanese article is much inferior to the imported, as it contains too much sulphuric acid.

Among exports of chemicals and drugs from Japan for 1908 were the following: Sulphur, 50,885,719 (over 29,000,000 went to Australia); Camphor, 1,807,565 (America and Germany largest buyers); Camphor oil, 1,259,983 (America and Germany largest buyers); Menthol, 55,406 (Germany and Great Britain largest buyers); Peppermint oil, 103,906 (Hong Kong 59,098

Chlorine	757,977	Straits Settlements.
Sodium carbonate	8,000	Switzerland.
Mercury	51,597	Spain.
Acetic acid	23,266	Denmark.

(in *tr.*) and Great Britain 24,816 were the largest buyers); Sulphuric acid, 2,689,991 (China, Hong Kong, and Dutch India being largest buyers); Fish and whale oil, 38,480,222, almost the whole going to Germany and Great Britain; Colza oil, 11,913,954 (Great Britain purchased 9,413,454); Vegetable wax, 3,817,374 (Hong Kong in *tr.*); Iodine (crude), 16,133 (Great Britain, Germany, and U.S.A. largest buyers); Potassium iodide, 22,969 (Great Britain, Germany, and U.S.A. largest buyers).

New Books.

ANNUAL REPORT OF THE CHIEF INSPECTOR OF FACTORIES AND WORKSHOPS FOR THE YEAR 1908. Reports and Statistics. [Cd. 4661.] Wyman and Sons, Fetter Lane, E.C. Price 2s. 4d.

THIS publication contains the general report of the Chief Inspector upon the work of the Factory Department in 1908, as well as statistical tables. Reports are included by the Divisional Superintending Inspectors, the principal Lady Inspector, the Inspector of Textile Particulars, the Inspector for Dangerous Trades, and the Electrical and Medical Inspectors.

At the end of the year there were upon the registers 110,691 factories and 149,398 workshops, not including men's workshops, warehouses, docks, wharves, quays, "buildings," railway lines and sidings, and factories and workshops under the charge of H.M. Inspectors of Mines.

DIE DESTILLATION INDUSTRIELLER UND FORSTWIRTSCHAFTLICHER HOLZARBEIT. VON WALTER B. HARPER. Erweiterte deutsche Bearbeitung. VON INGENIEUR R. LINDE. Julius Springer's Verlag, Berlin. 1909. Price, M.10. Bound M.11.

Svo volume, containing 299 pages of subject matter with 128 illustrations, an appendix of 9 additional pages, forming a compendium of patents taken out on the subject of the work in the United States and Germany, and the alphabetical indexes of subjects and names of authors. The subject matter receives the following classification and arrangement:—I. Historical and general. II. Principles of distillation. III. Necessary apparatus and plant for dry distillation. IV. Purification of the crude products. V. Apparatus and general arrangements in modern distillation works. VI. The process of wood distillation. VII. Purification processes. VIII. General considerations as to the erection of distillation plants. IX. The composition of wood and of its distillation products. X. Yields, and the valuation of the products. XI. Chemical oversight and management of a wood distillery.

Patent List.

Where a complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of Application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

12,906. Lee. Furnaces. [U.S. Appl., June 27, 1908.]* June 1.

12,958. Seaver. Apparatus for separating finely-divided materials.* June 2.

13,034. Schmidt. Liquefying and separating mixtures of gases. [Ger. Appl., Dec. 12, 1908.]* June 3.

13,440. Pawle. Vacuum filters. June 8.

13,551, 13,551, 13,555, 13,556, and 13,558. Gayley. Drying air. June 9.

13,553 and 13,557. Gayley. Drying air particularly for metallurgical purposes. June 9.

13,559. Aktiebolaget Separator. Centrifugal separators. [Swed. Appl., June 25, 1908.]* June 12.

COMPLETE SPECIFICATIONS ACCEPTED.

5011 (1908). Hodgkinson. See under VII.

12,077 (1908). Tarver and Coulson and Co. Apparatus for washing, separating, or concentrating substances of different specific gravities. June 9.

12,565 (1908). Humphrey. Compressing air or gases. June 16.

25,881 (1908). Fothergill and Clark. Mechanical filter. June 9.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

12,827 to 12,830. Harrison. Manufacture of metal filaments of incandescent electric lamps. June 1.

12,915. Maul. Treatment of fuel. June 1.

13,026. Clinie. Gas producers. June 3.

13,097. Burnett. Apparatus for extracting liquid from washed coal, &c. [Addition to No. 10,062 of 1907. June 3.

13,516. Cotton. Burning fuel for heating furnaces, kilns, and ovens.* June 9.

13,604. Simmonds. Manufacture of gas. June 10.

13,796. Zindler. Manufacture of gas by dry distillation of fuel.* June 11.

COMPLETE SPECIFICATIONS ACCEPTED.

12,446 (1908). Jabs. Gas generators. June 16.

12,720 (1908). Soc. Franç. d'Incandescence par le Gaz. Manufacture of incandescence electric lamp filament. June 16.

982 (1909). Koppers. Gas and coke oven plant. June 9.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

COMPLETE SPECIFICATION ACCEPTED.

16,881 (1908). Testelin and Renard. Apparatus for making a spirit by treating petroleum. June 9.

IV.—COLOURING MATTERS AND DYESTUFFS.

APPLICATIONS.

13,323. Johnson (Badische Anilin und Soda Fabrik). Manufacture and employment of anthracene colouring matters. [Addition to No. 9888 of 1909.] June 7.

13,727. Newton (Bayer und Co.). Manufacture of dyestuffs. [Addition to No. 5383 of 1909.] June 11.

COMPLETE SPECIFICATIONS ACCEPTED.

13,789 (1908). Imray (Meister, Lucius, und Brünig). Manufacture of pentabromindigo. June 9.

15,355 (1908). Imray (Meister, Lucius, und Brünig). Manufacture of dyestuffs of the anthracene series. June 9.

18,023 (1908). Meister, Lucius, und Brünig. Manufacture of brominated derivatives from indigo white, its substitution products, and dyestuffs thereof. June 9.

6272 (1909). Chem. Fabr. vorm. Sandoz. Manufacture of dyestuffs of the gallocyanine series. June 9.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

APPLICATIONS.

13,227. Kleinewefers. Machine for mercerising cotton. June 5.

13,276. Naylor and Naylor. Dyeing machine. June 5.

13,483. Robertson. Calico-printing machines. June 5.

13,493. Dobson. See under XIX.

13,672. Adam (Erste Triester Reisschul-Fabr.). See under XIV.

13,772. Laverigne. Manufacture of waterproof fabrics. [Fr. Appl., June 12, 1908.]* June 11.

13,790. Keller. Treatment of alkaline fluids to render them fit for further use after boiling cotton and other goods therewith in connection with bleaching.* June 11.

COMPLETE SPECIFICATIONS ACCEPTED.

11,959 (1908). Dreaper. Manufacture of artificial materials. June 9.

12,455 (1908). Hübner. Production of designs or ornamental and colour effects on fabrics. June 16.
22,097 (1908). Ransford (Cassella und Co.). Dyeing with chrome colours. June 9.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

12,837. Jennison. Manufacture of bleaching liquid. June 1.
12,966. Marks (Willson). Production of calcium carbide.* June 2.
13,697. Greenwood. Manufacture of tubes, crucibles, and other articles of magnesia. June 11.
13,718. Scales and Manbré. Manufacture of zinc chloride. June 11.
13,848. Carriek and Pattison. *See under XIII.A.*

COMPLETE SPECIFICATIONS ACCEPTED.

5011 (1908). Hodgkinson. Apparatus for evaporating liquid from brine for producing salt, or for evaporating other solutions. June 16.
11,864 (1908). Newton (Bayer und Co.). Manufacture of alkali hydrosulphites. June 9.
16,690 (1908). Craig. *See under X.*
27,878 (1908). Erlenbach. Manufacture of ammonium sulphate. June 16.

VIII.—GLASS, POTTERY, AND ENAMELS.

APPLICATION.

13,515. Cotton. *See under IX.*

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

13,068. Perpignani and Candlot. Lime and cement kilns.* June 3.
13,183. Lodge. Manufacture of cement for building purposes. June 5.
13,515. Cotton. Producing heat in furnaces for firing brick and pottery kilns. [Australian Appl., June 9, 1908.]* June 9.

COMPLETE SPECIFICATION ACCEPTED.

11,522 (1908). Timofeff. Manufacture of cement for building, &c. June 9.

X.—METALS AND METALLURGY.

APPLICATIONS.

12,894. Gibb. Treatment of oxidised ores or products of copper mixed with gangue. June 1.
12,927. Harries. Calcining and smelting furnace for ores. June 2.
13,073. Dellwik. Agglomerating fine ores, metalliferous residues, &c. June 3.
13,081. Halvorsen and Johansen. Treatment of iron ores. June 3.
13,218. Richardson. Manufacture and treatment of steel. June 5.
13,240. Auchinaebie. Treating ores of vanadium, uranium, chromium, &c., and manufacture of vanadium and other iron or steel therefrom. June 5.
13,291. Ruthenburg. Smelting sulphide ores, &c. June 7.
13,330. Ackermann. Manufacture of fluxes for use in soldering.* June 7.
13,427. Reynolds. Manufacture of steel. June 8.
13,445. Clark. Method of copperising iron.* June 8.
13,512. Cowper-Coles. Production of aluminium. June 9.
13,513. Cowper-Coles. Annealing iron and steel. June 9.

13,552. Gayley. Operating blast furnaces and converters.* June 9.
13,553 and 13,557. Gayley. *See under 1.*
13,625. Merton. Ore roasting furnaces. June 10.
13,839. Wheatley. Red-coloured alloy. June 12.
13,849. Carriek and Pattison. Treatment of pyritic copper and copper-nickel ores.* June 12.

COMPLETE SPECIFICATIONS ACCEPTED.

11,996 (1908). Hess. Extracting copper from its ores, mattes, &c. June 9.
12,324 (1908). Boulé (Jones). Manufacture of iron and steel. June 16.
12,494 (1908). Finfroek. Aluminium solder. June 16.
13,120 (1908). Pearlite Steel Co., and Charlier. Treatment of low-grade steels. June 16.
16,056 (1908). New Delaville Spelter Co., and Shortman. Refining zinc during extraction by distillation. June 9.
16,690 (1908). Craig. Extraction of alkaline salts from blast-furnace tar. June 9.
18,653 (1908). Côte and Pierron. *See under XI.*
19,380 (1908). Howard and Hadley. Treatment of fumes of spelter furnaces. June 9.
19,882 (1908). Angél. Reduction of complex sulphide and other ores. June 16.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

13,036. Cowper-Coles. Electrodeposition of metals. June 3.
13,037. Cowper-Coles. Electrodeposition of iron. June 3.
13,295. Nathusius, and Westdeutsche Thomasphosphat Ges. Electric furnaces. [Addition to No. 7188 of 1908.]* June 7.

COMPLETE SPECIFICATION ACCEPTED.

18,653 (1908). Côte and Pierron. Electric furnace for the continuous extraction of zinc from ore. June 16.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

[COMPLETE SPECIFICATION ACCEPTED.

21,822 (1908). Bloxam (Jacobi). Soap frames. June 9.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, &c.

(A.)—PIGMENTS, PAINTS.

APPLICATIONS.

12,862. Mayer. Gold, silver, bronze, and aluminium paints. June 1.
13,679. Hopkins and Barnett. Recovery of the ingredients of oily inks.* June 10.
13,848. Carriek and Pattison. Black magnetic iron oxide utilisable as a pigment. June 12.
13,865. Machtoff. Production of carbon black.* June 12.

(C.)—INDIA-RUBBER.

APPLICATIONS.

13,570. Kautschukges. Schön und Co. Production of caoutchouc. [Ger. Appl., April 29, 1909. Addition to No. 4692 of 1906.]* June 9.
13,715. Bradley, Thew, and Gilbey. Manufacture of artificial or synthetic rubber. June 11.

COMPLETE SPECIFICATIONS ACCEPTED.

4484 (1908). Gare. Manufacture of hard rubber or ebonite. June 9.
7302 (1909). Soc. Franç. de la Viscose. Manufacture of a product from caoutchouc and cellulose. June 16.

XIV.—TANNING, LEATHER, GLUE, SIZE, &c.

APPLICATIONS.

- 12,908. Svedberg. Production of colloidal sols or gels.* June 1.
 13,601. Schütze. Manufacture of a solid plastic material from curd or casein. [Ger. Appl., Sept. 23, 1908.]* June 10.
 13,672. Adam (Erste Triester Reisschal-Fabr.). Manufacture of sizing or finishing media. [Addition to No. 29,130 of 1904.] June 10.

XVII.—BREWING, WINES, SPIRITS, &c.

APPLICATIONS.

- 12,881. Boulton (Henius). Brewing apparatus.* June 1.
 13,415. Epstein. Treatment or utilisation of yeast. June 8.

COMPLETE SPECIFICATIONS ACCEPTED.

- 19,348 (1908). Carroll. Distilling spirits. June 16.
 6087 (1909). Valentin. Mashing malt for brewing. June 9.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; AND DISINFECTANTS.

(A).—FOODS.

APPLICATIONS.

- 13,767 to 13,769. Henri, Helbronner, and Von Recklinghausen. Sterilisation of liquids. June 11.

COMPLETE SPECIFICATION ACCEPTED.

- 12,672 (1908). Gabler-Saliter. Drying milk and the like. June 16.

(B).—SANITATION; WATER PURIFICATION.

APPLICATIONS.

- 13,488. Adams. Sewage purification apparatus. June 9.
 13,702. Coplans. Rapid preparation of potable water. June 11.

XIX.—PAPER, PASTEBOARD, &c.

APPLICATIONS.

- 12,976. Reeser. Manufacture of sheets or objects of acetylcellulose.* June 2.
 12,992. Vieweg. Manufacture of concentrated cupro-ammoniacal solution of cellulose. June 2.
 13,365. Preatoni. Production of transparent or translucent designs, &c., in paper. June 8.
 13,493. Dobson. Bleaching cellulose, wood pulp, and other fibrous materials. June 9.

COMPLETE SPECIFICATIONS ACCEPTED.

- 24,809 (1908). Brandenberger. Treatment and application of cellulosic films. June 16.
 7302 (1909). Soc. Franç. de la Viscose. *See under XIII C.*
 7430 (1909). Marino. Preparation of soluble cellulose. June 9.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

APPLICATIONS.

- 13,125. Wellecome and Thompson. Preparation of substances for therapeutic use. June 4.
 13,828. Wellecome and Pyman. Manufacture of therapeutic compounds. June 12.

COMPLETE SPECIFICATIONS ACCEPTED.

- 12,405 (1908). Buer. Obtaining lecithin free from bitter alkaloids from the seeds of lupinus and other podded plants. June 16.
 1532 (1909). Chem. Fabr. auf Actien, vorm. E. Schering. Manufacture of sticks, tablets, and filaments of camphor. June 9.
 4128 (1909). Imray (Meister, Lucius, and Brüning). Manufacture of 1-p-dialkylaminoaryl-2,4-dialkyl-3-oxymethyl-5-pyrazolones. June 16.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATIONS.

- 13,328. Brandenberger. Manufacture of photographic films.* June 7.
 13,331. Lesmüller. Flash-light powders.* June 7.

XXII.—EXPLOSIVES, MATCHES, &c.

APPLICATIONS.

- 12,988. Burgess. Compound for neutralising the noxious fumes produced by blasting. June 2.
 13,103. Carré. Manufacture of matches. June 3.
 13,376. Garroway. Manufacture and use of explosives and explosive shells, mines, &c. June 8.

COMPLETE SPECIFICATION ACCEPTED.

- 22,555 (1908). Lezinsky. Explosive compounds and their manufacture. June 16.

Official Notices.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY.

The KING, who was accompanied by the Queen, the Prince and Princess of Wales, and Princess Victoria, laid the first stone of the new buildings of the Imperial College of Science and Technology at South Kensington, on July 8th. The ceremony took place in a marquee erected on the site of the new buildings.

Lord CREWE delivered an address to the King on behalf of the governors, professors, students, and staff of the College, in the course of which he said:—

"The Imperial College, founded under a Royal Charter granted by your Majesty on the 8th of July, 1907, represents the latest and, as we trust, the most effective development of the great movement towards scientific and technical education which arose out of the Exhibition of 1851.

"Standing at South Kensington, in the midst of the imposing buildings which mark the progress of that education in its various branches, we cannot forget that it was to your Majesty's father, the illustrious Prince Consort, that the movement largely owed its original inspiration. At a time when small regard was generally paid to either scientific or artistic instruction, the wise foresight of his Royal Highness anticipated what is now universally recognised as one of the prime needs of our national life.

"Of the institutions now comprised in the Imperial College, the Royal School of Mines was not entirely transferred from its original home in Jermyn Street until the year 1890. The Royal College of Science did not receive its title until 1890, having gradually gathered under one roof the scientific departments, such as those of chemistry, physics, geology, and biology, which had grown up round the Royal School of Mines, with which it was then incorporated. In 1906 the new buildings in Imperial Institute Road provided accommodation of the most improved kind for the study of chemistry and physics. Meanwhile the Corporation and Livery Companies of the City of London had planned the Central Technical College, of which your Majesty laid the first stone in the year 1881, for the study of chemistry and, in particular, of engineering. As the result of the report of a Departmental Committee, instituted by the Board of Education in 1904, the three colleges were welded into the new Imperial College, with the declared object of giving the highest specialized instruction and of providing for the most advanced training and research in the various branches of science, especially in its application to industry.

"The further development which we trust will result in the rising of an important group of buildings in the neighbourhood of this stone has been rendered possible, in the first place, by the Royal Commissioners for the Exhibition of 1851, who have given the sites, by the liberal grants provided by the Government and the London County Council, and by the generosity of private donors, among whom the late Mr. Alfred Beit, other members of the firm of Wernher, Beit, and Co., the Goldsmiths' Company, and the Bessemer Memorial Committee have been conspicuous.

"It is the earnest, and we believe, well-grounded hope of the governors that this Imperial College, thus honoured to-day by your Majesty's countenance and approval, and by that of her Majesty the Queen, may in the coming years justify its title by providing a centre of the most advanced teaching and research in science on its practical side, not only for the United Kingdom, but for the whole of your Majesty's dominions, and that it may stand second in dignity and character to no other kindred institution in the world."

The King then read the following address, which his Majesty afterwards handed to the Chairman of the governing body:—

"I thank you most heartily on behalf of the Queen and myself for the address from the governors, professors, students, and staff of the Imperial College of Science and Technology. It is a great pleasure to me to lay the foundation-stone of your new buildings.

"The concentration of various associated colleges into one institution, which was effected by our Order in Council of July, 1907, has always seemed to me to be an admirable scheme for the furtherance of scientific instruction, which my dear father had so much at heart; and the names which appeared in the first list of the members of the governing body were sufficient in themselves to give the College a very high status in the educational world.

"The purposes of the College, as stated in the charter, are to give the highest specialized instruction and to provide the fullest equipment for advanced teaching and research in various branches of science, especially in its application to industry. In recent years the supreme importance of higher scientific education has, I am happy to say, been fully recognised in England; and as time goes on I feel more and more convinced that the prosperity, even the very safety and existence, of our country depend on the quality of the scientific and technical training of those who are to guide and control our industries. The rapid growth of knowledge makes it necessary for the teacher of any branch of applied science to be a specialist of a high order, and the most accomplished specialist cannot impart the full advantage of his knowledge without that complete provision of apparatus for research and instruction which this College will supply.

"The College has already given admirable results, and we may well look for a steady increase in the number of students and in the efficiency of the instruction provided.

"The thanks of the country are due to those public-spirited donors through whose generosity a large portion of the funds have been provided for this great work, and I join in your appreciation of their munificence. I think it is especially fitting that the great discoveries of the late Sir Henry Bessemer, to which the remarkable development of the engineering industries in the last half-century is largely due, should be commemorated by the equipment of the new laboratories of this institution.

"I pray that the blessing of God may attend the future of the College and the high destinies which I anticipate for its work."

The King then laid the foundation-stone, and the brief ceremony concluded.

The land on which the new buildings will be erected, consists of three plots in Prince Consort Road, one to the north and two to the south, containing a total area of about five acres, and having a combined frontage of about 1000 ft. towards the Prince Consort Road and a return frontage of about 190 ft. towards Exhibition Road.

The new buildings will accommodate the mining, metallurgical, geological, and engineering departments. The three former will occupy the west end of the building; engineering will occupy the east end and will adjoin the City of London and Guilds Institute, thus greatly increasing the facilities for the engineering work at present carried on in that building.

The mining department will include on the lower floor a large top-lighted court about 250 ft. long and 120 ft. wide, designed to accommodate mining plant illustrative of the machinery and methods of ore extraction. The equipment for this is being supplied by the Bessemer Memorial Committee.

Another court adjoining will contain the roasting and smelting furnaces, in connection with which are the laboratories for wet and dry assay, with balance-room, lecture room, laboratories for micrography, pyrometry, electric metallurgy, the advanced course of metallurgical operations, and the equable temperature room. In connection with the mining department are two large

lecture rooms, museum, and drawing office, machinery, assay, laboratory, and departmental library.

The geological department on the second floor contains laboratories for paleontology, petrology, mineralogy, economics, and rock cutting, a museum 86 ft. by 40 ft., elementary laboratories, large drawing office, and research room.

The engineering department will occupy the whole east block on all floors. On the lower floor is a hydraulic laboratory 180 ft. by 16 ft., the equipment for which is being provided by Mr. G. Hawksley. There will also be large top-lighted courts, 112 ft. by 102 ft. and 112 ft. by 42 ft., to accommodate extensions, testing, and other engineering plant.

The other floors will consist of lecture rooms, class rooms, professors' rooms, and drawing and examination rooms for the various departments as may be from time to time required—such as railway and traction engineering, naval architecture, and bridge construction.

It is hoped to provide a students' union on the plot which lies to the north of Prince Consort Road. This building will contain on the ground floor a lounge hall, large dining room, and kitchens, smoking room, ladies', guests', and committee rooms. On the upper floor will be provided a large concert and debating room, to be used also as gymnasium, library, and reading room, and rooms for staff with a separate entrance.

INTERNATIONAL EXHIBITION, BRUSSELS, 1910.

The British Section of the International Exhibition, to be held next year in Brussels, from May to October, is in charge of a new Department of the Board of Trade, which furnishes the following information:—The Royal Commission, of which the Prince of Wales is the President, has its offices in Queen Anne's Chambers, 30, Broadway, Westminster. The Chairman is the Earl of Lytton, and the Vice-Chairman Sir Swire Smith. Committees have been formed for the various staple industries and for groups of allied industries. Mr. V. F. Wintour, the British Commissioner General, is approaching all the staple trades of the country with a view to secure an exhibit showing the scope and real importance of British manufactures.

A prominent position in the Exhibition has been secured for the general section; visitors must pass through the British Galleries to reach those of Germany, the United States, France, Italy, and other nations. In the Machinery Hall a space of 263,410 square feet has been allotted to Great Britain in the centre.

Except in the case of machinery, the only charge made within the Exhibition itself is a low charge for space; and tenders will be obtained from Belgian contractors for the installation of machinery. This charge for space covers the provision of showcases, the cost of the general decorative scheme, the handling of exhibitors' goods, and the publication of a catalogue in French and English.

"Handling" means that officials of the Commission will take delivery of packages at the Exhibition entrance; unload and place them on the space allotted; take away, store, and return the packing cases; and re-load at the close of the Exhibition. Further, the Commissioners will provide, free of cost, as far as possible, an adequate supply of unskilled labour to assist exhibitors with the installation of their goods. Machinery will involve, of course, the additional cost of foundations and shafting; that of main-switches, safety fuses, and motors for electricity, stop-valves for steam, and valves and motors for water; and that of the power used for driving. Crane power is free of charge.

Showcases in a uniform style will be provided for exhibitors in the British Section. Exhibitors are not required to use these cases, or any cases. They may provide their own, so long as these are not destructive to the national scheme. But the provided cases may be had in all sizes and for all positions, and they are dust-proof and made of seasoned mahogany. Samples may be seen at the offices of the Royal Commission, 30, Broadway, Westminster.

The tariff of charges for space is as follows:—

	Per sq. ft.	s.	d.
Including the use of an isolated showcase, or part of a case having more than one frontage	6	0	
Including the use of a wall case	4	0	
Including the use of a platform and ornamental facade without glass	4	0	
Including the use of a platform only	2	6	
On wall or screen	2	6	
In the Machinery Hall, including the use of platform and hand railing where required	2	6	

Motive power.—The Royal Commission will defray half the charges made for motive power by the Belgian Administration, on all machinery driven to illustrate processes of manufacture. Thus exhibitors will pay:—

For steam (133 lb. pressure), $\frac{1}{2}$ centime per kilogramme	
For gas	1s. 3d. per 1000 feet
Electricity (2 by 220 volts continuous), $\frac{1}{4}$ d. per kilowatt hour.	

Water will be supplied free for pumps or condensers. The charge for pure water in the Machinery Hall will be 1s. 10d. per 1000 gallons (50 lb. pressure), and in the Industrial Hall 1s. 8d. per 1000 gallons for domestic and 10d. for industrial purposes.

Not only will there be crane power, but the laying of foundations by Belgian contractors will be superintended by a competent engineer employed by the Royal Commission. With the above particulars, the railway and shipping freights, and the contractors' tender, an exhibitor of machinery can make his calculations with a degree of confidence not hitherto possible.

Other facilities.—The special catalogue for the British Section, published in English and French, will give a free insertion of twelve lines; the general catalogue a free insertion of four shorter lines.

All necessary steps will be taken by the Belgian Government for the protection in Belgium of inventions, industrial designs, and trade marks.

A suite of rooms will be provided for exhibitors' agents. There will be a reference library and a staff of high-class interpreters attached to the establishment, and it will be furnished with all the necessary equipment for transaction of business, correspondence, and so forth.

Reduced transport.—The Belgian State Railways, charging full rates on the outward journey, will return exhibit to their termini free of charge. The British railway companies will make a reduction of 50 per cent. on returned exhibits not sold, and travelling by the same route to the station from which they were sent out. Twelve shipping companies have also agreed to this 50 per cent. reduction.

London Section.

Meeting held at Burlington House on Monday, June 7th 1909.

DR. J. LEWKOWITSCH IN THE CHAIR.

DISCUSSION ON INDUSTRIAL FELLOWSHIPS

Prof. ROBERT K. DUNCAN (University of Kansas) in opening the discussion, said that, in an article in the "North American Review" for May, 1907, and later in a work ("The Chemistry of Commerce," Harpers) intended to draw the attention of American manufacturers to the applicability of modern science to industrial operations he had advocated the establishment of Industrial Fellowships.

It was not the function of a professor of industrial chemistry in a University to establish courses and laboratories for undergraduates who proposed to become chemists. Current industrial practice was always ahead of the text book, and laboratories of industrial chemistry notwithstanding all their apparatus and small scale

processes, failed to teach adequately, and gave the student an exaggerated idea of his utility in factory life. Moreover, this teaching was obtained at the expense of pure chemistry and culture, for by taking industrial chemistry, the student must sacrifice some physical chemistry, organic chemistry, and analysis, to say nothing of cultural studies.

The condition of American manufacture in respect of chemical progress and efficiency had been bad. A wealth of raw material ready to hand, an excessive tariff, a facility for business intrigue which compensated for waste in the factory by combinations to eliminate competition, and the needs of an expanding and not too particular population, all these had combined until a few years ago to cause waste in manufacture. Then came over-production, in business intrigue there was no more to learn, raw material had accumulated in the hands of a few, and the tariff, high as it was, could no longer exclude many goods made under scientific supervision, and was moreover itself in unstable equilibrium. American manufacture was approaching a crisis, and began to realise that safety lay only in efficiency. To-day, few men had any idea of the ever-increasing anxiety of the American manufacturer to secure factory efficiency. Already the supply of research chemists was inadequate, and during the next five years the need must increase.

At the present moment, the American manufacturer—with certain notable exceptions—had neither the knowledge nor the experience requisite to establish successful scientific research. He did not know what his problems were nor their relative importance, what kind of knowledge or what men were required to solve these problems; nor how to judge the qualifications of the men available for his purpose. He could not estimate a proper expenditure for laboratory space and supplies or for the libraries which such men would require, nor could he co-ordinate their work with the factory operations, or the work of one with another, so that they might be mutually helpful. Finally, he did not know how to systematise the work of his scientific staff, how to estimate their progress as an indicator of real efficiency, nor how to treat a man of science in giving him either power or trust. This last was responsible for the failure of much American factory research, the condition of the research chemist in an American factory being often actually pitiable.

The above considerations were, taken together, responsible for a scheme by which, in a spirit of sympathetic co-operation, the University and the manufacturer might both profit, and the public through both. This scheme of Industrial Fellowships had, during the last two years, undergone a somewhat notable development, not only in the number and value of the Fellowships established, but also in the increased advantages for the University which had been obtained from the donors. It made no pretension of having reached its ultimate development; all that could be said was that it had shown more strength than weakness in every one of its constituent factors.

Most of the Fellowships so far established had arisen through letters of inquiry from without. Owing to the fact that they had no relation to ordinary Fellowships, and that the scheme was essentially a new one, it had been thought advisable to establish them at intervals.

Profiting by experience, the scheme had undergone a natural evolution. While wholly experimental and tentative, two years' experience of its working seemed to show that this form of relation between the University and industry was to the advantage of all concerned. The tenure of all Fellowships was for two years; but one, which was to expire shortly, was to be continued at double the value for three months, at the end of which time the donors would either take the Fellow and his process into the factory, or continue his Fellowship through a third year at the enhanced rate; and in another case the donors had already indicated their intention to continue it throughout a third year.

There had been so far accepted by the University of Kansas the following Fellowships:—

1. An investigation into the chemistry of "laundering," with the object of saving laundered fabrics: \$500 a year, together with 10 per cent. of the net profits.

2. A search for a new diastase, with an attempt to make a new fodder upon scientific principles: \$500 a year and 10 per cent. of the gross proceeds for three years.

3. Utilisation of the constituents of waste buttermilk, primarily casein, and secondarily, lactic acid and milk sugar: \$500 a year and 10 per cent. of the net profits.

4. An investigation into the chemistry of baking, established by the National Association of Master Bakers, with the object not only of improving the chemistry of bread, but, as well, of providing for the association a trained expert upon whom they could afterwards rely: \$500 a year, together with a sum to be settled by arbitration.

5. An investigation into the constituents of crude petroleum: \$1,000 a year, and 10 per cent. of the net profits.

6. Improvement in the enamel upon enamel-lined steel tanks: \$1,300 a year, together with an additional consideration to be decided upon later.

7. An investigation into the relation between the optical properties of glass and its chemical constitution: \$1,500 a year and 10 per cent. of the net profits.

8. The discovery of new uses for Portland cement and of improvements in its manufacture: \$1,500 a year and a large additional consideration dependent upon success.

9. An investigation into certain glands of deep-sea mammals: \$1,500 a year and an additional consideration to be decided upon by arbitration.

10. The discovery of new utilities for ozone: \$2,000 a year and 10 per cent. of the net profits.

The Fellows for Nos. 7 and 8 had not yet been selected, and Fellowships Nos. 9 and 10 were assured but not yet established.

It must be borne in mind that the Fellowships differed from one another owing to the circumstances and, occasionally, to the idiosyncrasies of the donors. The scheme in its present state might perhaps best be understood by presenting the following specimen of an agreement thereunder, for example Fellowship No. 7:—

Memorandum of Agreement.

"For the purpose of promoting the increase of useful knowledge, the University of Kansas accepts from the A.B.C. Glass Co., having head offices at New York, the foundation of a temporary industrial scholarship to be known as the A.B.C. Fellowship.

"It is mutually understood and agreed that the conditions governing this Fellowship shall be as follows:—

"The exclusive purpose thereof is an investigation into the optical properties of glass in relation to its chemical constitution, to the furtherance of which the holder shall give his whole time and attention, with the exception of three hours a week, which he shall give to work of instruction in the chemical department.

"The Fellow shall be appointed by the Chancellor of the University, the Director of the Chemical Department, and the Professor of Industrial Chemistry; he shall have made previously a reputation in research; he shall be a member of the University, and shall pay all regular fees with the exception of fees for laboratory and supplies, for which the instruction given by him shall be taken in lieu, unless in the opinion of the appointers his demands become excessive, in which case the donor shall reimburse the University; he shall work under the direction and advice of the Professor of Industrial Chemistry; and he shall forward, periodically, through the Professor of Industrial Chemistry, reports of the progress of his work to the A.B.C. Glass Company.

"For the support of this Fellowship, which shall extend through a period of two years from the date of appointment of the Fellow, the A.B.C. Glass Company agrees to pay \$1,500 per year, payable annually to the University on the date on which the Fellow begins work at the University. This sum shall be paid by the University in monthly instalments to the holder of the Fellowship.

"Any and all discoveries made by the Fellow during the tenure of this Fellowship shall become the property of the A.B.C. Glass Company, subject, however, to the payment by them to the Fellow of ten (10) per cent. of the net profits, to be commuted at the desire of either party

through the arbitration provided for herein, arising from such discoveries, it being understood that the Fellow shall be regarded as the inventor. At any time during the tenure of his Fellowship the holder shall, at the option of the donor, take out patents at the expense of the donor on condition that at the time of making application therefor he shall assign his right to the donor under the conditions of this agreement. At or before the expiration of the Fellowship, the business services of the Fellow may be secured by the A.B.C. Glass Company for a term of three years on condition that the terms of such services are satisfactory to both parties at interest.

"In the event of any disagreement between the donor and holder of this Fellowship, it is understood and agreed that the Chancellor of the University, or one whom he may appoint, shall act as arbiter as to all matters of fact, that his decisions shall be binding upon the parties at issue, and that they shall obtain such decision before having recourse to the courts.

"It is also understood and agreed that during the tenure of this Fellowship the holder may publish such results of his investigation as do not, in the opinion of the Company, injure its interests, and that on the expiration of the Fellowship the holder thereof shall have completed a comprehensive monograph on the subject of his research, containing both what he and others have been able to discover. A copy of the monograph shall be sent to the A.B.C. Glass Company, and a copy shall be signed and placed in the archives of the University until the expiration of three years from that date, when the University shall be at liberty to publish it for the use and benefit of the people.

"Signed on behalf of the University of Kansas.

"Date.....

"Signed on behalf of the A.B.C. Glass Company.

"Date....."

Some of the advantages accruing from these Fellowships were that the University gained increased opportunities of promoting research; it obtained three hours a week of gratuitous instruction from men of ability, knowledge, and enthusiasm; the Chemical Department, in particular, obtained the catalytic influence of these men. The manufacturer obtained the advantages of enormously increased laboratory facilities; adequate library facilities, a most important advantage, the lack of which had seriously hampered much factory research; consultative advantages, for the Fellow appointed was at liberty to question specialists in the different fields of chemistry, or in other fields of scientific knowledge; complete freedom from supervisory responsibility over the work; and on the termination of the Fellowship, the services of a man educated to his particular needs. The Fellow obtained all the foregoing advantages ascribed to the manufacturer, and in addition the all-important sympathetic co-operation of the manufacturer, together with inside knowledge of the factory processes, and the University's environment sympathetic to research; also a freedom from all petty interferences and jealousies of shop people, and the pot-shot judgments of factory officials. Finally, if he proved worthy of it, he obtained a position for which he had become, through his training, peculiarly qualified.

Since at the end of three years all work done under any Fellowship must be published free to the public, the public thus obtained new implements of civilization. It was only through the industries that any useful discovery went to the people. The insertion of this clause had been occasionally resisted for a time, but the donor had always in the end acquiesced, when it was pointed out that a really progressive manufacturer would find three years a sufficient start.

Since this whole scheme depended upon sympathetic co-operation, it could only be carried out through a Professor who regarded it as a sacred trust. It was, therefore, positively necessary that the Professor of Industrial Chemistry should, so far as any material sense was concerned, gain absolutely nothing, otherwise his

donors would not trust him with the details of their secret processes, nor would his Fellows trust him with their progress.

The CHAIDMAN said they must all admire the modesty as also the earnestness with which Prof. Duncan had put his scheme forward. He was evidently an enthusiast who wished to do the best for the young chemist and the benefit of humanity at large. Of course, the manufacturer was bound to be benefited as well. Prof. Duncan had spoken of the American manufacturer as he knew him, and no doubt he did know him. Those members of the Society who had been in America would endorse his view, for, however far advanced the chemical manufacturers in America might be in handling materials, so far as the chemistry was concerned in 1904 they were much behind England. In that respect they in England had little cause to be afraid of the American manufacturer. If he made small profits per ton of product but could multiply them by hundreds and thousands, he might be successful for a time, but not in the long run. He might even for some time try to protect himself by a tariff, and get as much as he could out of his fellow-countrymen, but that system could not go on for ever. In fact, the tariff had done great service in pointing out where the weakness lay. This unselfish scheme into which the author of the paper threw all his individuality and knowledge was bound to lead to good results, and the younger members should get into touch with Prof. Duncan, because he had come over to Europe with the view of offering a number of these Fellowships to English chemists. Anyone who was willing to risk some time, and was able to trust to his own capabilities, should try and obtain one. Prof. McDola was unfortunately prevented from being present that night, but wished it to be known that he was strongly in favour of advancing chemical industry by Industrial Research Scholarships.

Dr. E. DIVERS pointed to the importance of the fact that manufacturers had accepted this scheme, and had shown themselves willing to work it. Many chemists who had felt for years the great need for just such a matter, had feared the case to be almost hopeless, because manufacturers were not to be found who would trust their affairs in the hands of someone over whom they had not sufficient control, or outlay money on an investigation the results of which were very uncertain. But they had now learnt that they had only to act on the lines laid down by Prof. Duncan to find themselves able to carry out what was so important for all our technical schools and colleges. They now saw that it was possible, in Kansas at any rate, to get Fellowships endowed, even well endowed, which gave admirable opportunities to young men of promise, to investigate and to work upon problems in chemical technology with confidence, that could they discover anything of value, a career would be opened to them. The scheme presented a promising method for the development of technical institutions, and he congratulated Prof. Duncan upon its inauguration, and upon the success which had so far attended it. There could be no doubt from what Prof. Duncan had said that greater success would follow, and he thought the scheme might be imitated in this country with every prospect of success.

Dr. H. W. WILEY said there were two points of view with regard to industrial education: Should the State undertake the industrial education of its citizens, or let the citizens take care of themselves? These two points of view were well illustrated by the two countries Great Britain and the United States. The United States had become essentially a paternal Government, the view held being that the State should do practically everything; while in this country it seemed to be held that the individual should take care of himself and serve the State, while in the United States the State was supposed to serve the individual and the citizens. At the time of the Civil War, when one might have thought that all energies would be turned to military affairs, the foundations of industrial education were laid. In 1862 an Act was passed in Congress giving to each State a certain part of the public domain corresponding to its population; so that for each member of Congress and member of the Senate, a certain amount of public lands was devoted to each State for the purpose

of beginning industrial education. This was first of all intended to be agricultural, but at the same time it was provided that instruction should be given in the arts and industrial science and also in military tactics. The States could accept or reject those grants as they thought fit, and, in point of fact, all the States had accepted the grant. Some States had administered the trust with great financial success, so that now they had a very large income from the public lands; for instance, New York, which received the largest amount, had kept its lands and leased them, while other States sold them. The State of Indiana, of which he was a citizen, sold the whole of the land for 60 cents an acre, though, had it retained those lands till now, it could have got an annual rent out of them of at least an equal amount. This was the beginning of industrial education in America, and every State now had an Agricultural College in which were taught the mechanical arts of all kinds and also military science. Having founded these schools, Congress proceeded to found Agricultural Experimental Stations in every State, and large grants of money were made to them annually; and at present \$20,000 a year was granted to each State for agricultural education annually and \$26,000 for Experimental Stations. These funds were well utilised. What was the result? These young men were engaged for industrial purposes even before they got their diplomas. Scarcely one ever graduated who had not already a situation in view. They at once began their industrial activity; they did their work well, and made good the result of their training. Thanks to the generosity of the late Mr. Mackay, Harvard University had founded a school of applied science which no one was allowed to enter who did not hold a degree equivalent to that of B.Sc. or B.A. It was, in fact, a school where they would only take trained men and give them additional training in the higher branches of applied science. That seemed to him one of the marks of progress in America. They not only wanted to train the mass of mankind to do industrial work, but to give a chosen few the very highest training which could be given to a young man to fit him for success in industrial life. The school was only just organised, and it was too early to say what it could do, but the first branch it had organised was that of Forestry, having bought a large area of forest land where it took graduates from other schools and taught them the applied science of forestry. It had schools of applied science in agriculture and also in veterinary science, in electro-chemistry and civil engineering, all fully organised, and they would soon be full of students. Thus in America they not only had the State generally supporting industrial training, but the individual. This meant that in the race for success, that nation was going to be foremost which trained its young men best. Up to this time America had not been a scientific country. When he was young, they came to Europe for scientific training, but now crowds of Europeans were coming to America for that purpose—the balance of trade had turned in their favour, because they were offering the most abundant prizes for applied chemistry and other sciences which could be found in the world. That was the hope of American industry of all kinds, the training of the young men, in agriculture first and then in applying science to manufactures. They had a country rich in raw material, with abundant energy and enterprise; and they had money; but now they were going to have science and skill. He believed that every natural resource was now taken up, but it was not going to put an end to their progress. They were going along and were not going to rest content until they could all grow 30 bushels of wheat per acre, as they did in this country. They had no more acres to cultivate, but they had enterprise to make the acres they had more productive, and that was what applied science would do in all branches of production. They did not want more hands, but they would make the hands more skilful. So far as the production of food and clothing was concerned, the capacity of the mouth remained constant, while the capability of the hands was constantly increasing, and we had two hands to one mouth, so that there was no need to look forward to any disaster to the mouth of the future—the hands would take care of it.

Dr. ROBERT MOND said the question of how to bring the higher University education into closer touch with actual manufacturing operations was one which had occupied all University Professors and manufacturers ever since there had been any. It was an extremely difficult question to solve, and the difficulty lay, as Prof. Duncan had pointed out, in the fact that it must remain so entirely a question of personality—of the personality of the manufacturer, the professor, and the research student. Every industrial question which had to be submitted to research work required and opened out a large number of new lines of research, and it was impossible to say beforehand whether the information thus conveyed was in a fit state for publication, or whether it was advisable from the manufacturing point of view to make it public or not. That was the fundamental difficulty. The manufacturer was faced with a large number of questions which might appear to be entirely academical, but would cease to be academical as soon as he tried to experiment with them or asked anybody else to do so. This had always been one of the great stumbling-blocks in the way of getting the University Professor and the manufacturer to work together. The manufacturer was always working in the dark, not knowing from day to day what was going to be the industrial application of the most impossible-looking piece of scientific research. It branched out in all possible directions. One might start upon what appeared to be a clearly defined line of research, and might run into all kinds of difficulties, with regard to apparatus, which had to be solved in order to continue the work, and in the solution of that difficulty an entirely new thing might be discovered. For instance, the whole of the nickel carbonyl process which his father had discovered was based on the fact that the nickel valves of his ammonium chloride process became coated with a black deposit, the examination of which put them on to the track of the nickel carbonyl process. Supposing there were some one working on ammonium chloride research, who got hold of this powder, and began working on it. The employer could not by any possibility claim the benefit of this new process, to which he had no moral claim. It would be entirely the work of the investigator, and he defied any University Chancellor to arbitrate successfully as to what claim the employer would have against the research chemist, or what the research chemist would have on him as to the property in the invention. He heartily congratulated the members of the Society in Kansas in having succeeded in obtaining the services of a personality like Prof. Duncan, who was capable of differentiating these things. When they were able to secure such men to arbitrate between them and to work in harmony they would progress at a much more rapid rate. It was a remarkable thing that higher education had begun by degrading or putting on a lower plane what they were accustomed to look upon as a University education. The whole of what was now called regular post-graduate education implied that the man who obtained his degree was not a finished article—not a man capable of doing research and standing on his own feet; not a man like the students now being trained all over the Continent of Europe, who were fit to become the private assistants to the professors or lecturers, but one who must go in for a second course of University education. Dr. Wiley told them how they were arranging it at Harvard, but it had been done much earlier at the Johns Hopkins University at Baltimore, which only took as a student one who had taken a degree somewhere else. There was a tendency, both at Oxford and Cambridge, to follow suit with research degrees, and it was a moot point whether it was advisable to put our Universities and Technical Colleges of equal rank on a basis of inferiority, so that those to whom they accorded degrees should require additional education before they could be considered the finished product of the University. That involved the whole question of the secondary education which came before it. Should secondary education be received before going to the University, or should it be given at the University during the first year? In England, unfortunately, there was not that co-ordination between secondary and University education which enabled the teaching to be done properly. In some countries they had a system of secondary education, but our students

only had it in a few institutions. Secondary education should be made more general so as to raise the average of knowledge before the University education began. The difference between secondary education and University education was that secondary education consisted of teaching on a regular, well-defined plan, where every hour of the day was arranged for and every subject was properly digested and assimilated for the student; the University expected a man to take his own meal from the menu provided. It was this selecting and choosing of the sympathetic University teacher and going to the place where the subject was treated in the most sympathetic way, which enabled the mind to be formed and independence developed while acquiring knowledge. This stage only began here with the research student. Even now, after 600 years, at Cambridge they were still in a position of flux with regard to the whole question. They had to try to find quite as much the lesser evil as the greater good; but in his opinion the greater good was the teaching in the University of that independence of mind by which a man would stand on his own feet and assimilate the information which was serviceable to him. The University was not there to encourage people to obtain the greatest possible number of marks; the man was not there to pass a competitive examination. That might be all right on the race-course, but not in a University. The object of a University was to gradually prepare men's minds to assimilate knowledge, and to so use it that they could go on assimilating it all their lives. The more a University was made like a school bench, the more that was prevented. There was only one way of getting at any generally applicable scheme of University education, and that was, in the numerous teaching institutions now at work, to make experiments, and of these different experiments they would have to know the constants and be able to determine their coefficients, with as much, if not greater accuracy than in any dilute solution, so that they would be able to find out gradually what was the method in which the human mind, as normally constituted, could best proceed to develop itself for the general benefit of the country.

Prof. C. BASKERVILLE said the work that was being done in America in this direction needed no defence. Their method was not perfect; they knew the defects, and they were trying to cure them. It was simply one of the many ways of trying to knit pure and applied science more closely together. His only fear with regard to Prof. Duncan's scheme was this: if institutions and corporations put into his hands researches and money at the rate of \$2,000 a year each for three years, and he had to stand the mental strain of directing them in 30 different directions, he might lose his enthusiasm.

Mr. GRANT HOOPER said it seemed to him that when they talked about the research chemist they lost sight altogether of the fact that a research chemist was not merely a chemist well trained. An ideal research chemist was a man possessed of imagination, for without imagination it was impossible to do anything in the way of research. He was rather surprised at some of the remarks which fell from Dr. Mond. From the large number of chemists working under his supervision he, surely, could have sorted out a small proportion who were possessed of imagination or resource as it was sometimes called, and it was only of such men that he could ever make anything in the direction of research. In connection with the very problem he specifically referred to, the origin of the nickel-carbonyl compounds, he might have placed that investigation in the hands of a man altogether incapable of seeing to what great result it might lead; he might, in other words, have selected a man who was a very able analyst, but so utterly devoid of imagination as to fail to see the thing which stood straight before his eyes as the result of his work. He took it that Dr. Ludwig Mond was actually the one who did see it, though of course it might have been the chemist making the examination who called attention to the possibilities that resulted from this investigation. At all events someone saw the possibility, and that somebody had the making of the ideal research man. Turning now to a criticism of the scheme as it had been placed before them, he observed that one of the conditions laid down for the selection of these

research men was that they should have proved their capacity as researchers, and he should like to know how this capacity was to be proved—what kind of research work was to be taken as evidence of capacity to deal with the particular problem upon which the man was to be set to work. It seemed to him to be most important if success was to be obtained that a man to be employed upon a particular subject should have his mind saturated with that subject, should, in other words, be acquainted with all that had already been done in connection with the science of the industry or of the matter in hand. It was not a man well versed in general chemistry, not merely a good chemist in other words, but one who, in addition to a good general training, had had his mind specially directed towards the subject of the particular problem. He would say therefore to Prof. Duncan and others who might follow in his path that they ought to look first to the laboratories connected with the industry in question and endeavour there to find among the men engaged in that particular industry one possessed of the imagination and resource which were the first essentials to the solution of problems. In connection with the cement question, for which a scholarship had been offered, he would suggest that among chemists connected with cement works, it was most likely that one would be found who, in a reasonable time, would most nearly approach a solution of the given problem. He quite agreed that there was a difficulty, because the best men were not willingly spared, but, at all events, this particular question should be placed before someone who had already been engaged in the cement or a cognate industry. A purely organic chemist, for instance, would be out of place. Again there were two entirely different questions involved in some of the instances which had been given them; there was the case where a manufacturer said, Is this particular process which I employ carried out in the best possible way? or, Here is a difficulty that I meet with every day, can you show me a means of avoiding it? The other case, altogether different, was that of the utilisation of a substance either natural or of the nature of a by-product so far unused, but which it was desired to turn into money. In this instance the qualifications called for were somewhat different to those demanded in the former case, though again the first essential was imagination. Closely connected with the subject they were discussing was the question, could they merely by education turn out what Prof. Duncan called researchers? He said they could not. A man might acquire chemical skill and knowledge, which undoubtedly formed the foundation on which alone progress could be made, but imagination could not be created where it did not exist. Imagination might be cultivated and developed, but this special capacity as a general rule was most clearly seen in connection with practical, responsible work. It was not until the general education was completed and the man undertook and successfully solved the definite problems which arose in connection with responsible work that it could be satisfactorily settled whether or not he had the capacity which made a research chemist.

Prof. H. E. ARMSTRONG said Prof. Duncan's scheme was characteristically American. Were they to understand, that the steps Prof. Duncan was taking were with the object of helping the particular kind of manufacturer he described, or was the object to help a higher class of manufacturer? At all events the scheme might be valuable as a means of driving the thin end of the wedge, home and of interesting a certain class of persons in scientific inquiry who at present had no understanding of its methods; they must therefore congratulate him on the success he seemed to have achieved. Anything done in such a direction must help; the only question was whether the class pictured ought not to be destroyed as soon as possible. It would be to the advantage of America to introduce a proper class of manufacturer in his place, who understood more or less how to set about the work himself. They had tried here over and over again to interest the ignorant manufacturer and had failed; they would continue to fail until a different class of manufacturer came into existence, until the Universities so altered their methods that the cultured, educated general public were able to understand the position. At the present time, they did not want to ask themselves what they had

to do to succeed in these matters; they had an example of success before them and knew exactly what constituted success. They knew the extent to which Germany had succeeded, not only in chemical industry but in every branch of industry to which scientific method was applicable; and at the present day that included all industries. They knew that Germany had succeeded not through any such means as had been brought forward to-night, but through its system of University training. He did not agree with Dr. Mond that German success had much to do with secondary training. He did not believe, as a matter of fact, that the secondary training was much better in Germany than it was in England. The fact was that the German material was somewhat different from the English. The German would apply himself and work harder than the average Englishman; that was in a large degree the secret of German success. The German was not above his business in the way that so many young Englishmen were; until young Englishmen of position, who commanded capital and who were going into the businesses made by their fathers, were brought up not to be the dilettanti they were at present but to take an interest in things and to know what research was (no average Englishman had the remotest idea what the word connoted), they would not make much progress. He thought they were much indebted to Dr. Wiley; his remarks must have impressed the meeting with some sense of the feeling which pervaded America at the present time, which came out everywhere—the feeling of earnestness and determination to succeed and carry on good work in the future. Dr. Wiley had said that they were going to bring up their young men to be highly skilful; no doubt they were making great efforts to do that. The question was whether a method such as Prof. Duncan had put before them was likely to give that result. Was his scheme of research a scheme of research at all? Listening to the list of subjects on which the Fellows were to work, he had felt that it was not really a research scheme. The list included finding a use for butter-milk and finding new uses for cement. That was not what he should call research. Such inquiries were obviously to be made with the object of extending a business, and were not in any proper sense of the term research work. After all, if they were going to help young men in the future to be of value in works, they ought to train them not merely to apply themselves to subjects of that kind, but to train themselves broadly, so that they could deal effectively with the very large number of problems which came before a man in any average small works. In this country and in America most of the works were run by a relatively small staff of chemists—a very small staff in most cases. A man went into the works to deal with a complex business, not to deal with one particular thing; he was faced with a great number of problems, and he needed to be more or less a man with a business head and at the same time one who had sufficient knowledge of science to develop the various problems which came before him. As Dr. Mond had pointed out, you never knew where you were at the present day, or what would be of value. In listening recently to Dr. Fleming's lecture at the Royal Institution on wireless telegraphy, a case of this kind had been impressed on his mind: one of the most striking points made by the lecturer was that a method which was going to be of great service was the outcome of research on the electrical conductivity of crystals; the unilateral conductivity observed in certain crystals was made use of for the purpose of rectifying the currents by causing them to go in one direction instead of two. For industrial purposes they needed men to be very widely and thoroughly trained. A scheme such as was described might be put into practice to a limited extent, but no man could stand the racket of supervising a scheme of that sort if it were carried very far; and after all, the attainment of success would depend entirely on the kind of man under whom the students were working—whether he were capable of initiating and supervising research work. Prof. Duncan's Fellows might be expected to know to a limited extent what were works' requirements, but they would not be put under works' conditions and be subject to works' discipline; they would not be gaining much which would be of subsequent advantage to them in the works. They would be turning their

attention to some particular subject, which would perhaps be a good thing if it became their future employment; but, on the whole, the scheme did not promise to produce men who were highly trained from a scientific point of view, such as would be required by the manufacturers of the United States in the future. Dr. Wiley had referred to the Harvard scheme, which seemed to be a more promising one and likely to produce men who had really learnt to work as individuals—not merely to order and under direction. They had, however, to thank Prof. Duncan for having brought the subject before them; no doubt his account would give food for thought.

Prof. W. L. DUDLEY said the suggestion of Prof. Duncan was undoubtedly unique, but he agreed with what had been already said about the difficulties, and doubted very much if, as had been stated, it would be possible to get the proper subject attached to the proper research worker. Those who had done research realised that it was like playing an instrument. One man was suited well for one research and not at all for another; each man had his peculiar *forte* which interested him most, and with which he felt he was best able to deal. Two men of the same ability as chemists could not possibly pursue the same research with the same degree of facility and success. He should therefore feel great doubt as to the success of these workers when the subject was picked out for them. He knew many subjects upon which research was needed, and yet at the same time out of the many he knew there were very few he should be willing to undertake himself, because he should feel as though (reverting to Dr. Fleming's lecture) he was not exactly in tune from the standpoint of radio-telegraphy with most of these researches. It seemed to him that the only place to educate a research worker in an industrial process was where he was in contact with the works; he could not get in tune with it unless he was. Now Prof. Duncan might have produced the impression that American manufacturers worked by a sort of rule of thumb method, but no doubt many present knew to the contrary, and he wanted to emphasise the fact that they had an exceedingly large number of corporations which carried on regular scientific work. Some corporations he knew had a large number of research chemists in their laboratories, and they were the successful ones and were becoming more successful day by day. Those whom Prof. Duncan referred to were the smaller manufacturers who were gradually being pushed out of existence. Dr. Wiley had told them they were going to do a great work in industrial education, and, as he said, out of the young men who were being trained all over the United States, probably 5000 or 6000 graduated each year, and they were all snapped up immediately by manufacturers, railroad companies, and engineering corporations. He knew that at the institution with which he was connected they could not supply the demand for engineers and chemists of all sorts and students who had been trained on scientific lines. These men went into these establishments, and if they were the right kind of men, and had been trained properly, the manufacturer would be a very stupid one who did not realise that man's ability and give him an opportunity to do the work he was specially fitted for. Take the Steel Corporation—the great "Trust" about which so much was said—there were men he knew who had come out of colleges within the last ten years, men not over 25 or 26, who were superintending some of the finest plants and getting \$8000 a year, men who had never had any training at all except the college training, and then went in at the bottom of the Steel Corporation's works; their ability was soon recognised and they were pushed on. They would be surprised to see how young the men were who were in charge of works of that character. He believed Prof. Duncan's plan a good one, though he had never tried it, but he did not think it was one which could be adopted generally. The great uplifting of the scientific manufacturer was going to come from the institutions which were carrying on the industrial education of the United States.

Professor DUNCAN, in reply, said that he had listened to the discussion with the most anxious interest, to discover if there were any weaknesses he had not detected. A few additional words about the scheme would constitute a reply to most of the remarks that had been

made. The first action that followed the appointment of the Fellow was usually to send him to his donor in order that he might enter the factory and become practically acquainted with the difficulties to be met. He had taken that action in every case in which it applied, the young man going at the expense of the donor. For example, the National Association of Master Bakers had appointed a Fellow to investigate the chemistry of baking. The first step was to send him on an extended tour of inspection of the best baking practice to be found in Washington, Philadelphia, New York, and Chicago; he was met by the bakers and was frankly told the condition of affairs, because he was recognised as a man in a position of trust. The second step was to place him in a bakery as a workman, and it was only after that, that he proceeded to his research. Wherever it was applicable the man went into the factory until he became acquainted with the actual conditions he had to meet, and from time to time, if necessary, he returned there. It was not to be inferred that all factory problems would fall under this scheme. There were many which could only be solved within the walls of the factory itself, but there were certainly others which could be solved as well, or better, in the University with the sympathetic co-operation of the manufacturers, and those were the only ones in which he was interested. The manufacturers who had established these Fellowships were not Western manufacturers, but nearly all of them large Eastern corporations, and if he could mention their names it would be seen that they represented splendid factory practice; but they realised that their work should be investigated and the processes of the factory improved. The scientific men they employed in the factories themselves were often by that very fact cut off from the power of solving the factories' problems—they could not see the wood for the trees—they were hampered by tradition. They were often men who at the beginning were well trained in contemporary knowledge, but as time went on and they became involved in routine work, and took on executive responsibilities, they fell behind. One speaker said that if he wanted a man to investigate the chemistry of cement with the idea of discovering new uses for it, he should apply to one in the cement business. Such a man would be almost useless unless he had in him that creative spirit which had been referred to. Certainly, if he had that, together with contemporary knowledge, it would be best. He wanted a man who was particularly well informed in contemporary chemical knowledge, well trained; a man in whom he could arouse a creative spark. It was a difficult matter to find such a man. They had been reminded by Dr. Wiley of the progress of industrial education in America, and amongst other things he had told them that such men often became engaged before they

received their diplomas. That was the trouble; too often they were turned out "half-baked." That was why he had to seek abroad for men, because in America there were more opportunities than men, whilst in England there were more men than opportunities, at any rate at a reasonable remuneration. It was unquestionably true that the difficulty of obtaining the right man was extreme. The available man must not only be well trained both in hand and in brain in contemporary chemistry, but he must be at the same time a man in good health, for these men had to work. He must also be a man of positive integrity, and, finally, he must be a sensible and reasonable man. That brought him to Dr. Mond's difficulty, which certainly was one, of the remuneration for results. That could only be met by computation, because no corporation was going to continue to pay the 10 per cent. indefinitely. Manufacturers of the type with which he had to do were reasonable men—they were business men, and it was possible to do business with them; as for the researchers it was quite possible for the man in charge of them to make them feel that with reasonableness only might they expect to succeed in life. There seemed to be a consensus of belief that the best thing that could be done was to leave it to the University. Possibly all that could be done at the best was a crude approximation, but suppose that instead of the man being engaged in this particular relation he were engaged by the corporation itself to make a certain research, how was his contingent remuneration to be secured? It could only be secured on the basis of reasonableness—10 per cent. on the net profits of most innovations in factory practice could not be onerous but 10 per cent. on all factory innovations would not do at all; in certain cases 2 per cent. would be sufficient.

Dr. Mond said that the investigation might lead to an entirely different industry, and the people conducting it might be incompetent to deal with it. If it were left to them they could not take it up. The question was, whose property was the discovery; it was not a question of remuneration.

Professor DUNCAN said that a serious question cropped up with regard to the contingent remuneration. It might be that a man succeeded in carrying out a certain achievement and thereby improved a process in such a fashion that while it gave satisfaction to the donor it did not actually increase his income. How was such a matter to be dealt with? This had been pointed out to him by certain donors, and it had been a subject of great anxiety to arrange the agreement that it should be on a reasonable foundation. Throughout they had been earnestly desirous of making reasonable arrangement, because it was recognised that only in that way could such a scheme succeed.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—8d. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs Bourgeois, Paris (3e.).

German.—1 mark each (with full particulars) to Kaiserlich Patentamt, Berlin, Germany.

I. PLANT, APPARATUS, AND MACHINERY.

Water for power; National and international conservation of—. E. R. Taylor. Faraday Soc., June 15, 1909. [Advance proof.]

THE author began by pointing out that the water power capacity of the United States with proper conservation is not less than 150 million H.P., without considering the storage capacity of brooks. The annual stream flow in the same country is 70 million million cub. ft., of which less than 1 per cent. is restrained and utilised for municipal supply and such purposes, less than 2 per cent. is used for irrigation, 5 per cent. for navigation, and less than 5 per cent. for the production of power. From 85 to 95 per cent. is wasted in floods. This illustrates the kind of waste that is going on all over the world, and typical examples of such wasted resources were described and

illustrated by the author, who strongly advocates the impounding of flood-waters in the uplands with accompanying afforestation of the hills, and the simultaneous conservation of sources of power, which a vast in the aggregate, and which at present are almost entirely uncontrolled and untapped. Many instances were given of the advantages that have accrued from the proper utilisation of this waste water, both on small farms from the impounding of a mere brook, to the damming of great rivers and the consequent enrichment of vast tracts of country. The electrochemical industry in particular would benefit by the creation of cheap and abundant sources of power, on which their very existence depends. The lecturer strongly urged the necessity for this problem being considered internationally. A beginning will be made in 1910, when an international conference will be held at the Hague.

PATENTS.

Filtering apparatus. B. Bramwell, Belfast. Eng. Pat. 2101, Jan. 28, 1909.

THE filter consists of a horizontal cylinder with dished or convex ends, mounted on trunnions and supported by rollers, so that it can be rotated, when the contained filter ed is being cleansed by reversing the flow of the liquid. The liquid to be filtered enters through one of the trunnions and the filtered liquid escapes through the opposite trunnion.—W. H. C.

Filter-press. S. K. Behrend, Denver, Colo. U.S. Pat. 924,131, June 8, 1909.

THE frames of the filter-press are connected together by loose links and move upon horizontal tracks. Means are provided for automatically separating them and forcing them together again.—J. W. H.

Filter-press; Continuous —. C. C. Leclaire. First Addition, dated Feb. 24, 1908, to Fr. Pat. 394,450, Nov. 26, 1907 (this J., 1909, 236).

THE outlet for the solid matter terminates in a conduit, the side of which is formed by a hinged flap which is kept closed against the other side by a spring. The solid matter can only escape when it has attained such consistency as to overcome the pressure of the spring. —W. H. C.

Filters; Construction of —. Suero-Filter-Werk, Suero und Co. Ges.m.b.H. Fr. Pat. 397,114, Dec. 5, 1908.

THE filtering material is prepared in the following manner. A mixture of finely-divided asbestos, pulverised marble or gypsum and an acid, is treated with an alkali, until the reaction is approximately neutral, and then mixed with a silicate as binding agent, a solution of magnesium silicate of 25° to 28° B. being most suitable. Asbestos cloth is coated with this mixture and the whole filter is then calcined and washed.—W. H. C.

Crystallisation vessel; Continuous —. T. Suzuki. Fr. Pat. 397,186, Dec. 8, 1908.

THE crystals separated during the evaporation of the liquid in the vessel, 1, collect in the conical portion, 2, the tap, 17, being closed. As soon as a sufficient quantity of crystals have accumulated in 2, the valve, 17, is opened and the crystals and mother liquor fall into the chamber, 16, after which the valve, 17, is closed again. The crystals are retained by the inclined, perforated draining plate, 18, and the mother liquor is aspirated by the vacuum through the pipe, 24, into the evaporator. If necessary the crystals may be washed in 16, by admitting wash water through the tap, 23, the wash water being afterwards aspirated into the evaporator through the pipe, 24. The tap, 25, is then closed, and after admitting air through the tap, 21, the door, 19, is opened and the crystals are removed.—W. H. C.

Recovering valuable vapours or gases; Process for —. from apparatus or machines from which they are evolved during work. W. G. Perks and The Volatile Solvents Recovery Co., Ltd. Fr. Pat. 397,435, Dec. 15, 1908.

THE object is attained by the use of a double system of ventilation. The first system operates in the immediate

neighbourhood of the apparatus from which the gas or vapour is given off, and which may be partially or entirely surrounded by a screen to keep off air currents. This system aspirates the vapours mixed with only a small proportion of air and delivers the mixture to suitable recovery apparatus. The second system deals with the noxious vapours which escape from the first system into the air of the workroom and aspirates these vapours along with large volumes of air, discharging them into the atmosphere or elsewhere as desired.—W. H. C.

Vacuum; Process for ascertaining the degree of — in receivers. Soc. Centrale d'Electricité. Fr. Pat. 397,440, Feb. 24, 1908.

THE vacuum receiver is connected to a glass globe provided with electrodes between which an electric discharge is caused to pass. The degree of vacuum attained is judged from the appearance of the discharge.—W. H. C.

Distillation; New process of —. A. Montupet and L. Jamin. Fr. Pat. 397,519, Feb. 26, 1908.

THE vapours are withdrawn from the upper part of the still, below the rectifying column, by an injector placed without the still and actuated by a steam jet. The mixture of steam and vapour is then injected into the body of liquid in the still.—W. H. C.

Circulation of liquid, especially in cellulose boilers; Apparatus for producing —. E. Mortend. Ger. Pat. 209,443, Feb. 27, 1908.

THE pump used to effect the circulation, and its connecting parts, are all arranged within the boiler, the movable parts being disposed in a special cover or casing on the wall of the boiler, which cover can be easily detached from outside when it is desired to examine or repair the pump.—A. S.

II. FUEL, GAS, AND LIGHT.

Coaldust [explosions]. W. Galloway. Seventh Int. Congr. Appl. Chem., London, 1909.

MINES less than 500 feet deep are damp; those between 500 and 700 feet are damp in hot weather and dry in cold weather; whilst those beyond 700 feet deep are always dry. Coal dust which first begins to appear in a dry state at a depth of 600 or 700 feet, is formed in all mines, and, in the author's opinion, has been the principal agent in all great explosions in which the presence of firedamp could not be accounted for. A great explosion is initiated in a dry and dusty mine, when a cloud of dust is raised and a large flame is simultaneously projected into its midst by the explosion of a larger or smaller body of firedamp, or by a blasting shot. The author advocates the damping of the dust for a certain distance in front of blasting shots about to be fired, and considers this precaution is not insisted on with sufficient urgency, and that it should not be overlooked even when permitted explosives are employed. Could the deposition of coaldust in roadways be altogether prevented or rendered innocuous, great explosions would become impossible. Dust-tight mine wagons are advocated, conveyed at such a speed that the shaking to which their contents are subjected is insufficient to cause dust to arise. Floors should be watered at frequent intervals, so as to keep them continuously damp. Hygroscopic salts sprinkled upon the coal dust in sufficient quantity to destroy its inflammability would effect the same result as water (see this J., 1909, 511). As a means of preventing the spread of explosions from one district to another, in mines in which water cannot be used, it is suggested that 100 yards of each roadway might be lined with brick or concrete, and kept always wet. G. W. McD.

Solid fuels; Determination of the amount of volatile matter in —. E. J. Constam. Int. Congr. Appl. Chem., London, 1909.

THE amount of coke yielded by, and the moisture and ash contained in average samples of coals (or solid fuels), form data from which the amount of volatile matter ("gaseous content") is calculated.

Different methods of determining the yield of coke are used in different countries; and from one and the same sample different values are thus obtained for the proportion of volatile matter. Consequently, in districts where coal from different places of origin is used, the need of a uniform method of determining the yield of coke is strongly felt. The author and his collaborators have therefore investigated the various methods extant with the different crucible methods, and the Belgian, American, and Bochum methods of determining the quantity, chemical composition, and calorific power of the coke produced.

The yields of coke found by these methods, and the chemical and calorific properties of the coke formed in the crucible, were compared with the coke formed from the same fuels by distillation at 830° C. in a small gas-retort. The composition and the calorific power of the combustible substance in these retort cokes proved to be very similar to those of the cokes produced in gasworks and in coke-ovens, after making allowance for ash and moisture. Pyrometric determinations showed that different temperatures prevailed in the different coking methods in which the crucible was used. Further, it was established that no portion of the coke was burnt in coking by either the Bochum or the American method. When, however, the younger fossil substances, such as lignite and peat, and wood, are coked, the samples should be previously air-dried, pressed into tablets, and then carbonised and cooled to room temperature in a current of hydrogen, carbonic acid, or nitrogen. The experimental results obtained, lead to the conclusion that the differences in the yield of coke by the various methods are primarily due to more or less thorough carbonisation of the fuels. The chemical composition of the coke produced in a crucible from coals is not affected by the composition of the original coal, but depends only on the temperature and

the duration of the heating. The crucible coke produced according to Finkener's method at 700° C., resembles coal more closely than the cokes obtained at 900° to 910° C. according to the Bochum or the American method. The latter approach nearest in composition and calorific power to the cokes formed on the large scale in gas-works and in coke-ovens. The slower rise of, and the lower final temperature in dull platinum crucibles, cause the yield of coke to be greater in them than in polished crucibles. Notwithstanding the contentions of Hinrichsen and Tuczak, and of Geipert, to the contrary, the author is of opinion that it is not possible to find a crucible coking method which will afford the same yield of coke as different working methods, which, indeed, differ among themselves. On the other hand, the author would prescribe as a standard method one which gives a coke most closely resembling in composition and calorific power the gas and oven coke. Such a method is the American one, which is convenient to carry out, is applicable to all solid fuels (including those which carbonise without luminous flames), and affords very closely concordant results in parallel tests. As this method is already in general use in those countries—viz., the United States of America and Great Britain—which produce the most coal, it appears to the author that its general adoption is desirable in all conclusive analyses of fuels. The results of the examination are only comparable for different coals if they are referred to the coal or coke free from moisture and ash. The author therefore proposes in general to take for the volatile matter in a fuel—referred to the dry and ash-free substance—the figure obtained by subtracting from 100 the yield of coke as determined by coking 1 grm. of the fuel in a polished platinum crucible according to the prescription of the American Committee on Coal Analysis. This prescription is as follows: "One gramme of the fresh, undried, powdered coal is heated for 7 minutes over the full flame of a Bunsen burner in a platinum crucible weighing 20 to 30 grms., and provided with a tightly fitting cover. The bottom of the crucible, which is supported on a platinum triangle, should be from 6 to 8 cm. above the top of the burner. The flame when burning free, should be 20 cm. high; and care should be taken to protect it from draughts during the determination. The under surface of the cover should remain coated with carbon; but the upper surface should always keep free from it." Analyses for arbitration purposes made in different places by this method on the same sample show differences for the most part of less than 1 per cent. in the yield of coke, and only rarely of as much as 2 per cent.

Alcohol; Highly carburated — as a motor fuel. O. Mohr. Seventh Int. Congr. Appl. Chem., London, 1909.

A MIXTURE of equal quantities of alcohol and benzene has a calorific value within 10 per cent. of that of an equal volume of petrol. This mixture, however, is unsuitable for use as a motor fuel, since the benzene solidifies in cold weather. By using petrol in place of a part of the benzene, a mixture is obtained which will remain unaltered at temperatures down to -25° C.; it boils at -42°-78° C., and can be used in ordinary carburetors.—A. T. L.

Exhaust gases in motor vehicles; Deodorisation of the —. Frenkel. Seventh Int. Congr. Appl. Chem., London, 1909.

THE chief cause of the production of evil-smelling gases by motor-vehicles, apart from imperfect lubrication, is the incomplete combustion of the explosive mixture in the engine. In well constructed motors about 5 per cent. by weight of the petrol escapes complete combustion, or about 18.75 grms. per h.p.-hour. The author proposes to effect a supplementary combustion in the exhaust box or silencer, with the aid of a catalytic agent. The catalytic material tried was finely-divided platinum, deposited on mountain flax, cardboard prepared from the same, or porous porcelain, bundles of the platinised material being enclosed in an iron cylinder closed at both ends by gratings. For a car of about 25 h.p., an element containing about 30 grms. of platinum would be sufficient. Exhaust boxes of the dimensions at present

use would be large enough to accommodate the contact ment or elements, in the case of cars of average power, t for cars of higher power, both the diameter and ight of the exhaust box would have to be increased. e temperature of the gases is sufficiently high to der the catalytic material active without external at, and the heat developed by the combustion may utilised for warming the car in cold weather, or the terior of the exhaust box may be provided with prot- ing wings to increase the cooling by radiation. The ply of air requisite for combustion is furnished by ans of a ventilator (fan) placed between the motor d the radiator, this delivering air to the contact element ough a system of pipes into which the exhaust pipe the motor opens.—A. III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Wood distillation; Investigations on — P. Klason, G. v. Heidenstam, and E. Norlin. Z. angew. Chem., 1909, 22, 1205—1214.

IN the present communication the results obtained in the destructive distillation of cotton and of sulphite-cellulose from pine (*Pinus sylvestris*), fir (*Picea excelsa*), birch (*Betula alba*), and red beech (*Fagus sylvatica*) woods, are described. In the tests, 1 kilo. of the cellulose in the form of briquettes of sp. gr. 1.2—1.4, was used. The retort consisted of a vertical copper cylinder surrounded by three concentric jackets. The outer annular space was heated by means of a gas burner, and the products of combustion passed down through the middle space, and then up through the inner annular space. The temperature inside the retort and outside (in the inner annular space) was measured by means of thermocouples. The temperature inside the retort was raised to 270° C. in 4—5 hours, and then the outer temperature was kept constant for some time. The distillation was almost completed in 1—2 hours, during which period so much heat was developed that the temperature inside the retort exceeded that outside by about 80° C. (The amount of heat developed was about 5 per cent. of the

heat of combustion of the cellulose.) The retort temperature was subsequently raised gradually to 380° C., the temperature in the annular space being then 400° C. It was observed that the evolution of gas was insignificant below 260° C., but then increased strongly; the amount of gas was still fairly large between 300° and 375° C. and always increased rapidly when the temperature was raised accidentally. The gas evolved between 275° and 350° C. contained about 75 per cent. of carbon dioxide; but towards the end, more carbon monoxide was formed, the carbon dioxide content falling to about 50 per cent.; methane was also formed in larger quantity towards the end of the distillation. The gas did not contain hydrogen or aromatic hydrocarbons. The heat of combustion of the gas was about 3.5 per cent. of that of the original cellulose. The chief proportion of the distillation products came over during the first stage of the process, the amount gradually increasing between 250° and 300° C., and only a small quantity coming over between 300° and 380° C. The chief results of the tests are shown in the following table:—

	Cellulose from:				
	Cotton.	Pine.	Fir.	Birch.	Beech.
<i>Percentage composition of material carbonised.</i>					
Water	4.82	5.6	6.44	6.65	7.81
Ash	0.13	0.41	0.19	0.92	0.77
Organic matter	95.05	93.96	93.07	92.43	91.42
<i>Relative percentage proportions of distillation products.</i>					
Charcoal	38.82	36.93	34.86	33.39	32.91
Carbon dioxide	10.35	12.83	11.94	11.14	11.96
Ethylene	0.17	0.21	0.19	0.41	0.25
Carbon monoxide	4.15	3.40	3.92	3.49	3.80
Methane	0.27	0.27	0.22	0.47	0.39
Methyl alcohol	traces	traces	0.07	—	0.19
Acetone	0.07	0.08	0.13	0.15	0.26
Acetic acid	1.39	2.18	2.79	3.89	3.50
Org. matter in sodium acetate	5.14	4.22	8.50	7.72	8.67
Tar	4.18	4.85	6.28	9.58	7.23
Water	34.52	34.17	29.99	29.35	31.88
Loss	0.94	0.86	1.11	0.40	0.93

It will be noticed that the cellulose from birch and beech yielded more acetic acid than that from cotton, pine, and fir. Also the charcoal from birch and beech celluloses contained about 2 per cent. more carbon than that from cotton, pine, and fir celluloses. (See also this J., 1909, 132, 417.)—A. S.

Kerosene; Relation between the temperature of — and the explosion pressure of the supernatant mixture of air and vapour. W. P. Bradley and C. F. Hale. J. Ind. and Eng. Chem., 1909, 1, 345—351.

SAMPLES of kerosene were placed in a strong brass cylinder provided with a pressure indicator, and after heating in a water-bath to a definite temperature, air was caused to bubble through the oil, and the mixture of vapour and air exploded. Measurements were made over a range of temperature from a few degrees below the flashing point, as determined by the closed cup test, to several degrees above the fire point (ignition point) as determined by the open cup test. The results are given in tables and curve-diagrams. They show that at the flashing point (closed cup), a mixture of air and vapour is produced which will yield an explosion pressure of from 15 to 25 lb., whilst at the open cup flashing point, the mixture gives an explosion pressure almost equal to the maximum attainable with the sample. The flashing point determined by the closed cup test indicates most nearly the temperature at which danger from explosion is to be feared. At the ignition point, the oil vaporises so rapidly that the mixture of air and vapour, rich in vapour, gives an explosion pressure less than the maximum attainable.—A. S.

Pyridine; Commercial — and its value as a solvent K. G. MacKensie. J. Ind. and Eng. Chem., 1909, 1, 360—362.

COMMERCIAL pyridine, which consists of pyridine, picoline and water, was found to be unsatisfactory as a solvent for bitumens and rubber. This is due mainly to the presence of water, which forms with pyridine a definite hydrate, b.pt. 94.4° C. (compare Goldschmidt and Constan this J., 1884, 159), having very little solvent action on bitumens. If the commercial pyridine be distilled, the hydrate comes over at its boiling point, and the distillate obtained subsequently, namely "pyridine" (115°—118° C. and "picolines" (134°—144.5° C.) have a much greater solvent power than the original sample. The "picolines" are superior to pyridine in this respect and in some cases are even superior to carbon bisulphide. The flash- and ignition points of commercial pyridine and its distillation products, as determined in a 4 oz. open tin dish of 2½ in. diam., are shown in the following table:—

	Flashing point, °C.	Ignition point, °C.
Pyridine hydrate (40% H ₂ O)	35	55
Pyridine (b.pt. 115°—118° C.)	17	17
Picoline (b.pt. 125°—131° C.)	25	30
" (b.pt. 131°—136° C.)	33	40
" (b.pt. 144.5° C.)	42	48
Crude pyridine	31	38

THE increased activity in the three great fields—California, Oklahoma, and Illinois—was the dominant feature of the situation rather than the discovery and opening of a considerable new fields. The principal new field to give prominence was the Caddo pool, in North-West Louisiana.

Bitumens; Experimental contribution to the knowledge of the —. G. Maderna. Seventh Int. Congr. Appl. Chem., London, 1909.

THE bitumens contained in the asphaltums from different parts of Italy have similar properties to those derived from other sources. They dissolve partially in alcohol and in ether, and completely in chloroform. The portion soluble in alcohol is a yellowish viscous mass at ordinary temperature, possessing the characteristic odor of bituminous substances; that soluble in ether is a black substance melting at about 60°—70° C., and the portion insoluble in alcohol and ether is a shining black substance, which is inodorous and melts at a high temperature. All three portions contain unsaturated compounds, the iodine value varying according to the origin.

the substance, but being tolerably constant for a particular fraction of a given bitumen. On the other hand, the percentage of sulphur increases sometimes considerably from the less condensed to the more condensed portions. The bitumens give the cholesterol action. From the results of experiments on the distillation of mineral oils in presence of air and of sulphur the ordinary pressure and under increased pressure, the author concludes that bitumens are formed by the action of sulphur on hydrocarbons, leading to the formation of unsaturated compounds. Sulphur may have participated in the formation of bitumens, although not present in the products. The formation of bitumens probably takes place in two stages, *viz.*, (1), condensation of unsaturated compounds, and (2), polymerisation. The action of light on the different fractions of the bitumens is quantitatively different although qualitatively the same: under similar conditions, the more condensed portions are rendered insoluble to a greater degree than the less condensed fractions.—A. Retort [for peat]. L. Augustin, St. Hyacinthe, Canada. Assignor to L. Daudelin, St. Hyacinthe, and Peat, Gas and Coal Co., Montreal, Canada. U.S. Pat. 924,305, June 8, 1909.

The retort consists of a cylinder with a fixed cover at one end carrying a hollow shaft for the removal of the peat, and a removable cover at the other end for charging and discharging the peat which is contained in a loose stridge or cylindrical frame. The retort is mounted for rotation in a brickwork furnace with a central fire grate, a fixed bearing being fitted to the hollow shaft and a swinging bearing for the shaft on the removable cover. While charging and discharging, the open end of the retort is carried by a roller bearing arranged in the brickwork and surrounding the body of the retort.

—J. W. H.

Ammonia and tar; Process of obtaining — H. Koppers, Essen-on-the-Ruhr, Germany. Re-issue No. 12,971, June 8, 1909, of U.S. Pat. 862,976, Aug. 13, 1907.

Gases from the dry distillation of fuels, after being cooled to condense the tar and water, which are removed in a separator, are superheated and led, for the absorption of the ammonia, into an acid bath. This bath is kept at uniform concentration by the constant addition of acid and the removal of the crystals formed, the drainings in the latter running back into the bath.—J. W. H.

Petroleum; Distilling — F. Seidenschmied, Charlottenburg, Germany. Eng. Pat. 10,959, May 20, 1908. Under Int. Conv., Nov. 5, 1907. Addition to Eng. Pat. 10,892 of 1908.

Steam and oil outlets described in the original patent (S. J., 1909, 649) are combined to form injectors or spraying nozzles and are directed against one another at the end of being arranged radially, in order to prevent dead space, where there is no circulation, being formed at the centre of the still.—W. H. C.

Petroleum sludge; Process of treating and separating acid from — J. L. Gray, Elizabeth, N.J. U.S. Pats. 23,427, 923,428, and 923,429, June 1, 1909.

A major portion of the acid is allowed to separate and then drawn off. The sludge is next heated, and steam is injected into the mass. The lighter grades of hydrocarbons rise successively to the top and are removed, leaving a residue of pitch or asphaltum. In order to

facilitate the separation of the acid, the acid separated from a previous operation is used to wash the untreated sludge.—W. H. C.

Nitro compounds; Process of producing — O. Boeters and R. Wolfenstein, Berlin. U.S. Pat. 923,761, June 1, 1909.

See Eng. Pat. 17,521 of 1907; this J., 1907, 1194.—T. F. B.

Petroleum; Apparatus for the industrial manufacture of a new spirit by the treatment of — A. Testelin and G. Renard, Brussels. Eng. Pat. 16,881, Aug. 11, 1908.

See Fr. Pat. 393,554 of 1908; this J., 1909, 133.—T. F. B.

IV.—COLOURING MATTERS AND DYESTUFFS.
